The inland regions are remarkably healthy for stock, which have but few diseases, and, notably in the southern portion, no better or hardier horses can be found in Australia. Some of the journeys made are marvellous, showing the sustaining qualities of the natural grasses. I once rode a small horse—"a well bred 'un"—120 miles in twenty-four hours. Cattle grow large, and the meat is excellent; the wool from the sheep is first-class.

Agriculture.

With the building of railways and other public works, the establishment of the mining industry, a certain amount of coastal agriculture will be profitable. Until there is a local demand it is sheer folly to induce farmers to attempt the growth of the many things that can be grown easily. Agriculture cannot pay the high wages for clearing and cultivating now obtaining.

The Australian ideal of a White Australia prevents the employment of a cheap, suitable indentured labour that otherwise could be used for the growth of cotton, sugar, rice, tobacco, Sisal hemp and other fibres, etc., for which we know the climate and soil are suitable.

It will be seen that the problem of labour is a difficult one that has to be faced.

Mining can afford high wages; stock-breeding does not require much labour and can pay ruling rates. Agriculture must have cheaper labour than Australia can supply. Our standard of living is too high. We must, therefore, seek a people from a country which has a lower standard. Where are these to be obtained? After this great war it seems to me that few countries will have any surplus labour, with the exception of Spain, to which many thousands of its people are returning from South America, where they cannot obtain employment. These men would make good navvies for our new railways, and could afterwards, with their families, be settled on the land in colonies. The country would produce nearly everything they need. Houses are cheaply constructed, and clothes required are few and cheap.

There is one product that may change the whole aspect, and that is wheat. The Australian understands wheat-growing, and likes it because it does not entail hard and continuous work the year round. The cheapness of the land would induce a rush of farmers once they were convinced that wheat could be grown. Experiments with Indian wheat have in a small way been decidedly successful; but it is necessary that demonstrations on a large scale be made, and it is difficult to understand why the Commonwealth, encouraged by what South Australia had recently done, has not during the past three years experimented and settled the question.

If wheat could be grown on the uplands, many of the products of the low-lying 50,000,000 acres of coastal lands would be needed for the wheat farmer. Hence the great importance of testing the wheat-growing capabilities of the country.

The late Mr. Holtze, Curator of the Gardens, stated, after fully experimenting with upland rice, that it was a great success, and would be to the Territory what wheat was to South Australia. Like wheat, rice can be garnered with the aid of machinery.

Cotton, with suitable labour, would be profitable.

The Northern Territory is 900 miles long, 560 miles wide, and has a seaboard of over 1,200 miles, indented with numerous spacious harbours and intersected by many large navigable rivers.

It has an area of 335,116,800 acres. It is two and a half times the size of France, four and a half times the size of the United Kingdom, with a rainfall of 6 ins. on the southern boundary, gradually increasing as one goes north till it is 60 ins. at Darwin.

This vast country is practically unoccupied,

the total population being 3,588, of which 2,143 are Europeans, and mostly employed by the Government in Darwin and its neighbourhood.

The exports are gold, silver, copper, lead, wolfram, tin, fish, pearl-shell, trepang, cattle, horses, sheep, and buffalo-hides.

It is estimated that there are between 20,000 and 30,000 aboriginals roaming about this vast land.

CLIMATE.

The climate on the coast is hot and humid, but not nearly so bad as in similar latitudes north of the Equator. There is nothing to prevent white races living and thriving, and I do not believe they will degenerate physically; indeed, it is surprisingly healthy, so much so that the medical officer claims it to be superior to other portions of Australia. It is true that the death-rate per 1,000 is the lowest, but then we have no crowded cities, and the people lead open-air lives. There are men who for the past thirty to thirty-five years have worked hard, lived hard, and never been away for holidays.

The inland plateau has a drier climate, the rainfall being so much less; and it is absolutely a white man's country.

The wet season extends from October to April, and the dry or winter from May to September, during which period nothing more than a few drops of rain ever fall—in fact, the skies are cloudless both day and night.

South of lat. 17° winter rains do fall, but in no great quantities—sufficient to keep the grasses fresh. The winter is most bracing and healthy, except on the coast when it is the fever season, caused by chills, caught in many cases through insufficient bedclothes, the temperature falling to 56°, and the maximum being 89°.

At the head of the Roper and further south it often falls below freezing-point. In the MacDonnell Ranges I have recorded 18° or 14° below freezing-point.

The maximum shade temperature on the coast or tropical portion in the wet season is 96°, and the minimum during the night 65°.

CLASSIFICATION.

Coastal country, 75,000,000 acres, well watered, good soil along creeks and rivers, tropical vegetation and coarse grasses, parts metal bearing and probably coal bearing.

Eighty million acres, good pastoral country, often rich volcanic soil, well grassed basalt, sandstone, and limestone hills, wide plains and river flats, and first-class pastoral country, open, well grassed, rich soil.

Eighty-seven million acres, fair to good pastoral country, leaving about 90,000,000 acres of spinifex scrub and sandhill country, with patches of inferior pastoral country, badly watered, and uncertain rainfall. Parts metal bearing.

I will now take you, illustrated by pictures, many of them from photographs taken by myself, for a rapid run through the country, commencing at the southern boundary.

From Oodnadatta, the terminus of the railway, the traveller passes over fair pasture-land, high stony tableland, intersected by large sandy creek beds which contain fine water-holes. To the east is a remarkable group of springs—hot, cold, and mud—the Dalhousie Springs. The tableland is scantily clothed with grass, edible shrubs and bushes, and although it has a rainfall of only 5 ins., cattle and horses are bred and fatten, and ofttimes top the markets. At 808 miles from Adelaide Charlotte Waters telegraph station is passed, and on crossing the boundary line one is struck by the sudden change from open stony tableland to a country where trees, grass, and bush are growing in profusion, and the morning air is filled with the songs of many birds, a marvellous change of scene, giving promise of fairer lands as the rainfall increases the further north we travel.

Along the Coghlan Creek there is rich pasture-land, salt and cotton bush, grasses and herbs of many descriptions. Water of the finest quality can be obtained at shallow depths. We are still within the great artesian basin, which a few miles to the east has been tapped at a depth of 1,250 ft. in the Anacoora bore, yielding 700,000 gallons in twenty-four hours.

Onwards through mulga scrubs—an edible bush—open plains, high sandhills, and stony rises for ninety miles, having crossed the large sandy rivers, the Goyder, Finke, and Hugh, all of which send their flood-waters to that great sink, Lake Eyre, in South Australia, a salt lake over 200 miles long, lying 15 ft. below sea-level.

After crossing fair pastoral country for 200 miles, the remarkable MacDonnell Ranges are met with. Away to the south-east is a region of about 10,000 square miles of high sandhills,

which might almost be termed a desert, but for the fact that it is clothed more or less with bushes, and water can be obtained by sinking. It is intensely hot. I once crossed it in the middle of summer when the thermometer registered 127° in the shade. I and my companions were two days without water in this intense heat. To the south-west the country is sandy, but there are some good freshwater springs, and it is fair stock country, with several prosperous cattle-men stationed there, who breed cattle and horses, the latter of great stamina and bone. Adelaide is the market.

After crossing the James Range the high sandhills are left behind, and the country is decidedly better—undulating plains, slightly stony, and intersected by numerous watercourses, and hills richly grassed. There are several permanent springs and abundance of water obtainable at shallow depths. This good country has a width of about 150 miles east and west. The rainfall has now increased to 11 ins., and at 989 miles the saddle of the MacDonnell Ranges is crossed at an elevation of 2,500 ft. above sea-level, the highest point on the road from Adelaide to Darwin.

The southern barrier of the MacDonnell Ranges is of a most remarkable character, as it rises out of the plains to a height of 1,000 ft. or more, like a wall through which, at intervals of six or eight miles, a fissure or opening has been made, out of which a creek emerges on to the level plains. This range extends east and west, and the openings are called gaps—Temple Bar, Emily Gap, Jessie Gap, Heavitree Gap, through which the north-south railway must be built, there being no other practical route through these ranges.

The rock is of red quartzite, dipping at very steep angles, and resting on gneissic granite. Passing through these gaps, low ranges of granite and metamorphic rocks are found, which gradually rise till on the saddle the height is 2,500 ft., and the great inland plateau is entered upon.

The MacDonnell Ranges lie south of latitude 23°, and are about sixty miles wide, stretching eastwards 150 miles, and westwards nearly 200 miles. They attain their greatest elevation and their most steep and rugged forms of development in the neighbourhood of Alice Springs. The central mountain from which flow the creeks which drain that region is called Bald Hill; it is between 3,500 and 4,000 ft. high. The range splits up into branches from this locality, trending east and west like the fingers of a hand, and having distinctive names, with about 20 mountains, none of whose elevations is less than 3,000 ft., and some over 4,000 ft.—one is said to be 5,000 ft. high. Mount Brassey, which I named after Lord Brassey, is 1,800 ft. above the valley at its base. Between these ranges are luxuriantly grassed valleys, making an ideal stock country. Water is obtainable at shallow depths in the creek channels.

A most remarkable gorge near the eastern end of the ranges, which I named after my wife, Glen Annie, through which the Hale River passes, is the largest of the fissures referred to. It cuts through a quartz anticlinal, forming a fissure only 10 to 15 yds. wide in places, with precipitous walls 400 to 600 ft. high. It has a length of five miles, and sometimes widens out to 3 chains. It is absolutely impassable for horses or camels. There are permanent waters in it on which the sun never shines.

The Arltunga goldfield is situated about forty-five miles from Alice Springs, and has yielded a fair quantity of alluvial and reef gold worked under the most primitive conditions. From the White Range, which is an immense auriferous quartzite ridge, the richer parts are broken down and carried in tin dishes on the heads of aboriginal women to the valley, bagged and conveyed on camels to the small battery a few miles distant.

Immense areas of these ranges are metalliferous, gold, silver, lead, copper, and mica; but until the railway passes through, the difficulties of transport and the cost of all mining requisites are too great to allow of any extension of the mining industry. The general geological structure is metamorphic and plutonic primary rocks.

Camels bear a very important part in the settlement and development of the drier regions of Australia—in Queensland, New South Wales, West Australia, and this Territory. They carry on an average 5 cwt. each, and travel fifteen miles a day, and can go for long periods without water. On one of my exploring expeditions, when I had a party of fourteen and forty-two camels, heavily loaded, we crossed the Great Victoria desert, accomplishing the marvellous feat of traversing 550 miles in thirty-five days, each camel during that period having had only 7½ gallons of water—only one died. The camel is a fine beast for riding, and, as you will notice, we sit in quite a different position from that usual in Egypt. I once rode a camel 480 miles in seven days.

The aboriginal inhabitants of the Territory

are black in colour; in the southern and central divisions they are few in number, but of fine physique. In the coastal region there are, it is estimated, over 20,000, most of them roaming about at will within the limits of the tribal divisions; a few employed on the stations, and numbers hanging about the mining camps and settlements. Without them the white women of the territory would have a hard time, as white domestic servants are almost unobtainable.

The natives are nomadic in their habits; they have no settled place of abode, no permanent houses or shelters, and wear no clothes; they subsist on game and certain vegetable roots, seeds and fruits.

I hold rather a high opinion of the latent possibilities in these people, and believe that if they were taken in hand properly, and kept free from the contamination of European and Oriental civilisation, a fine body of agricultural labourers could be evolved, perhaps setting at rest the embarrassing question of how to get labour for the tropical regions. We know they are expert in the use of tools, they have been taught to build houses, to make galvanized-iron water tanks. Their original manufacture of canoes, strong rope baskets, fish-nets, shows their intelligence and cleverness.

I submitted a scheme to the Commonwealth Government, suggesting that Melville Island, which contains about one and a half million acres, and on which some 15,000 buffaloes are running wild, at present being shot for the hides only, be set apart as a reservation, and all the natives gradually removed there, and, under capable men, trained as agriculturists, etc. This scheme was not approved by the responsible officers, who, though eminently scientific and authorities on the habits and customs, have, I may be pardoned for saying, not the practical knowledge to qualify them to express a decided opinion on a scheme of this kind. It cannot be denied that this Australian native has never had a chance. Mission stations, while doing good work, are naturally limited in their spheres, and cannot control the natives, who can go and come as they please; while on an island, with the unlimited powers and resources of the Government, the natives could never get out of control. Melville Island therefore offers a unique opportunity to demonstrate whether the native can be civilised and preserved, or whether he must simply die out; and Australia would at least be able to say: "We have tried to save the people whose land we have taken," and remove a stigma from our records.

To return to our travels. On the plateau, after crossing the saddle of the MacDonnell Ranges, we are in a fine pastoral country with a good soil, which should be suitable for the growth of cereals. The climate is good and the rainfall is increasing. Under modern conditions of railway management, the distance of 800 miles to Port Augusta is not too great for the economic transport of grain.

The northern route leads over very easy country, with a slight fall for 110 miles, where the elevation is 1,490 ft. In the next thirty miles there is a rise of 230 ft.; twenty miles further a rise of 30 ft., until we again find ourselves 1,756 ft. above sea-level. Then a declining elevation becomes constant right to the coast. At Barrows Creek telegraph station the height is 1,724 ft. The country passed over for the last 100 miles has been somewhat mixed, some of it being fair, while a good deal of poor sandy country is met with. To the westward are ranges with good valleys and a lot of poor spinifex areas, but all capable of carrying some stock. We have also crossed two large belts of metalliferous country, in which gold has been found, promising when the railway passes along to develop into several mining fields. The poor country one sees impresses one unduly, for it would be hard to convince the traveller on a hot summer day that within a day's ride there is a land of great beauty and value. Some forty miles off the road, after crossing Spinifex, sand-plains, and hills, we find good country. Riding along the valley of the Spence, on either bank grow large trees confusing in their variety, luxuriant grasses, wild flowers and delicate ferns; on our right, about a quarter of a mile away, running parallel with the creek, is a high range of hills rising abruptly, with white lime trees and vegetation growing to the very tops, and flowering creepers overspreading the rocks. After passing through several gorges of great beauty we cross the dividing range. It is here that the Frew River commences. We rode for thirty-five miles along the Frew, which was running, passing several large sheets of water. Birds were very numerous. Twenty-five miles below the station is a lake some two miles long. Wild-fowl of every sort were on its bosom, while on its banks we saw pigeons, kangaroo, and emu. The grass and foliage, rich and luxuriant, are made green with running rivers and gracious with temperate air. Still further on is the Elkedra River, the valley of which is almost as

ich in herbage as the Frew. We found Mitchell grass, silver grass, kangaroo grass, blue grass, mulga grass, barley grass, salt bush, blue bush, mulga, herbage, and various creepers and runners; altogether a rich and beautiful country, making it hard to realise that we were 1,300 miles from Adelaide, and in what was supposed to be desert country.

To Powell's Creek, at 1,431 miles, we passed over alternately good and poor country, with a rainfall of 15 ins. to 18 ins. Thirty miles before reaching Powell's Creek there are some fine ever-flowing springs—Helens and Renners—surrounded by a large extent of exceedingly fine and well-grassed country. The geological formation indicates the possibility of artesian water being obtained by boring.

Away to the eastward for 350 miles, right to the Queensland border, stretches a magnificent pastoral country, consisting of downs and plains clothed with Australia's best grasses —Mitchell, blue, and Flanders. Barkly Tableland occupies a part of this region, which is capable of carrying 10,000,000 sheep, and when a railway is built to the proposed new port at the McArthur River, sheep will take the place of cattle.

To the westward lies the great pastoral district known as the Victoria River district, a fine, well-watered area clothed with Mitchell and other good grasses and edible bushes. The area is about 40,000,000 acres, with a certain rainfall of 20 ins. to 30 ins. The development of a large portion is being undertaken by English capitalists, who have bought the stock and leases, and are erecting freezing works at Darwin to enable the meat to be shipped to England. South of this district is good sheep country, unoccupied because there are no natural waters.

From Powell's Creek northwards the country is nearly level and well grassed, but not good enough to enable the traveller to imagine the magnificent country lying to the west and to the east.

Daly Waters telegraph station, at 1,591 miles, is typical of the telegraph stations. A dead tree in front of the building still shows the large "S" cut in by a member of Stuart's party in 1862, and which is held in great reverence by bushmen. The soil is good, the grasses good; stock doing remarkably well, especially horses, but there is no permanent surface water, though water can be got by sinking.

A lot of sandy, open forest country with inferior grasses is passed during the ninety miles to the Elsie. Yet with water it is all able to carry stock, and might grow wheat; the sandy loam, with a rainfall of about 25 ins., warrants a trial being made. It is a high, dry land with a fine climate. The Elsie is one of the heads of the Roper River, and has rich soil and luxuriant grasses in its valley. Limestone is the prevailing rock. Thirteen miles further takes us to Bitter Springs, really the source of the Roper River. Here are many springs bursting up through the white limestone, and flowing in strong streams into the main channel. The water is slightly saline, contains also magnesia and lime, but is palatable and fit for domestic use. Just here the experimental sheep station has been formed. Some 20,000 acres of rich black soil fit to grow anything surround the springs. Maize and such-like fodder could be grown quite easily. Seventy miles over a lot of poor country brings us to the Katherine River. Although the bulk of the country for fifty miles as seen from the road is poor, there are large areas of what look like fine wheat lands stretching away on either hand. The soil is rich reddish loam, and the grass grows about 3 ft. to 4 ft. high and thick, and level as a crop of wheat. Forty miles before reaching the Katherine we pass a promising mineral belt, recently discovered, in which rich tin ore is being mined. The Katherine may be considered the outer fringe of the tropical or coastal belt. The soil is good, suitable for agriculture, well watered; and here again wheat should be tried. The rainfall is 40 ins.

Onwards to Darwin the road leads through a metalliferous area, consequently the country is poor, except in patches along the creeks and rivers; and it is owing to what is seen from the road that some travellers have condemned the Territory in their ignorance, not knowing that rich and extensive plains are to be found on the rivers to the right and left. The country away from the hills may be described as level, open forest, good soil of a light nature, and, judging from the luxuriant growth of grass and trees, must be suitable for agriculture.

Rivers.

To the westward, about fifty miles, is the mouth of the Daly River, which is navigable for light-draught vessels for about sixty miles, where there is an extensive belt of rich soil, on which the agricultural settlement is being established. There are some good copper deposits, not now being worked. The river drains a vast area of country, and the enormous floods that sweep down during the rain season make navigation both difficult and dangerous.

The Katherine, which heads from the sandstone tableland some 250 miles inland, flowing through a volcanic area, joins the Daly; so, too, the Edith, the Fergusson, Cullen, and many of the creeks of the mineral belt. There are some hot springs. The Flora, coming from the south, is an ever-flowing stream of great volume, in which is a fine fall, which may be used as a power-producer and for irrigating a large area of extremely rich agricultural land in the vicinity.

When the time and conditions are ripe, irrigation will be easily applied to make agriculture in the coastal regions a sure, safe, and profitable occupation. I know of no country where the waters can be more easily and cheaply used for irrigation.

Further west is the Fitzmaurice, about which little is known.

The Victoria River, near the West Australian border, appears, on looking at the map, and has been described as the most important river in the Territory; but later information somewhat discounts this idea. The mouth or entrance is twenty-six miles wide, and the navigation is dangerous, being obstructed by shifting sandbanks and ever-changing channels. It is, like the Daly, subject to bores. With these difficulties overcome, it would be the outlet for the great rich district surrounding its headwaters, and would be navigable for large vessels for fifty miles, and by suitable shallow-draught boats for a further sixty miles.

Eastwards from Darwin, forty-five miles, the mouth of the Adelaide River is passed. This river is tidal and navigable for vessels drawing 13 ft. for over sixty miles, winding its tortuous way through magnificently grassed plains, more or less subject to inundation, suitable for agricultural and pastoral pursuits. It is a most magnificent rice country, equal to the best in Saigon; with suitable labour conditions, a large population could be settled here. Many buffalo roam at will over these vast plains. It is near the head of navigation where the coffee and rubber plantations were established, and only failed through want of labour and transport facilities.

A squatter here has proved the great suitability of the country for successful and profitable pig-raising.

The next rivers of importance are the West, South, and East Alligators. Our steamer anchored twelve miles inside East Alligator, and we proceeded in a launch for fifty miles further. The river is tidal and deep, and could easily be made the channel for conveying the produce of an extensive area of rich country.

The vast plains, extending as far as the eye can reach, clothed with a dense growth of grass, more or less subject to inundation during the wet season, are the home of the buffalo, which are the progeny of half a dozen turned loose when the settlement at Port Essington was abandoned. They increased so rapidly that over 100,000 have been shot for their hides alone, providing good incomes to the shooters. It seems a great waste that such fine animals should be killed merely for their hides, and their carcasses thrown aside. I see no reason why, under proper management, the breeding of these animals could not be made a profitable and permanent industry. The hides are easily tanned and valuable, the meat yields a dark rich extract, the bones and offal could be turned into manures. At present the carcasses remain where the animals are shot, only providing food for the natives employed by the hunters.

Near the head of this river, and at the foot of the sandstone tableland, which attains a height of 1,800 ft., is an aboriginal reserve under the control of a man of long experience—one of the most noted buffalo shooters. He speaks most hopefully of the natives, who do all the work of the station, building houses, yards, huts, cutting and carrying timber, clearing scrub and cultivating the ground. In the garden grow most luxuriantly cabbages, carrots, beetroot, lettuce, beans, cucumbers, celery, sweet potatoes, English potatoes, tomatoes, pumpkins, melons, peanuts, maize, pawpaws, bananas, citrus fruits, mangoes, custard-apples, pineapples, almonds, tobacco, millet, cotton, and Sisal hemp.

The next point of importance touched was Port Essington, where the military post was established in 1839. As we entered the harbour we were signalled by a lugger; the master—a trepang and pearl-shell fisher—reported that a white man had been killed by the natives some 100 miles to the eastward. It is a curious coincidence, and an evidence of the little change that has taken place in the conditions of life on this lonely coast during the past thirty years, that when I visited this place thirty-two years ago it was with a party of police, who were searching for natives who had killed a white man on Croker Island.

Steaming along this interesting coast-line amongst beautiful isles, we passed the Liverpool River, on which is some good country, the Blyth, and the Goyder, which is the most important river flowing into the north coast from

Arnheim Land. I explored this in 1883, and found much good land and numerous very hostile natives, who attacked my small party several times.

The Goyder flows for forty miles through fine, richly grassed, black and red soil plains. No finer soil can be found in the Territory, or even in Queensland. Yet, owing to the labour question, there is no settlement of any kind; the country is quite unoccupied except by the natives.

For over two hundred years the Malays came to this coast every year for trepang and pearl-shell; they founded no settlements, but evidence of their visits is found amongst the natives and trees and plants from their island homes.

There are some fine well-sheltered deep-water harbours along this coast, until we round Cape Arnheim and head south 200 miles to the Roper, which is the best known river, as it was used for the conveyance of the material for the construction of the overland telegraph line for a distance of eighty miles from its mouth, where vessels of 1,500 tons burden discharged cargo.

The Roper heads from the same sandstone plateau as the Katherine, one flowing east, the other west, and drains a large area; consequently the flood-waters are heavy, and the silting up of the channel at the mouth is considerable. At the entrance there is a bar of sand and mud, the depth of water at low tide being 7 ft.; the rise and fall of tide is 7 ft. After crossing the bar there is deep water, in places 60 ft.; for twenty-five miles beyond that 8 ft. at low water over certain bars and shoals. The river is tidal, and is a very fine waterway, many of the long reaches being over half a mile wide.

From the head of navigation, where the fresh water falls over a rocky bar (the flow of water is so great that the water on the river is fresh enough to drink within forty miles of the mouth), the valley, bounded by high and picturesque ranges and mountains, extends for 100 miles to the telegraph line, embracing some large areas of good soil and some fine pastoral country. The river has several channels and deep holes, ten and more miles long, shaded with magnificent timbers. This valley will in the future carry a fairly large population, and then the river will be largely used.

It has been stated by some of the recently appointed officials that the Roper can, by locking, be made navigable right up to the telegraph line, 160 miles. This is not possible, as the fall in this distance is 425 ft.

The river that is destined to play the most important part in the development of the Territory is undoubtedly the McArthur, which flows into the Gulf of Carpentaria, 110 miles south of the Roper. Off the mouth of this river lies a group of islands—the Sir Edward Pellew Islands—which contains a very fine deep-water harbour and safe anchorage, being completely landlocked.

It is proposed to connect this harbour with the mainland by a railway, crossing several islands and the intervening channels, and the various salt-water channels forming the delta of the river. Until proper and complete surveys and tests have been made, it is not known whether this will be too costly or not. In the meantime it is proposed to establish a shipping place inside the mouth of the river, where there is a very suitable site for a town and wharves.

The railway would start from this point and follow the valley of the river through good country for 150 miles to the great pastoral plateau and junction with the main lines, as explained earlier. This port is the natural outlet for over 200,000 square miles of pastoral, agricultural, and mineral country, capable of supporting a large population, and carrying over 10,000,000 sheep and one and a half million cattle besides horses. The Commonwealth Government is seized with the importance of this outlet, and I shall not be surprised if this is the next railway built in the Territory.

I look forward with confidence to the time when this port will rival in size and importance Townsville in Queensland, as it is easier of access and controls a much larger area, without the possibility of opposition from any other port. A large extent of good agricultural land could be irrigated and brought under lucerne. The rainfall is 28 ins., and the climate is healthy, and probably the most agreeable of any port in tropical Australia. It has the advantage of being within the artesian area, flowing water having been struck at 415 ft. by boring.

One cannot speak too highly of the country to be served; no better grazing country exists than the Barkly Tableland, which is from 600 to 900 ft. above sea-level, and is being rapidly improved and stocked with cattle and sheep—already there are 200,000 head of cattle and 70,000 sheep. In the not distant future the McArthur River must be the port of shipment for frozen meat in large quantities.

To Summarise.

Briefly put, the Northern Territory has magnificent harbours and rivers. It abounds in minerals; there are millions of acres of rich agricultural land awaiting development. There are vast stretches of uplands clothed with Australia's best grasses, capable of supporting millions of cattle, sheep and horses, only needing railways and the facilities for getting produce to markets, and the introduction of capital and suitable labour. Men and money are all that is needed to add a prosperous new State to the Commonwealth.

It is within ten days' steam of the great Asiatic markets, and a week nearer to the European markets than is Sydney or Melbourne, and any of my hearers who may be tempted to invest money or go there will find it full of possibilities which will readily respond to proper treatment, and they need have no doubts about the climate.

DISCUSSION.

The Chairman (Sir George H. Reid), in opening the discussion, said he had been intensely interested in the paper, which possessed the invaluable attribute of being written by a man who had been there, a very great advantage compared with most of the addresses that were heard in London. The Northern Territory was one of the remaining tough propositions which Australia had to solve; but fifty, sixty, or seventy years ago many places in Australia which were now the scenes of prosperous industry did not look a bit better than Northern Australia did at the present time. In the early days Australia was thought to be an almost universal desert, and it was one of the marvels of the Commonwealth that, as years had gone by, the "desert area" had been so wonderfully lessened. Labour questions in the Northern Territory would, of course, have to be considered. There were so many more attractive places in Australia for comfort and luxury and everything else that everyone ran after, and which everybody thought no one else should run after, that the Northern Territory was greatly handicapped; but that it would become one of the most important parts of Australia he had not the slightest doubt. He remembered in his young days in New South Wales that old colonists told him wheat could not be grown in districts like Wellington, and that they did not know what could be profitably done with them; nevertheless they were among the richest districts in Australia at the present time. The possibilities of the pastoral industry in the Northern Territory were immense, and it was necessary to bear in mind that in the history of every part of the world the pastoral industry was the safest and best foundation for future development. That was so in the times of Abraham, and it was just as true at present. As the pastoral industry developed, a mixed sort of industry, of agriculture with pasture, arose. That very simple law to begin with, the development of the great pastoral possibilities, which did not require any statesmanship but only a slight knowledge of the way in which communities grow, should be applied to the Northern Territory, because it was the very best foundation that could be adopted. It was there that the wealth of the Northern Territory was most visible, and when those industries had been fully developed it would be astounding how easy it would be to make further advances. The author was one of a noble band of pioneers and explorers, whose names ought not to be forgotten.

Lieut.-Colonel the Hon. Sir James Newton Moore, K.C.M.G. (Agent-General for Western Australia), in proposing a vote of thanks to the author for his interesting paper, said it was essential in connection with the development of any new country to profit by what had happened in the development of other countries, and it was therefore necessary to bear in mind, in connection with the development of the Northern Territory, that the pioneer of all industry, as the Chairman had stated, was the pastoral industry. Before, however, the pastoralist appeared upon the scene, pioneer surveyors and explorers like the author had to open the way for him, and then the miner and the prospector followed. The Commonwealth authorities would have seriously to consider what they should do to encourage the prospector in the Northern Territory, and in that respect they had the advantage of the experience of what Western Australia had done in this direction. After the pastoralist and the miner became established the agriculturist came along, but the agriculturist had rather a stiff proposition so far as the Northern Territory was concerned. If the experiments that the author had suggested in that connection were carried out, it would undoubtedly be to the benefit of all concerned. He was not altogether in accord with what the author had said in regard to the question of native labour, probably because he had not had Mr. Lindsay's experience. In Western Australia an endeavour had been made to give the natives a chance by the Government purchasing a station and giving them an opportunity of running it for the purpose of seeing whether it was possible for them to work out their own salvation. As an old surveyor he desired to express his very great appreciation of the work the author had accomplished. In 1892 he (Sir James) was a youngster in the survey department of Western Australia, and about fifty miles due east of Coolgardie he came across what was known as the Slate Well. There were no signs of human habitation, but he discovered some fresh tracks of camels there, and in a little tree he found an empty bottle of Lea & Perrin's Worcester sauce with Lindsay's name on it. That was twenty-

three years ago, and up to within a few days of the present meeting he had never had the opportunity of shaking hands with the owner of that bottle of Worcester sauce. He would not guarantee that it contained Worcester sauce, but it was a Lea & Perrin's bottle, and if the author and his party, as he had stated, only had seven and a half gallons of water in fourteen days he would probably be glad of a drink of something a little stronger.

The Right Hon. Sir William MacGregor, G.C.M.G. (late Governor of Queensland), said that to him the most interesting question connected with the Northern Territory of Australia was the relation between that land and mankind, whether with respect to the white man or the coloured man. He gathered the author inferred that it was quite possible for the white man to live and work in Northern Australia. He (Sir William) had seen a great many men working hard and well in that Territory, but that did not by any means settle the question whether Northern Australia was inhabitable by a white race. Not very long ago Dr. Breinl, the medical officer in charge of the School of Tropical Medicine that had been erected on the east coast of Queensland, told him he had been asked by the Commonwealth Government to give an opinion on the question, and he sought some advice as to the answer he should give. He advised Dr. Breinl to say that it was a question that could not be answered until at least four generations had lived in the north. The white woman had not any coloured assistants to help her in her household duties, and he was sure all the ladies present would sympathise with a white woman who had to live in a house built principally of galvanised iron, and who had to do the cooking, the washing, the ironing, and look after her husband and her children. He had never hesitated to point out to politicians on the other side of the globe that that was at present the weak point with respect to the peopling of Northern Australia with a white race. Woman had not received that consideration which she deserved, and must receive, in connection with that great question, if a white race was to people the northern part of the continent. The author had mentioned the fine physical proportions of some of the native races, and he had noted that fact himself. There were on Mornington Island, in Queensland, natives that were still living in their original primitive condition. He visited them about two and a half years ago, and, according to the report of the protector of the aboriginals there, he was the first white man that had ever seen their women and children. They were a very fine race. He found that on many of the stations in the far north-west, on the Barkly Downs, for example, many natives were employed as stockmen, and received as high wages as the white stockmen. He visited all the native camps, going from Winton over to the Northern Territory, up the Georgina and down the Gregory, and across the Gulf of Carpentaria, and found that whereas there would be as a rule fifty or sixty men and women in a camp, there were only about three or four children. It was a most unfortunate thing that the race was dying out; in two or three generations, at the present rate, the native race would be practically extinct. The mission that was likely to succeed best in the Northern Territory was the one at Mapoon. That mission had adopted the principle of keeping the natives about the mission for a certain length of time, then putting them out on the land and assisting them for twelve months in building houses, and also by giving them seeds and plants, and at the end of that time they were left entirely to their own resources. When he visited the mission he found the natives were growing vegetables and fruit, and marketing them in Thursday Island. One of the inevitable difficulties in connection with peopling the Northern Territory of Australia with a white race was the heat of the sun, and there were two points in that connection that it was hard to get rid of, the first being the physical and chemical results of exposure to the sun's rays, and the other the diseases that were peculiar to such a climate. So far as Queensland was concerned, he did not know of any other country that was equally healthy for both man and beast. Very few diseases existed, and of those some were more or less new to the medical faculty; hence the foundation of the newly-erected School of Tropical Medicine at Townsville. That would enable them to deal with such things as the disease due to the hook-worm, which had been mentioned in many papers in this country during the last two or three years. There were a few diseases connected with stock which urgently required investigation, but he knew of no country that was as healthy as Queensland, taking it all round. So far as the mere heat of the sun was concerned, it would be of interest to state that for three or four consecutive days he had experienced a temperature that measured as high as 118° F., but he had never heard of a single man or woman who had a headache from it, whereas if such temperatures occurred in Africa, where he lived for a number of years, he did not know how many corpses there would have been as the result. With regard to the question of the desert, not very long ago he had the honour of conducting Lord Bryce over a considerable portion of Queensland, and showing him some of the best agricultural and horticultural country, and Lord Bryce could hardly credit the statement when he assured him that there was no such thing as a desert in Queensland. The capabilities of that great continent were extraordinary. The Barkly Downs comprised a great area of country which was equal to anything he knew. It seemed to have a bed-rock of a sort of silicate limestone, which had been hollowed out here and there by the action of rainwater and the carbonic acid of the air dissolving out the lime, so that there were numerous great holes and cavities in the earth, into which the overflow of the rivers went to supply, probably to a very considerable extent, the water in the artesian

wells. There was as much water over that great area of the Barkly Downs as people liked to raise, and if the country were in the hands of the Chinese it would support at least four or five million people on the Barkly Downs alone. The country was so level that, although people could travel 120 to 130 miles a day on a motor-car, very often the horizon was bounded by the natural curve of the earth. As a result, the vegetation that grew and decayed was left on the spot; the country was so level that it was not washed away. The Flinders grass, which, in other parts of Queensland was about six or nine inches long, was 15 and 18 inches high along the Barkly Downs, and the Mitchell grass and the blue grass were growing in the finest profusion. The future of the country was certainly going to be enormous. One of the maps that had been shown gave an outline of the railways that were being laid down by the Government of Queensland to open up and develop the country. There were at the present time in Queensland between 600,000 and 700,000 horses, between 5,000,000 and 6,000,000 cattle, and about 22,000,000 sheep, and it was estimated that when the network of railways now in hand was completed those figures would be doubled.

The Hon. J. G. Jenkins (formerly Premier of South Australia), in seconding the motion, said that for a good many years he was Minister for the Northern Territory, and had the opportunity of presenting the finances of that Territory to the House in order to get them to vote a large deficit every year. He could fully endorse most of the remarks the author had made. It was often said that parts of Australia were a desert. He had been at Oodnadatta when it would have been impossible to find a blade of grass after searching over miles of country; but a few months later, after there had been two inches of rain, he had found grass a foot and eighteen inches high on the same ground. The man who had called the district a desert was there before the rain came; he should have gone after the rain, and then he would have corrected his statements. People had sometimes asked why the Arltunga goldfields in the MacDonnell ranges had not been further developed. As the Minister who had charge of the erection of the cyanide plant, he found that it cost from £28 to £30 per ton to cart the material from the head of the railway at Oodnadatta—which was 688 miles from Adelaide—for the 200 miles past the Alice Springs country. It would be easily appreciated that it was impossible to make mining pay if so much money had to be spent on the carting of the necessary material. Many of those present would remember Mr. Buchanan, of "Killarney," New South Wales, who was a very large landholder in both Western Australia and the Northern Territory. A few years ago Mr. Buchanan arranged with a Mr. Lewis to drive a thousand head of cattle right across the heart of Australia, from the Victoria River to Hergott Springs. Mr. Lewis carried out the work with a loss of less than thirty head of cattle, and animals that were worth £2 a head on the Victoria River brought £7 10s. to £8 a head at Hergott Springs when sold by auction. That showed the possibilities of the country so far as the cattle industry was concerned, and at the same time proved that Australia was not a desert.

The Chairman, before putting the resolution of thanks, said he desired to tell the audience a story which proved that all camels were not so reliable as those to which the author had referred. On one occasion a man with a camel came into Kalgoorlie from a distant spot in the interior. He met an old friend, who asked him to have a drink. He declined the invitation, but said that if his friend would give his camel a drink he did not mind. The ostler was thereupon told to give the camel a drink, for which £1 12s. had subsequently to be paid!

The resolution of thanks was then put and carried unanimously.

Mr. David Lindsay, after thanking the audience most heartily for the vote of thanks that had been accorded to him, said he would very much have liked, if time had permitted, to discuss more in detail the questions of the heat, natives and labour, that had been dealt with by Sir William MacGregor. Those three questions were so vitally bound up with the future of the Northern part of Australia that they were worthy of the study of the best scientific men. Personally he was born amongst the natives and lived amongst them; he knew them from one end of Australia to another, and therefore knew what he was talking about when he said that the West Australian native must not be compared with the Northern Territory native. Nor was it quite possible to compare the Queensland native with the Northern Territory native, who was a far higher being, much more intelligent, and capable of being made great use of. Native carpenters were employed in the building of the houses at Port Darwin, and he had seen a native go into a blacksmith's smithy, make a bolt, put a screw on it, make the nut, and everything requisite for the purpose. The natives also went into the forest, cut down the timber, brought it back, and erected houses with it. Such men ought not to be neglected and allowed to die out, but they would be so long as they were allowed to hang about the settlements. It was the so-called civilisation of the white man that was killing the native, and if the suggestion he had made, that was turned down so contemptuously, had been tried, even if it had cost Australia £25,000, it would have been nothing to the advantage gained by preserving probably 20,000 people who would be capable of supplying the labour necessary for the development of the north coast.

THE RIGHT HON. THE EARL OF KINTORE, G.C.M.G., writes:—I am greatly obliged to you for affording me the privilege of seeing a proof of the paper on "The Northern Territory of Australia" which Mr. David Lindsay is to read on Tuesday next. No living authority on that Territory, its needs and possibilities, is greater than the author's, and I am confident that his hearers will appreciate in some degree the exertion and hardships Mr. Lindsay underwent to possess himself of knowledge of which his paper is but a digest, and that they will be helped to realise the immensity of this great lone land, a land which, given railway communication, access to markets, water and labour, will be waiting for development and settlement. Up to now the Territory has never had a chance. Provisionally annexed to South Australia in 1864, it came later to be known as South Australia's white elephant. Herself sorely in need of population and capital, South Australia had nothing to spare for the huge territory annexed to her. What little she could do was done, but that the resulting benefit was small cannot surprise us, seeing that this dependency's development was in the hands of a Parliament sitting some 2,000 miles distant, and composed of members who were either wholly ignorant of, or largely antagonistic to, established and successful methods of development of sub-tropical countries elsewhere. Mr. Lindsay sets out the very promising prospect the Territory shows for horses, cattle, sheep, agriculture, and mining, and he points to the reasons why, so far, more has not been done. It only required a short visit to convince me of their accuracy. On my return to Adelaide, overland from Darwin, in 1891, I urged strongly that the Territory should be taken over by the Commonwealth Government so soon as it came into being, and that through railway communication between Darwin and Adelaide should be established. The Territory was taken over by the Commonwealth some four years ago, and it is satisfactory to know that active steps are being taken to bridge the gap of at least 1,000 miles between the existing railway termini. I remember how it was contended that this through route would materially shorten the time of transit for the oversea mails and passengers, but if through traffic is sought I much doubt whether it will be obtained if the gauge of the rails is not broad and the train-speed high. However, in any case this railway, and others which I am delighted to know are seriously projected, will do much to relieve the want of transport and the difficulty of access to markets. It is also most satisfactory to know that an energetic and competent mining department now exists to assist and encourage the mining industry, for it is a mere truism to say that the Territory's important mineral fields should support a population infinitely larger than 90 Europeans and some 500 Chinese! It is well established that the extensive alluvial areas on the rivers and coasts can grow sugar, rice, cotton, hemp, and other products, to support such a population; but until effective labour at rates which agriculture can afford to pay, and which Australia to-day cannot provide, can be found, I fear these valuable tracts will remain undeveloped. Perhaps something can be done with Latins from Spain or South America, as Mr. Lindsay suggests, but I more than doubt whether Australians of the temperate zones will ever be able to put in effective, continuous and remunerative work for their employers in the tropical climate of the Territory's coastal districts. Be that as it may, I cannot doubt that this difficult problem of labour must be solved by-and-bye, and the present drawback to agricultural development removed. Capital and population will follow, and the erstwhile white elephant of South Australia will come to be regarded as one of the most valued assets of the great Commonwealth, and its pioneers held in grateful remembrance. One last word. Among those pioneers, I hope, may be counted those who at Port Essington during the years from 1837 to 1849 endured much, and I trust steps may already have been taken for the due and reverent care of the ground where many officers and men are sleeping their last sleep. In my time the place was overrun with rank grasses and bush, while the lettering on the headstones was becoming overgrown and undecipherable. For the sake of the dead, and for their living descendants, we must all hope this neglect has been remedied. I greatly regret that absence from London will prevent me hearing Mr. Lindsay's paper, and from joining, by word of mouth, in the congratulations his Chairman, Sir George Reid, will receive on the occurrence of the anniversary of his birthday.

MR. LINDSAY writes:—The effect of working under the tropical conditions obtaining in the coastal districts of North Australia upon future generations is as yet unknown. No one can express a decided opinion. The second generation born there do not yet show any signs of degeneration, and when communication with the southern temperate regions is made easy and cheap, enabling the mothers and children to get away for occasional changes, I am sanguine of the future. I must confess I do not think that white men can retain their vigour, working in the sugar-cane fields and inhaling a miasmatic vapour, with a tropical sun blazing down on their backs. At present the domestic servant problem is an obstacle to white women settling and making permanent homes. I am much indebted to the Right Hon. Lord Kintore for his very appreciative letter and notes on my paper. The ideas expressed are those of one who has travelled right across the continent from north to south, and who spent some time on the coast. The expression of his views on the necessity for coloured labour caused considerable comment; but it was recognised that Lord Kintore's report was a valuable addition to the knowledge of the Northern Territory. Lord Kintore will be glad to know that the tombstones and memorials to the early settlers at Port Essington have been restored —I think by the generosity of someone in England.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 17th, 1915; David Milne Watson in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Hitchins, Alfred Bishop, 194, Main-street, Binghamton, New York, U.S.A.

Maxwell of Calderwood, Lady (Jane), Glen Owen, Cheltenham.

The following candidates were balloted for and duly elected Fellows of the Society:—

Misra, Gadadhar Prasad, 193/2, Harrison-road, Calcutta, India.

Park, Kendall, 50 Calle Ballester, San Gervasio, Barcelona, Spain.

The paper read was—

THE USES OF COAL GAS FOR INDUSTRIAL PURPOSES.

By H. M. Thornton, J.P., M.I.Mech.E.

In this historic lecture theatre, many of our scientists and scholars, and protagonists in the economic work and advances of this country, indeed of the world, have sent forth new messages and made new advocacy, and have contributed to the history of material progress.

Unlike some of those, I have to-night no new message to give you; but I have my story to tell—a story that has an interest not only for every industry in the work of which there is application of heat, but for every individual who has progress at heart, and whose desire is the improvement of our social conditions by the promotion of a more salutary atmospheric environment, and for every individual who sees in the suppression of waste and the substitution of economy fresh turns of the wheel of civilisation. The Royal Society of Arts has given a wealth of encouragement to all who have such stories to tell. Its records bear testimony to the work of those who have spent time in urging and fostering the improvement of the atmosphere of our towns and cities. A great deal has, from time to time, been said as to the existence of the insanitary conditions of that atmosphere. Computations have been frequently made by eminent authorities, guided by analyses of the air of towns—especially manufacturing ones—and by measurements of the soot and ash deposits, as to the degree of pollution that takes place under the local circumstances. We accept these computations without much question, because those of us who are of a less scientific turn of mind, but whose work is of that practical nature which is complementary to the work of the scientist, daily see the visible and outward signs—despite Acts of Parliament and the ordinance against the emission of "black" smoke. The important thing is to find an effective remedy, and in this direction I would express the hope that the Departmental Committee on Smoke Abatement (whose work has been interrupted by the war) will be able, through their report, to indicate practicable means for bringing about a material abatement, if not, as we hope, the complete abolition of the smoke curse, and so advance a much overdue reform in the daily conditions of town life.

Crude Heating Methods and the Destruction of Valuable Necessaries.

There are, to make a general division, two main sources of atmospheric pollution—the industrial chimney and the domestic chimney. With the latter I have not this evening anything to do. In the lectures delivered before your Society in the spring of 1913, Mr. F. W. Goodenough dealt with the domestic phase of the problem, and showed how heating for all domestic purposes could be obtained through the agency of gas—or, in some cases, coke—economically, without dust, without pollution, and with the maximum of efficiency. It is the industrial chimney with which we are concerned this evening, and the displacement of crude heating by a refinement which not only disestablishes the chimney as a polluter of the atmosphere, but introduces into the factory itself a controllable and uniform system of heating, producing constancy of result, and adding materially to industrial economy by the reduction of labour, the promotion of cleanliness, and the speeding-up and improvement of factory output.

These aspects of the case for industrial heating constitute the main part of my remarks this evening; but let me for a few minutes—without going largely into statistics—explain the great destruction of value for which crude methods of heating in our factories are responsible. Mr. Edward G. Hiller, in a paper on "Power Production in the United Kingdom," read before the Manchester Association of Engineers in January, 1914, supplied data showing approximately the quantity of coal consumed in the United Kingdom for various purposes during 1911; and it may be taken that they generally

agree with other calculations that have been made.

Factories	used 66	million tons
Householders	„ 84·3	„ „
Iron and steel industries	„ 32·1	„ „
Mines	„ 20·5	„ „
Gasworks	„ 15·4	„ „
Railways	„ 12·8	„ „
Potteries, etc.	„ 5·7	„ „
Coasting steamers	„ 2·4	„ „
Total	189·2	„ „

Now if we remove from this table only one item which bears upon the subject I have in hand this evening, we see that factories alone consume 66 million tons of coal a year, or just over one-third of the total.

What does this mean in the way of wastage? Supposing the 66 million tons of coal were carbonised in the retorts of our gasworks, and yielded an average of 12,500 cubic feet of gas per ton, we should have from it a total production of 825,000 million cubic feet of gas, which, on the new Parliamentary standard of 540 B.Th.U. per cubic foot, would be equal to 445 billion B.Th.U. It is impossible properly to grasp what such figures mean, but those billions of B.Th.U. are B.Th.U. that are in industrial heating controllable, and there is comparatively little waste in obtaining from them effective duty. With coal there is a large amount of waste of heat units in effecting its combustion, and in driving off those volatile constituents which are useless where high temperatures and pure incandescence are required, and must be obtained. There is also waste of heat units up the chimney shaft, and through stand-by requirements. There is waste of heat units every time a fire is re-charged until once more favourable working conditions of the fire are realised. With gaseous fuel—whether using high or low pressure, or low pressure with air-blast—the heat can be directed exactly as needed into the furnace or on to the crucible where required; and heat losses by radiation and otherwise can be largely prevented by proper construction and insulation.

Pursuing the point as to waste, we have our gas as the primary product. There are the secondary ones. First, there is coke. Carbonise the 66 million tons of coal in gas retorts, we should have for sale—deducting a reasonable amount for carbonising fuel—between 10 and 11 cwt. of coke per ton of coal, which would give a total of (say) 35 million tons of smokeless fuel for the market, with a calorific value of (say) 13,000 to 14,000 B.Th.U. per lb. = over 1,000 billion B.Th.U. in the aggregate. Then, according to the system of carbonisation, and the composition of the coal, we should produce some 10 to 11 gallons of tar per ton of coal carbonised; and so some 700 million gallons of tar would be realised. In addition to this, given good working—using a retort-carbonising system in which there is not a large destruction of ammonia, and with ordinary care in preventing waste of ammonia—there would be produced about 28 lbs. of sulphate of ammonia per ton of coal carbonised, or 825,000 tons of a valuable fertiliser.

These figures demonstrate the amount of waste that is taking place by such a large use of coal in our factories. I do not for one moment assert that the calculated data I have given would be realised from the whole of the classes of coal used in factories, but an equal weight of gas-making coals would give in valuable products approximately the returns which I have presented to you. Nor do I say that the whole of that coal could be displaced. But an exceedingly large part of it undoubtedly could be; and other industries of the country would be served by the provision of larger supplies of the materials to which I have referred that are required to meet, especially since the war began, the ever-expanding demands of our population and of the world.

Take tar, for instance. Apart from its value for the production of large quantities of oils of various grades, of beautiful aniline dyes, and of indispensable chemical products, its use has largely grown in recent years for road surfacing and road making. With the home extension of the aniline dye industry to supplant the huge German export of aniline dyes and colours to this country, tar, as the source from which the intermediate products are secured from which the dyes are made, will be required in considerably larger proportion. From tar, too, motor spirit (benzol) among much else is recovered. According to the quality of the coal used, the system of carbonisation employed, and whether the gas is washed for its recovery, from 1 to 3 gallons of benzol can be obtained from different coals per ton carbonised. The importance of the avoidance of the waste of the valuable necessaries resident in coal is accentuated by the war. Only recently the Army Council notified producers of tar that they require to have placed at their disposal all their production of toluol or substances containing it—such as commercial benzol, light oils, or solvent

naphtha—while interfering as little as possible with existing contracts. When it is remembered that 90 per cent. benzol produced from tar from Durham coal contains about 70 per cent. of benzene, 25 per cent. of toluene, the remainder being light hydrocarbons, etc., the importance of tar to the Committee on High Explosives and to the nation and its Allies at the present time (and for all time, for our protection and the satisfying of our wants) is self-evident. The toluene, I may add, is used for the making of trinitrotoluol: and as emphasising the waste that goes on, through the crude use of coal, the War Office are now making arrangements with our large gas undertakings for the washing of their gas for the extraction of the toluene from it. From the gas product of a ton of coal (say, 12,000 cubic feet), according to the coal used and the system of carbonisation employed, from 2 lbs. up to probably in cases 5 lbs. to 6 lbs. of pure toluene will be obtained. Assuming only 2 lbs., this amount will make 4 lbs. of trinitrotoluol. (*Journal of Gas Lighting*, February 16th and 23rd.)

Dawn of a New Era in Industrial Heating.

I have thus far trespassed upon your patience n showing that, in addition to air pollution, industry is largely wasting, by its crude methods of heating, parts of the substance of the country which are necessary—more necessary to-day than they have hitherto been, though always valuable since their discovery. I believe I have successfully shown that, for economic reasons, the coal cast under the boilers of the factory or stoked into the heating furnaces, results in a wastage wholly appalling. The question naturally arises: Is it practically possible to do away with the waste? Admittedly custom in industry is a difficult thing to eradicate. Manufacturers, however, are beginning to look upon these matters from a more enlightened point of view than of old. In the mechanical handling in our industrial works, science has long since won way; but it has made made way at slower rate in regard to the heating operations, whether it be for melting, annealing, hardening, or otherwise. Experience of the new methods—experience satisfactory in every way—is also having weight. In fact, much has already been done in supplanting crude methods of heating by the refinement of gas processes; but that much, my intimate knowledge of possibilities permits me to say, represents only the dawn of a new era in industrial heating.

The Manufacturer's Point of View.

The manufacturer has his point of view in this matter; and we have to adopt, in order to secure his examination of the question from other points of view, the art of "gentle persuasion," though not the "gentle persuasion" practised by the man on strike. So far we have considered the benefit to the community; but here, as in arguing the case for coal smoke abatement, it is necessary to show to the manufacturer that it is not only to the benefit of the community, but to his direct benefit as a manufacturer, to adopt the modern smokeless method of firing. Some of the advantages are:—

(1) Economy in space occupied by appliance; necessity, and expense in some cases, of smoke-stack eliminated; a practically unlimited choice of position for the furnace, which enables it to be brought into close proximity to the machine workers.

(2) No space required for storage of fuel, and no removal of ashes.

(3) Increase in output per cubic foot of factory, owing to economy of space occupied by gas-furnaces in comparison with hard-fuel furnaces.

(4) The constant and unvarying supply of fuel of a uniform calorific value, at a fixed rate.

(5) Labour saving—absence of stoking, storage and conveyance of fuel.

(6) Rapidity and improved production, due to ability precisely to control correct working temperatures.

(7) In many cases a lower capital expenditure of installation.

(8) Cleanliness, which frequently is of primary importance where furnaces have to be introduced into machine-shops, or in close proximity to machines.

As a concrete example of the foregoing advantages, I would like to quote the experience of a large firm of spring-makers. They recently installed seven gas-furnaces in substitution for hard-fuel furnaces, and their testimony is highly interesting. Summarising it:—

(1) They save two-thirds of their floor space.

(2) They save labour to the extent of dispensing with one stoker

(3) They secure absolute reliability and uniformity of temperature, which is highly essential in spring-making.

(4) They entirely eliminate smoke and soot in their workshops.

(5) Their fuel bill for coal-fired furnaces was for one year £694; the gas consumption for executing the same work was the next year

£425—showing a saving in fuel alone of £269 per annum.

In view of these advantages, it is not surprising to learn that this firm decided to abandon solid fuel entirely; and they now do the whole of their work with gas-furnaces—their consumption of gas being nearly 8 million cubic feet per annum.

As another example, the following figures, obtained from a firm manufacturing chronometers and nautical instruments, are highly convincing:—

(1) They previously used steam for power, and coke for brass and gun-metal melting furnaces, at a cost of £135 per annum for fuel.

(2) They now use a gas-engine and gas crucible furnaces; and their gas bill is £105 per annum, showing a clear saving of £30 per annum.

(3) In addition to this, they now secure an average number of six melts per day, as against four with coke-furnaces; and therefore, supplementing a saving of 22 per cent., they have increased their output by 50 per cent.

Having briefly enumerated the national advantages to be obtained by the use of gas for industrial purposes, and also shown how the manufacturer himself may benefit, I will now, by illustration and brief description, show what an important part gas is already playing in the advancement of some of our largest industries, which gives us encouragement to hope that the ideals expressed in the commencement of this paper may one day be realised.

DEPOSING THE COAL-FIRED STEAM-BOILER.

Our attention must be first directed to the primary requirement of most manufacturing establishments, viz., the creation of power. The old coal-fired steam-boiler still exists in numerous factories; but steadily the gas-engine is superseding it wherever its application is possible. Fig. 1 shows part of the engine-rooms of the Richmond Gas Stove and Meter Co., Ltd., at Warrington. The power for these works, which employ over 1,000 men, is entirely obtained by gas, amounting approximately to 500 h.p.

FIG. 1.—PART OF ENGINE-ROOMS OF THE RICHMOND GAS STOVE AND METER COMPANY, LIMITED, WARRINGTON.

In some factories where power is used intermittently, electric motors applied to each individual machine are found more convenient than driving by shafting from a central power source. In such cases gas-engines are very frequently and advantageously employed for the generating of the current required. Fig. 2 shows a very large installation of 2,700 b.h.p. gas-engines for generating electricity at the Crystal Palace.

The Bonecourt gas-boiler provides means for steam-raising, and for this purpose is being increasingly used.

I have, with brevity, shown that the first essential for a works requiring power can be provided by gas, whether by means of gas-engines or by the process of steam-raising, also by means of gas. Having established this point, and before passing on to review the numerous furnace applications for town gas, I should like briefly to mention also the very extended field offered for the use of gas coke for heating large muffle or oven furnaces. As before stated, this great by-product of carbonisation in gas-making, offers an excellent smokeless fuel, which Continental manufacturers use much more freely than we do. When it is used in a modern furnace we are indeed employing this coke to produce our desired gaseous fuel and thereby following the dictates of efficiency, of economy, and cleanliness.

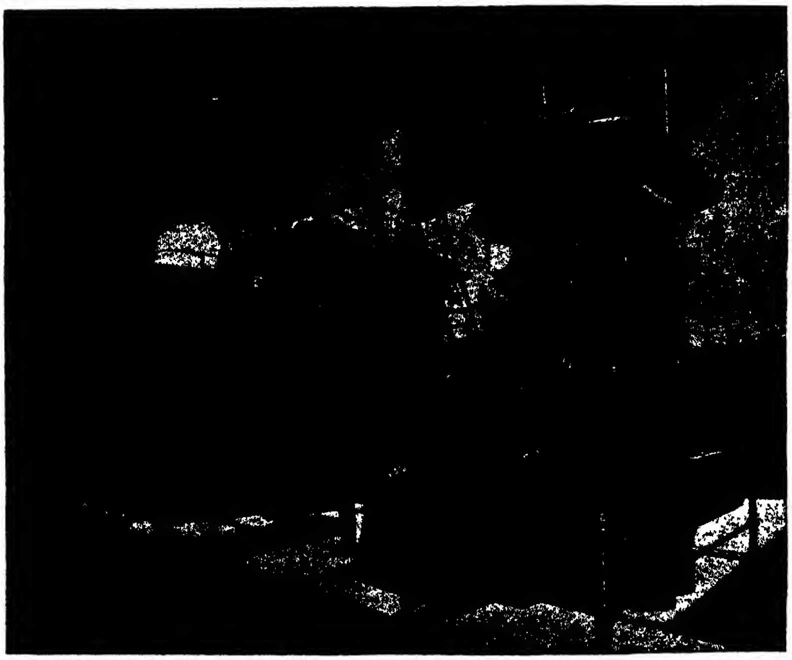

FIG. 2.—2,700 B.H.P. GAS-ENGINES FOR GENERATING ELECTRICITY AT THE CRYSTAL PALACE.

REPRESENTATIVE FURNACES.

In the first place, it will, I think, be interesting to describe briefly some of the chief points of the principal types of furnaces.

From the Laboratory to the Works.

Gas-heated muffle and crucible furnaces, and so forth, are not new. They have been used in the laboratory for experimental purposes for many years. But those laboratory appliances did not take count of the relation of fuel consumption and of time expenditure to work done, as is necessary in industrial operation. The most that was required of them was the attainment of given temperatures for special work. To translate the old laboratory furnace and crucible equipment to the needs of the factory and large-scale working was not a mere question of rule-of-thumb or proportion. It has meant hard, persistent investigation under the different conditions and requirements of service. Without going into the difficulties at first encountered, and technicalities which would be irrelevant to the general purpose of this paper, it is now a fact that positive success has been attained in the application of town gas as a fuel for large furnaces in ordnance works, and a whole range of furnace requirements down to the smallest crucible furnace for gold-melting.

The oven or semi-muffle furnaces have the most extended application of any gas-furnaces. They are required by almost all manufacturing firms in one form or another for the various kinds of annealing, reheating, case-hardening, and hardening. These different operations require different heats. Light or heavy work will determine whether the furnace should be of medium or maximum strength in structure; while in each case the heat generated must be

FIG. 3.—NATURAL DRAUGHT GENERATOR OVEN FURNACE.

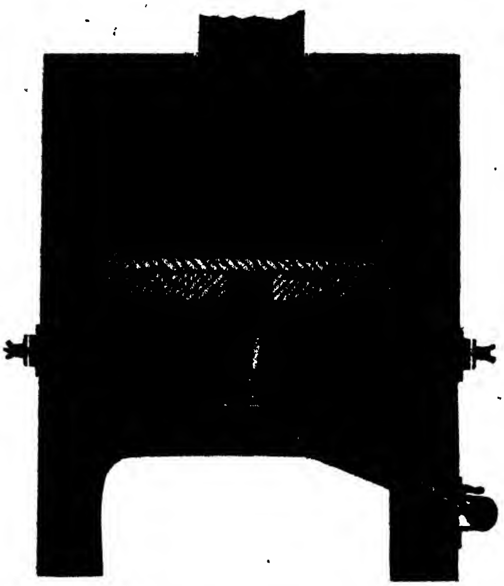

FIG. 4.—SECTION OF NATURAL DRAUGHT GENERATOR OVEN FURNACE.

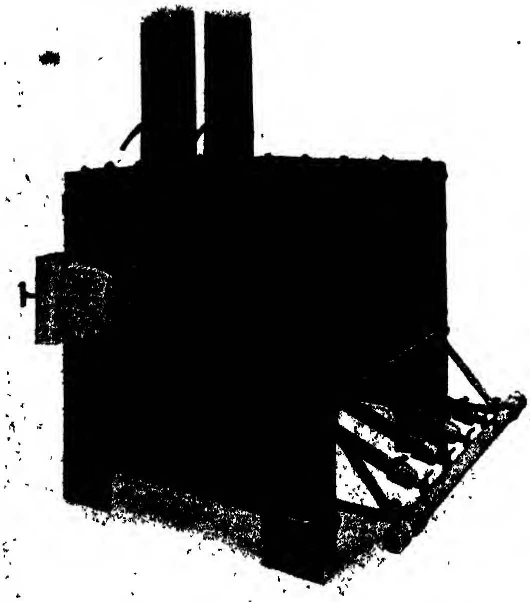

FIG. 5.—NATURAL DRAUGHT REVERBERATORY FURNACE.

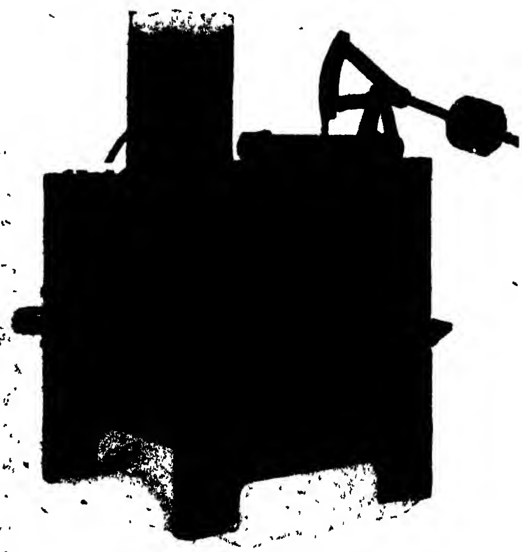

FIG. 6.—LOW-PRESSURE GAS AND AIR FURNACE.

TYPES OF GAS FURNACES (RICHMOND'S PATENT).

produced under the most economical conditions commensurate with uniform or even heating. These varying conditions have given rise to three distinct types of furnaces, each having a wide field of usefulness, viz. :—

(1) Natural draught generator oven furnace, suitable for annealing, reheating, hardening, and light case-hardening.

(2) Natural draught reverberatory oven furnace, suitable for annealing heavier work and case-hardening.

(3) Low-pressure gas and air oven or chamber furnace, suitable for annealing, reheating, hardening both high speed and carbon steel, case-hardening, forging, both heavy and light work.

Each of the two first-named furnaces has its own particular field of usefulness, while the third has such a wide range of temperatures—viz., up to 1,400° C.—that it has practically universal application.

(a) Natural Draught Generator Oven Furnace.

Illustrations 3 and 4 show this furnace and a cross-section. Special high-power bunsen burners are employed; the burner mouths being sealed from the air at the point of entrance to the combustion chamber. Primary air is admitted to the burner in reduced proportion; while combustion is supported by preheated air entering the combustion-chamber by a series of lateral air nostrils—these being heated by radiation from the floor bricks of the furnace. This furnace is very efficient, and particularly adapted to the lighter class of work—for example, the thermo treatment of motor gears, which itself represents a very large industry, the hardening of machine and other tools and parts made from carbon steels, the annealing of those parts, etc. The manipulation of this furnace is quite simple. Should a reducing atmosphere be desired for the thermo treatment of gears, etc., under non-scaling conditions, it is simply a question of reducing the air-inlets; whereas for higher temperatures the air-ports are left open. This furnace has been, and is to-day, a most satisfactory type for the work above described.

(b) Natural Draught Reverberatory Furnace.

Illustration 5 shows this furnace. Like its precursor, the generator furnace, it is on the natural-draught principle, and requires no mechanical plant for air compression. It is heated on the reverberatory idea—that is to say, the gas enters the furnace chamber, and pre-heated air runs along the furnace bottom through fire-clay nostrils, which meets burners at the points where combustion takes place. The flame then passes along the underside of the furnace-chamber roof, and downwards under the floor of the furnace chamber before entering the flues underneath, which find their exit up the side of the furnace wall. The furnace-floors are strongly supported—in fact, they may

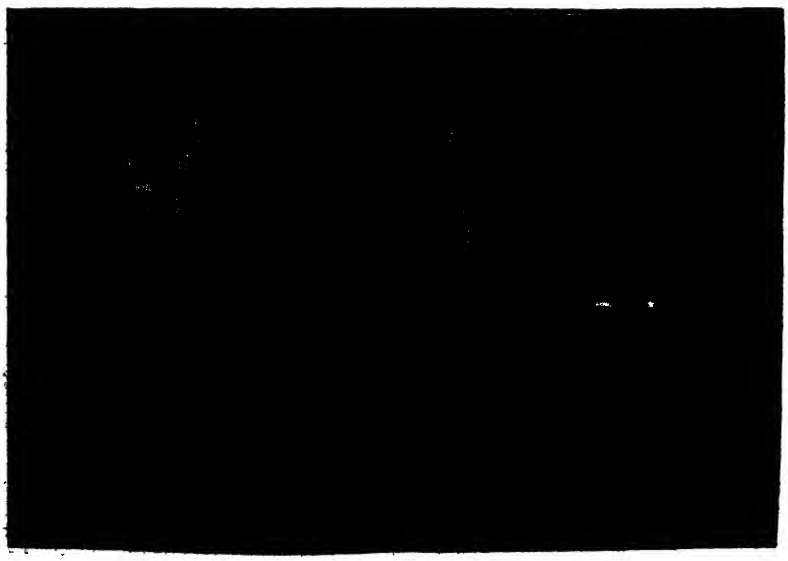

FIG. 7.—TWIN OVEN FURNACES FOR ANNEALING METAL STAMPINGS. Soft Metal Melting Furnaces also seen on right-hand side.

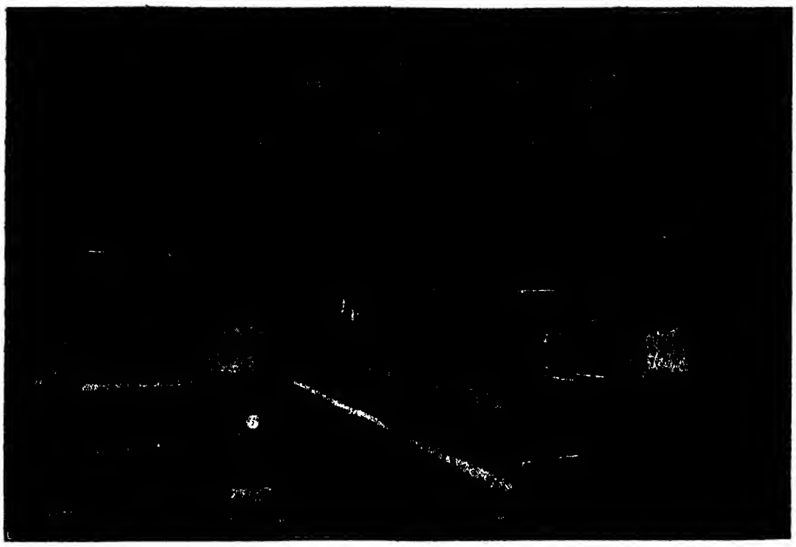

FIG. 8.—TWO 16-FT. STEEL BAR ANNEALING FURNACES OF REGENERATIVE TYPE.

be made to any reasonable thickness to suit the heavier class of work, such as carburising in boxes, annealing steel in bulk, normalising steel casting, etc. It will be noticed that this furnace has no combustion chamber other than the working chamber itself. Working results obtained from one of the largest factories in the kingdom prove this design of furnace to be of practical value, and a great success for the heavier class of work where heats up to 950° C. or 1,000° C. are employed, and no air blast is available.

(c) *Low-pressure Gas and Air Furnace.*

Fig. 6 shows this furnace. The principle involved is entirely new. Air at approximately 2 ins. water-gauge enters the firebrick lining at the roof of the furnace through a series of fireclay tubes from the main air supply. The air thus travels down the side, and along the bottom of the furnace, is preheated, meeting the incoming gas at the point where combustion takes place. The products of combustion then pass along the underside of the furnace roof, and downwards under the floor, as in the case of the reverberatory

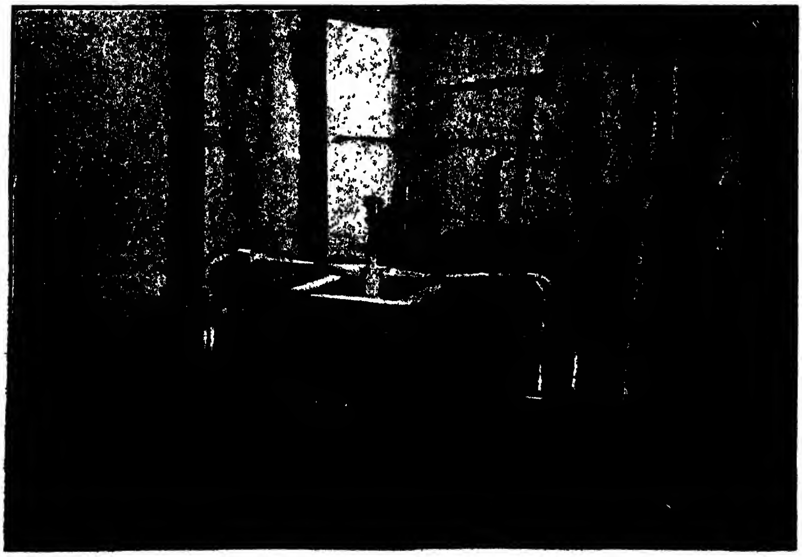

FIG. 9.—WELDING OF BAYONET HANDLES TO BLADES.

furnace. An oxidising or reducing atmosphere is obtained by increasing or diminishing the air pressure. Like the reverberatory furnace, it is of exceptionally strong construction; but it has advantages over the former, inasmuch as it covers a wider range of work—temperatures up to 1400° C. being obtainable. This furnace is suitable for all the operations before mentioned, besides which it can be usefully employed for the baking of emery wheels, firing of porcelain (with muffle), heat treatment of tungsten ores, heating up blanks for drop forgings. Generally speaking this furnace covers the widest number of working conditions, and has the advantage of being the most economical and efficient for the operations referred to. For annealing steel bar it supersedes the generator type of furnace, because it is possible to anneal under the most perfect conditions. In other words, the cooling process in steel annealing, which is spread over something like eighteen hours, may be achieved with this furnace, free from any possibility of cold air finding its way into the furnace chamber, and thus causing scale on the work, which, of course, is detrimental.

FIG. 10.—PART OF THE HARDENING SHOP OF AN IMPORTANT MOTOR AND ENGINEERING WORKS.

TYPICAL INDUSTRIAL APPLICATIONS.

To enter into a detailed description of the numerous industrial operations for which gas is, can, and will be used, or to give anything but very general particulars, would be an impossible task; but to give a brief review of its uses in some of our leading trades, I think, will be of interest to you.

ANNEALING.

For the annealing of stampings made from sheet-metal, gas is being increasingly used; and where the metal stampings are subjected to one or two heats only, a single oven furnace serves the purpose. Some stampings have to be subjected to the pressing or drawing machine four or five times or more, and require annealing between each operation. This is often the case with special forms of stamped or drawn nickel-silver, brass, etc. For this purpose a twin oven furnace is preferable; the top oven being used for preheating the articles gently before subjecting them to the full annealing temperature in the lower oven—thereby avoiding heat-cracking, which may take place when the single oven type is used. Fig. 7 clearly shows the working of this apparatus.

Wire manufacturers in some cases use gas-furnaces for annealing the finer grades of wire. At Cleckheaton (Yorkshire), the wire industry is responsible for a large portion of the 45 million cubic feet of town gas consumed per annum for industrial purposes. The heavier grades of wire

are usually annealed by hard fuel; but even at the present time gas-jets are employed at the entrance to the heated chamber to prevent the admission of air, and consequent scaling of the wire.

Fig. 11.—Gas-oven Furnaces for Tempering and Colouring Cartridge Clips.

Gas-furnaces can also be employed for annealing steel tubes, also for softening the ends of steel studs used in the motor and cycle chain-making industry. Steel pens, gun barrels and breeches, motor cylinders prior to repairing by the oxy-acetylene process, and many other articles are also annealed by gas.

Manufactured steel, in bars, is sent out by the makers in an annealed condition; and for this purpose gas-furnaces are being increasingly used. Fig. 8 illustrates two steel bar annealing furnaces. These are approximately 16 ft. long, from which fact it will be obvious they consume gas on a fairly large scale. Annealing in coal-furnaces necessitates packing the bars in a heavy cast-iron box to prevent scaling of the steel. This box is considered by some to be unnecessary in the gas-furnace, in view of the uniform conditions under which gas-furnaces work. The elimination of the box naturally means less absorption of heat. Decreased labour is also an important factor—in short, gas annealing has been proved very economical. In many of the smaller steel works where annealing is intermittent, the saving achieved by the use of gas-furnaces is something like 50 per cent. in the cost of fuel alone—a fact in works' economy which cannot be ignored by the manufacturer in these days of keen competition.

The following are figures obtained from actual working:—

Annealing Steel in Richmond Regenerative Gas Oven Furnace.

	Carbon Steel.	High-speed Steel.
Weight of charge	35 cwt.	45 cwt.
Total time of heating	6 hours	9 hours
Time of cooling	42 "	40 "
Total time of operation	48 "	49 "
Maximum temperature attained	880° C.	875° C.
Gas consumption per ton of steel	3600 cubic feet	5000 cubic feet
Cost of gas per ton of steel annealed with gas at 1s. 6d. per 1,000	5s. 5d.	7s. 6d.

Succeeding Operations.

Following the progress of the steel bar to the manufacturer of hand and machine tools, gear-parts, mining and agricultural implements, cutlery, ordnance materials, electrical appliances and the manifold component parts of machinery, we come to the processes of hardening, case-hardening, and tempering.

Hardening.

This process, as you will be aware, is the one whereby steel is converted into its hardest state by being subjected to heat and quickly quenched off to a cold temperature, either by means of liquid, or by air blast.

Case-Hardening.

This is the method of converting mild steel, which will not harden direct, into a steel which will harden glass-hard on the surface when quenched off in water, leaving a soft core in the centre of the bar; making practically an almost unbreakable steel. This steel is, for example, very suitable for gear wheels, cam shafts, bicycle and motor parts. After the carburising process is complete, the steel article is subjected to a hardening process, which varies according to the different methods in vogue, and is generally known as the "thermo treatment" of steel. For all these operations gas-oven furnaces are being increasingly used.

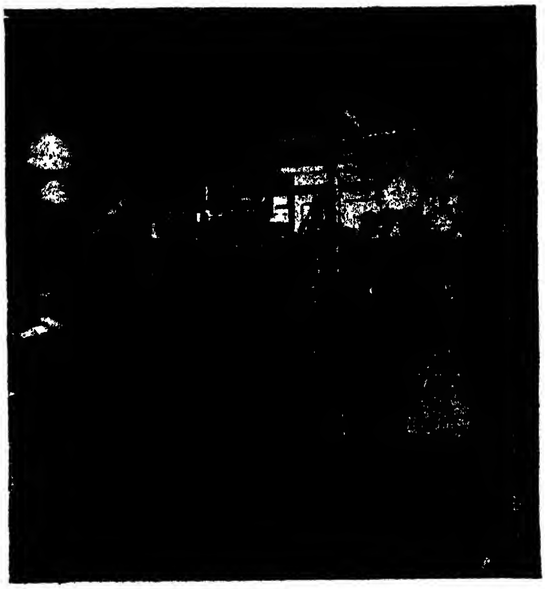

Fig. 12.

Lead-melting Furnaces at "Lloyd's Newspaper."

Tempering.

Here we have the process of heating up hand and machine tools, gearings, etc., to the temperature which is known to give the temper to the steel. The operation is carried out by two

Fig. 13.—Part of one of the Laboratories of the Imperial College of Science and Technology, South Kensington, showing a Suite of Assaying Muffles.

different methods—*i.e.*, tempering by colour, or by temperature. Such articles as razors, shear blades, saws, and articles of a kindred nature are frequently tempered by colour on an open or covered heating plate. Tempering by colour of smaller articles is more generally executed in rotary furnaces—*e.g.*, the tempering of motor and cycle chain links.

Messrs. Gillott, of Birmingham, use a rotary furnace for tempering steel pens.

Tempering by temperature without colour is done in furnaces containing oil, fat, lead, or salt mixtures.

The various and complex methods of the thermo treatment of steel to which I have referred in necessarily (owing to time) a somewhat cursory manner, and which differ according to the qualities of steel and methods adopted, illustrate the wide field of usefulness for town gas in all hardening shops—in fact, wherever manufactured steel is used.

Gas and the Production of Munitions of War.

At this critical time in our national history, those of us engaged in the gas industry are naturally highly gratified at the wide extent to which gas is used in the production of our armament and ammunition, in factories, in shipyards, and in Government works. It would hardly be too sweeping an assertion to state that all the requirements of our Army and Navy are under tribute to gas in some way or another.

For instance, the heat-treatment of shells—a matter of vital interest to our national existence at the present moment—is largely carried out by the use of gas furnaces; and the extension of their use in this direction is almost a matter of daily occurrence. Some of these furnaces are comparatively small; but even the largest shells are to-day being treated in this country in gas-furnaces. One furnace recently supplied to an armament firm holds at one charge eleven of the largest naval armour-piercing shells—each shell weighing over one ton. Owing to its size, this furnace had to be dispatched in sections to the works where it is in operation; and therefore could not be photographed.

Oven furnaces, similar to those I have previously described, are used for annealing component parts of revolvers.

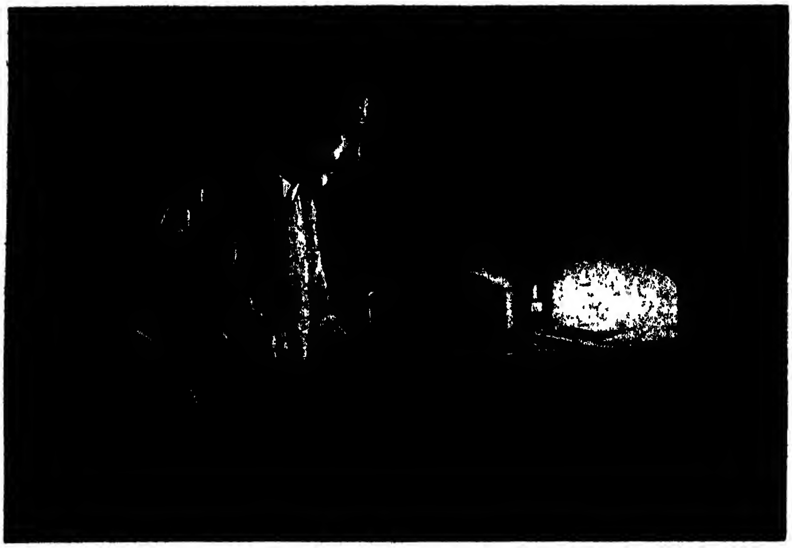

Fig. 14.—Firing Enamels on Jewellery, etc., in Muffle Furnace.

A further instance of the national value of gas during the last eight months in fitting out our new Army is seen in Fig. 9, which shows the heating equipment used in the welding of bayonet handles to their blades.

Fig. 10 illustrates part of the hardening shop of an important motor and engineering works associated with a famous armament company. You will notice here that all the furnaces use gas as fuel; and, since the war started, additional ones have been installed, greatly assisting the output of gear parts, etc., for transport and other vehicles. There are also quite a considerable number of manufacturers who, finding the demand for their usual commodities

considerably lessened, if not entirely, though temporarily, wiped out, have been enterprising enough to adapt themselves to the special demands of the present time, and have had their energy and perspicacity amply rewarded. This conversion of old, and the initiation of new industries have been going on in this country to a larger extent than is generally known; and in these changes is one more tribute to the genius and energy of the British manufacturer. To the availability of gas, and its elasticity in application, is due the possibility of making these developments, and of making them so promptly and rapidly. Any number of gas-fired furnaces for any kind of heat treatment can be installed; the gas and (if necessary) the air-blast can be connected in almost a few hours; and the new class of work can be inaugurated at once. To give only one example, a company manufacturing musical instruments found the public demand in war time somewhat lessened. The illustration (Fig. 11) will show you gas-furnaces that were ordered and installed in a few days; and the same shop which produced the former has been transformed into a highly important adjunct to our Army supplies. The operation, you will observe, is the tempering and colouring of the small steel cartridge clips; each furnace dealing with about 10,000 clips per day.

Another specific instance of how gas has served us during war time is in our air-craft factories, where gas-furnaces are used continuously both in the Government and private works which are unceasingly active day and night to enable the country to maintain its supremacy in the air. Unfortunately (perhaps otherwise), I have not been allowed to photograph any of the air-craft factories where gas-furnaces are in use.

The Heat-Treatment of Metallic Ores.

This is an industry which has hitherto been largely developed in Germany, and since the outbreak of war the manufacture has been energetically taken up in this country. These ores which form alloys for special steels are heat-treated in high temperature gas-heated oven furnaces, and roasted at lower temperatures in a similar type of oven.

Metal-Melting.

Let us consider for a few moments the subject of metal-melting. The applications of gas for metal-melting are particularly varied. It is used by gold refiners, jewellery manufacturers, goldsmiths and silversmiths—in fact, wherever precious metal is melted from its solid state for any manufactured process, gas is found to be the most satisfactory fuel.

The melting of brass, aluminium, admiralty, and other alloy metals also present an important opening for the application of gas-heated crucible furnaces.

Lead and metal melting is found in many industries. One of the chief and most familiar

Fig. 15.

Steam Generators for Heating Printers' Presses.

trades to which gas for lead melting can be applied is the printing trade. In every town—metropolitan or provincial—the printing trade is represented in some form or other. The type-founder who supplies the type for the printer requires a lead-melting furnace for type-founding, the stereotyper for stereotyping, and the general melting of metal for composing machines, which is a daily process in large printing offices. Fig. 12 shows Lloyd's newspaper type-foundry with lead-melting furnaces. One could continue enumerating the applications

of gas for melting metals; but enough has been said to show the extensive possibilities for this purpose.

An "internal" heater, suitable for melting soft metal, boiling liquids, etc., has recently been introduced. This "internal" heater is immersed in the metal or liquid; and therefore the heat utilised is greater than if the burners are placed beneath the tank in the ordinary way.

One particular operation for which this is being used is the heating of vats containing 200 gallons of cold water. Into these, bones are placed and steeped for about four hours, after which the gas is lit; and the hot water cleanses the bones and extracts the marrow. The method previously employed was the injection of steam into the vats; and owing to these being constructed of wood, any ordinary method of gas-heating would have been difficult. The invention, however, of this "internal" heater solves the problem; and it is performing the work very satisfactorily.

Varnish Making.

Gas-boilers for the making of varnish are being rapidly installed in preference to coal-fired boilers, and have proved to be quicker and cheaper for an equivalent amount of work.

The results in one instance were as follows:—

With coal-firing, the time taken was six hours, and a coal consumption of 2¼ cwt. at a cost of 1*s.* 4½*d.*

With gas-firing, the time taken was two and a half hours, and with a high-power burner consuming 150 cubic feet per hour, the total consumption was 375 cubic feet. The approximate expenditure was about 8½*d.*, free of all labour cost, with the advantage of an increased production and absolute safety from fire, which is a vital factor in the manufacture of varnishes.

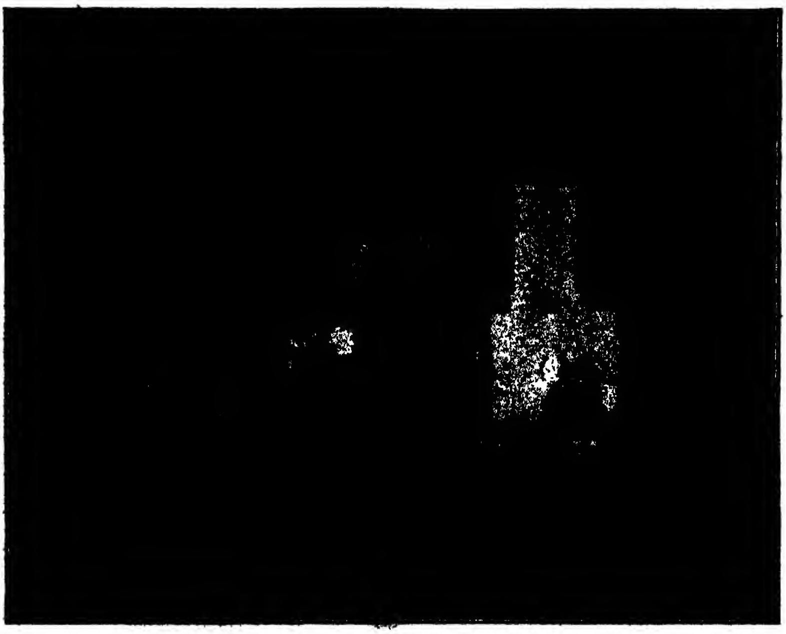

Fig. 16.—"Glory Hole" Furnaces for Heating and Re-heating of Glassware during Formation and Finishing.

Brazing, Blow-Pipe, and Soldering Work.

For brazing, blow-pipes with gas and air-blast or high-pressure gas are extensively used. Marine engine works and copper tube works have been brazing heavy flanges on copper pipes with hard-fuel brazing furnaces; but quite recently some of them have been persuaded to use gas for this purpose. In this case, the advantage as compared with the hard-fuel system is that the metal and flux are kept clean and free from particles of dust, and, therefore, a more reliable joint is made.

Recently a new brazing method came to my notice. An engineer associated with the Indian railways has introduced a new brazing material in connection with which he advocates the use

of town gas. Heavy castings, such as large cog-wheels and embossing presses, which have been fractured, have been successfully repaired with his brazing material by the use of gas blow-pipes. Blow-pipe work has many applications other than brazing. For instance, electric lamp bulbs are sealed by gas.

Another electrical firm consumes gas freely for industrial purposes, using gas-fed soldering irons in the manufacture of armatures.

A large factory in the east end of London, which produces about 14 million tins per annum, and is at present engaged on a large Army contract for tins to contain rations and biscuits, uses about fifty gas-heated soldering-iron stoves. In addition to this, these manufacturers use several gas-heated machines for the spreading of rubber rings to make joints for "decorative work"—*i.e.*, tins with enamelled exteriors to contain liquids, such as paint, foodstuffs, etc.

FIG. 17.—THREAD-SINGEING MACHINE FOR REMOVING SINGLE THREADS OR STRANDS.

ASSAYING.

In all metallurgical laboratories, public and private, chemical laboratories, research departments of public companies, and also by analytical chemists, we find useful work for gas. Fig. 13 shows one of the laboratories of the Imperial College of Science and Technology, South Kensington, fitted with fifteen muffle furnaces, which are employed for the assaying of metals by the mining engineer students.

The Metallurgical Laboratory of the Birmingham Municipal Technical Schools is also fitted with gas muffle furnaces.

In the assaying laboratory of the Heriot-Watt College, Edinburgh, which is one of the best equipped institutions in the country, there have been installed gas furnaces for experimental and demonstration work.

ENAMELLING.

In the art of enamelling on metal, china, and pottery, and gilding on glassware, gas is being used most successfully. The famous Ruskin pottery, for some of its finer productions, is fired in gas-heated furnaces. Fig. 14 shows the process of jewellery enamelling; and the same kind of muffle can be used for all kinds of enamelling on metal.

JAPANNING.

As a few examples of the very extended use of japanning ovens, I might mention the cycle, bedstead, gas-stove, fire-grate, electrical, tin-ware, brass hollow-ware trades, as well as many others.

Steam.

We now turn to the raising of steam by gas; and the next illustration (Fig. 15) shows the gas-steam generators for heating printing-presses.

Steam is also required in the bending and shaping of cardboard, wood, umbrella-handles, walking-sticks, and many other similar articles. Gas is used, and could be universally and economically employed in all these processes.

Glassware Industries.

Quite recently there has been a distinctly forward movement in the adoption of gas for the different heating operations in the manufacture of glassware, and the further growth of this trade, owing to the war and cessation of supplies from Germany and Austria, will be considerably advanced by the aid of gas. During the operation of glass-blowing, the glass under process of formation requires re-heating to maintain it in a plastic condition. For this purpose gas-furnaces, called by the trade "glory holes," are now being used. These furnaces are also used for obtaining a good finished surface on moulded glassware. Fig. 16 shows two in operation. As soon as the glass-blower has finished his work on the article, it is immediately transferred, while hot, to a low-temperature furnace to allow gradual cooling. In some of the modern glassworks the furnace for cooling down is of the Lehr type. These furnaces are usually from 40 to 70 ft. long, and about one-fourth of the length is heated by town gas to a scarcely visible red temperature. The hot gases from this portion of the furnace travel through the remaining length, thus giving a graduated heat. The articles are placed in the warm end of the furnace and travel down very slowly towards the cool end, carried on rectangular iron trays, which are attached one to another. These trays are drawn along by a hand-winch with ratchet 2 ft. every thirty to sixty minutes, according to the class of work.

In the stained-glass trade, gas kilns for firing glass are used. The colours are painted on the glass, the glass is placed on a trolley, and is wheeled into the kilns, the firing taking from thirty to sixty minutes.

Fig. 18.—Cloth-singeing Machine for removing Nap and Loose Threads.

Sugar-Melting.

Considerably over 350,000 tons of sugar are melted annually in this country for the production of jam and confectionery, and gas is coming to the front in this direction, and results can be obtained with it that should ensure a much more general use for the numerous smaller sweet factories and trades, which may be found in almost any town.

Cotton.

We are well aware how much we rely for our prosperity upon the cotton and woollen industries; Lancashire and Yorkshire between them supplying the whole world with their manufactures in some form or another.

Fig. 17 shows how gas is used for the purpose of thread-singeing. The thread is automatically

wound off a bobbin, and passed through a naked gas flame on to another bobbin at the rate of 200 yards per minute; the single threads or strands being burnt off (singed) in the process.

Since the introduction of the present gas method, the improvement in the quality of the material, and in other directions, has been considerable. A machine (as shown) will use about 300 cubic feet of gas per hour; and it will, therefore, be understood how great is the consumption of gas throughout the County Palatine for this one industry alone.

bleaching or scouring. The machine is made specially for use with gas by the largest manufacturer of textile machinery. The consumption varies according to the quality of cloth and the number of gas burners used; but a single-burner machine, with ordinary width cloth, consumes from 200 to 250 cubic feet per hour.

Tentering is the stretching of the cloth. To enable this work to be carried out more effectively, the cloth is first moistened by being passed through or over a steaming-chamber or damping-box. It is then clipped at each side,

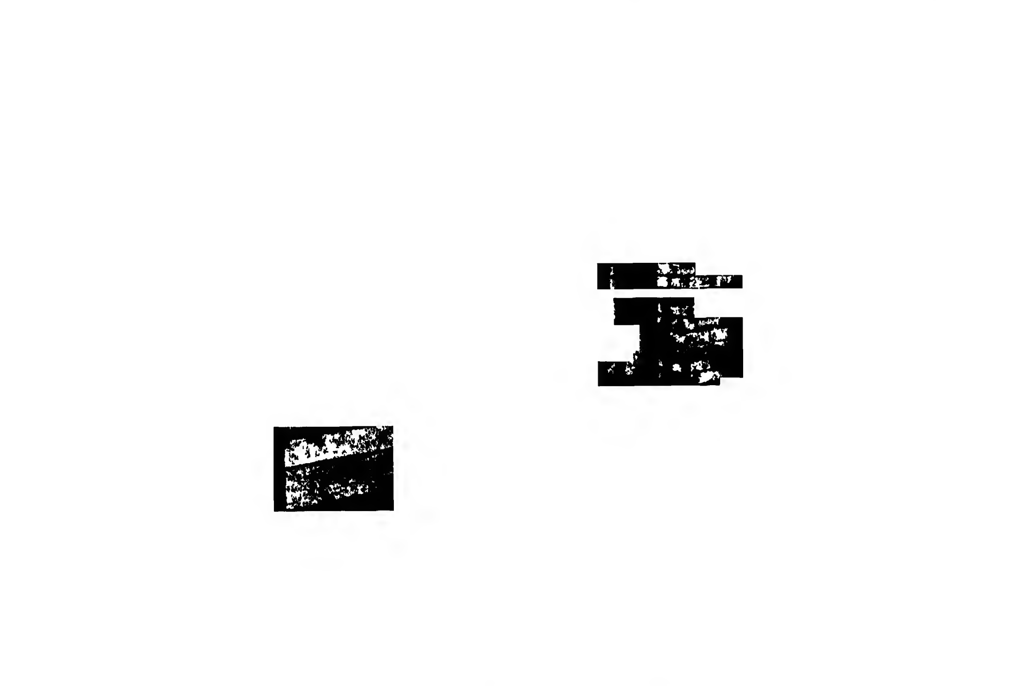

FIG. 19.—MAKING PEAK CAPS FOR HIS MAJESTY'S FORCES.

CLOTH INDUSTRY.

Fig. 18 gives some idea of the gas appliances used in the cloth industry. Here we see the material being singed. This process consists in burning off all the nap and loose threads from the cloth. It is the first stage in the preparation of the cloth for bleaching, dyeing, printing, and finishing; and in this way the surface of the cloth is prepared for the various finishes which it is desired to obtain, and made suitable for being printed upon. The cloth is passed over gas burners at a speed varying from 80 to 200 yards per minute, according to the class of goods being treated. It is then run through water to extinguish sparks, and is left in the wet state until it undergoes the subsequent operations of

stretched, and passed through the machine at an average speed of 40 yards per minute. In its passage through the machine, it passes over gas flames, above which is placed a copper sheet, which, when heated by the gas, drives the steam and moisture out of the cloth.

HAT TRADE.

In the making of felt and silk hats, gas can be used from start to finish—shellac for stiffening, pressing for shaping, burners for singeing, irons for velouring.

Referring again to military requirements at the present time, we have in Fig. 19 an illustration of a large London factory, which is turning out daily 4,500 peak caps for our soldiers. On

the right-hand side will be seen a battery of thirty-six irons heated by gas, while the steam blocks on which the caps are shaped are also heated underneath by means of bunsen gas-burners.

Boot Trade.

The boot trade is dependent upon gas in several of its processes. Specially designed gas-heated apparatus is used at the Shurephit Shoe Factory for drying the cement used for "blocking" the toe-caps of boots.

It is a circular table, in the centre of which is a metal chamber heated by gas. In this, holes are cut to allow the toe-caps of the boots to enter in order that the cement may be artificially dried. It is made to revolve so that there may be as little running about as possible on the part of the boy who attends to this work.

Gas is also used for "ironing" (that is to say, finishing off the boots by ironing the surface of the leather) and "treeing" (that is, making the boots take the exact shape of the last on which they are modelled).

The gas is supplied to the centre of the apparatus; and the irons are heated within arm's-length of the ironers, so that no time is wasted (as was the case with the more old-fashioned systems) in passing to and from a stove with the irons.

It may also be mentioned that gas is employed for heating the irons for polishing the heels and soles of the boots and shoes. Another large boot factory in the same district uses gas entirely for power, lighting, and manufacturing purposes.

The Universal Servant.

The illustrations shown are but a very few of the many—the thousand-and-one—photographs that I could have used to demonstrate the multifarious practical applications that have already been made of gas in manufacturing processes. Only the limits of time at my disposal have prevented me from giving many others of equal interest and importance.

Fig. 20.

May I, however, in concluding my paper, express the hope that the little I have said, and the few illustrations I have shown, have sufficed to make it clear to you what a universal servant to man gas is? Our hats, collars, clothes, buttons, socks and stockings, umbrellas and walking-sticks; the making and blacking of boots, the books and newspapers we read, the pens with which we write, the motor-cars in which or the bicycles on which we ride—all owe something to gas in their production. Then, again, the stained glass in our churches, the fire extinguishers, the beds in which we sleep, and what is of vast importance to us as a nation, the armaments for our Army and Navy—shells and ammunition, guns, rifles, bayonets, swords—in the manufacture of each and all of these gas is largely used, and of my personal knowledge I know that the enormous output of

war material we have received from our manufacturers during the last few months could not have been made so rapidly without the aid of industrial gas appliances, many of which in their present economical, effective form are of comparatively recent introduction. It is, I venture to claim, largely due to the service of industrial gas apparatus that our new Army is in a position to take the field much earlier than otherwise could have been the case. Gas manufacturing is one of our greatest industries; no industry has ever been developed which has been of more service to the public. It has been in a letter to the *Times* said: "The stone is to no small extent rotten behind the crust, and analysis shows that this condition is entirely due to the action of coal smoke."

I am convinced that the further introduction of gas firing, in substitution for hard-fuel direct-firing, will aid materially in the solution of this great and urgent sanitary problem—the abatement of smoke. We may not live to see the supreme reign of this order of things, but each and everyone can do his part in advancing the rate of progress in the new era of industrial gas-heating; thus utilising to the

FIG. 21.

shown in many ways that the use of gas cookers, gas fires, gas water-heaters for domestic purposes in our large cities and towns, has been, in addition to many other advantages, accompanied by a marked increase in the number of hours of sunshine enjoyed by the community per annum, and a decrease in the number of dirt-producing and unhealthy fogs. This is emphasised pictorially by Fig. 20, showing a view of part of the roofs of London, among which the dome of St. Paul's is prominent, in the early morning in the height of summer, when domestic fires are not required, and before the factory chimneys have commenced their daily output of smoke; and by Fig. 21, showing the same scene on an ordinary working day. After an examination of the east side of Canterbury Cathedral, the architect to the Dean and Chapter of Canterbury, best advantage one of the greatest sources of power provided for industry by Nature, and so conserving that great national asset, our stock of unmined coal.

DISCUSSION.

THE CHAIRMAN (Mr. D. Milne Watson), previously to discussing the paper, expressed the regret he felt—which he was confident was shared by the meeting—at the absence of Sir Corbet Woodall, who had intended to take the chair. Sir Corbet had been looking forward to presiding at the reading and discussion of Mr. Thornton's paper, but had been forbidden by his doctor to be present. All would desire Sir Corbet's speedy return to health and strength. It had been a great pleasure, as was always the case when a man read a paper on his own subject, to listen to Mr. Thornton that evening. Mr. Thornton

was so eminent an expert that what he had to say had been of the highest interest. The numerous illustrations thrown upon the screen showed how great was the diversity of uses to which gas could now be put; indeed, there was hardly any manufacturing process to which it had not been applied, and the progress during the last few years had been of a most astonishing character. Sir Corbet Woodall, speaking of the present paper, had recently told him that he (Sir Corbet) had taken the chair, for the first time, at the Royal Society of Arts thirty-five years ago, and he believed that, at that time, not more than 5 per cent. of the gas used was employed for purposes other than lighting; to-day, however, no less than 40 per cent. was so used. That was splendid progress; but those who were gas men believed that this 40 per cent. only marked the beginning of the era of industrial application of gas. If any present were spared to come to a lecture at the Royal Society of Arts thirty-five years hence, the reader of the paper would then have a very different story to tell. As Mr. Thornton's paper had amply and fully shown, it was impossible to turn in almost any direction without finding that gas was being applied to industrial uses. The paper was the more apposite just now, as gas men were living under a cloud. The price of gas had unfortunately been necessarily raised, and many were feeling somewhat gloomy as to the immediate prospects. It was certain, however, that Mr. Thornton's paper had given a fillip to matters. The advantages of gas were so great and unquestionable as to compensate for the temporary difficulty in regard to price. After all, however, the price of gas was not such a very serious matter. Admitting that the price had gone up 18 to 20 per cent., yet, seeing that the manufacturer was able to make and deliver gas at an advance of 18 to 20 per cent., notwithstanding that coal had gone up some 300 per cent.—account being taken of carriage—he considered that the gas manufacturer was doing very well. In conclusion he would thank the author for a most interesting and illuminating paper.

Mr. W. E. Price considered that the paper required to be taken home and well digested by those who were not wholly familiar with the uses of gas; not till then would they begin to appreciate the value of the extent to which gas had been applied to work in this country. The point which Mr. Thornton had referred to early in his paper, namely, the amount of coal used in a crude and old-fashioned way—where it was burnt to destruction and much of its value lost up the chimney, as shown by the lantern-slides illustrating the roofs of a certain portion of London, presumably on an average day—proved the great advantage of gas, an advantage which he hoped would, before long, be increased by the compulsory abolition of the use of coal in the way in which it was still being used. The benefit to be derived was not merely financial; it was also an industrial benefit, and one of hygiene. The work Mr. Thornton had done, and the effort he had made, were very valuable.

Mr. F. W. Goodenough agreed with Mr. Price in thinking that the paper did not call for criticism or discussion, being a statement of the position of industrial gas at the present time. It was, he was sure, most gratifying to all connected with the gas industry to have heard the paper, which must have come as a surprise, even to the best-informed. He would only suggest that Mr. Thornton might have included the crematorium in his summary of uses. The author had shown that gas was used in connection with almost everything from early life, such as the heating of babies' food by the gas-ring, onwards. It was even used in connection with the humbler animals, the dogs' homes being a case in point. The Society was greatly indebted to Mr. Thornton for having devoted so much time and labour to the preparation of a very comprehensive paper, which would be treasured for a long time to come as a full record of the position of the industrial application of gas in 1915. It would be difficult, as the Chairman had suggested, for the most optimistic to forecast what would be the condition of the gas industry in 1950. It was, however, at least interesting to note that the percentage of gas used for purposes other than lighting had gone up from 5 per cent. to 40 per cent. Of course, if it were expressed in quantity the increase would appear enormously greater, because the total quantity of gas used to-day was probably at least ten times as much as thirty-five years ago. The figure would therefore be 40 per cent. on 1,000 instead of 5 per cent. on 100.

Sir Henry Trueman Wood, while not proposing to discuss the paper, desired to draw attention to the manner in which the hall of the Society was lighted. Thanks to the liberality and care of the Gas Light and Coke Co., and thanks especially to the influence of Mr. Goodenough, the Royal Society of Arts was happy in the possession of the latest form of gas lighting, and it seemed proper to the occasion that gas light should be used that evening to the exclusion of its rival, electricity, which, of course, was generally used with very satisfactory results. He would remind the meeting that the Society had done its share in promoting a knowledge of the progress of the gas industry. The Society had been among the first to use gas for its outdoor lighting—at that time it was not an illuminant which any reasonable being could introduce into a house. In the first quarter of the nineteenth century, the Society had also given prizes for the early utilisation of by-products, for improvements in gas manufacture, for the first gas-holder, and for the first gas-chandelier, of the old water-seal type. It was in the hall of the Society that Mr. Fletcher had described—the speaker did not think for the first time—his researches in what he had called "flameless combustion," at

which all the chemists had laughed. This, however, had—the speaker believed—since developed into the latest production, described before the Society last year, known as the "Bonecourt furnace." He considered that from the beginning of the use of gas to the present time, at which such an admirable and exhaustive paper on the practical applications of gas had been presented, the Royal Society of Arts, had done its share in extending a knowledge of the manufacture and uses of that important illuminant.

Mr. Leon Gaster did not propose to discuss the question of the use of gas for lighting purposes, but, from personal experience, he could corroborate what the author had said with regard to the industrial uses of gas. He was connected with large factories, for Government work, using gas for ironing purposes in the manufacture of clothing and caps, and he found the latest types of irons much more efficient than the old types. He could, indeed, have wished that Mr. Thornton had taken an opportunity of securing photographs from some clothing factories. The use by big caterers of gas for cooking purposes was another application to which he might refer. The speaker was himself connected with a company using millions of cubic feet of gas for this purpose, and the gas had proved a tremendous advantage, especially where there was not room for the storage of coal. Finally, he would refer to the application of gas in the drying and cleaning trades, where he had found it a great help.

Mr. Campbell M. Hunt remarked that papers fell usually under two categories, namely, those which were open to discussion and adverse criticism, and those which disarmed criticism by the quantity of valuable matter they contained. Mr. Thornton's paper was of the latter order. Sir H. Trueman Wood had referred to the fact that the Bonecourt boiler had been discussed by the Society last year, and, in this relation, the speaker would say that he understood considerable progress had been made, during the past few months, with the simplification of this boiler, and he believed the Bonecourt system of surface-combustion was being applied to industrial purposes. He would be glad if the author could say anything in regard to this point.

Mr. H. M. Thornton, in response to the question put by Mr. Hunt, remarked that he believed developments to have been made in the application of the Bonecourt system for industrial purposes. The company was, however, so well known, that he felt confident that if Mr. Hunt applied directly to the company they would give him any particulars he desired.

The Chairman then proposed a hearty vote of thanks to the author for his admirable paper, which was unanimously carried.

Mr. H. M. Thornton replied briefly to the general remarks which had been made, observing that the enthusiastic reception of his paper had repaid him well for any trouble it had given him to prepare. The subject of industrial gas was one that he had much at heart, and the study of it had interested him for some years. The more he investigated the matter the more convinced he felt that, by giving to the public all the particulars he could in regard to the many uses of gas from an industrial standpoint, he was performing a public duty. He had tried to show how great an advantage it had been to the nation in the present crisis; and if he had succeeded in establishing that the use of industrial gas furnaces had expedited—as he was satisfied it had—the turnout of Army and Navy requirements, and had brought nearer the day when hostilities would cease, he had done something to help the nation at a trying time.

The proceedings then terminated.

NEW TWO-COLOUR PROCESS.

At the meeting of the Royal Photographic Society, held on March 9th, Mr. G. E. Brown described a new process for producing coloured pictures by photography, which has been worked out by Dr. Kenneth Mees at the Kodak Research Laboratory in Rochester, New York. Mr. Brown remarked that most methods of colour photography depended on the use of three coloured lights projected on a screen, or upon the superimposition of three coloured impressions respectively complementary to the colours which were recorded in taking the negatives. An obvious step towards simplification was the substitution of two colours for three, as already adopted in the "Kinemacolor" process of cinematography, in which two negatives were used, red and green, and positives from these were projected alternately upon the screen through red and green filters.

In the new process, which from its origin was entitled "Kodachrome," two negatives were taken through red and green screens, and each negative was converted into a coloured positive by bleaching out the silver image, and dyeing the bleached film with a complementary colour. The two plates thus obtained were combined into a single transparency, which reproduced with very considerable accuracy the colours of Nature.

As a result of only two colours, red and green, being used in the process, the rendering failed in respect to blues, violets, magentas, and purples, but it did excellent justice to flesh tints of all kinds, shades of red, orange or green, and greys and blacks. The results at times appeared to show blues well by an optical illusion, blue-greens appearing blue in contrast with greens. The results appeared at their best when shown by artificial light. In taking the negatives the time required for two successive exposures by powerful artificial light was about three seconds altogether. If thought well the original negatives could be

reproduced by the medium of a positive, and retouching carried out at either the negative or positive stage.

A number of examples of the process were on view, being shown in each case, mounted in an illuminator having the appearance of an ordinary picture-frame with heavy moulding, and containing an electric lamp. It was seen that the colour rendering of flesh tints and the general photographic quality of the transparencies were of an exceedingly high order.

EMPIRE NOTES.

Colonial Fisheries.—A very important step has been taken by the New South Wales Government for the development of offshore fishing in Australian waters. They have acquired for this purpose three Grimsby trawlers, fully equipped and manned by crews of carefully selected North Sea fishermen. At a meeting in Grimsby, held last month, just before the trawlers left for their distant scene of operations, which was attended by the skippers and others concerned in the undertaking, Mr. Stead, the representative of the New South Wales Government, by whom the purchases and the necessary arrangements had been made, gave some particulars of the prospects of the scheme. He stated that on the coast of New South Wales there were very rich offshore fishing grounds, and also enormously rich surface fisheries. Most of the kinds of fish seen in the North Sea, Iceland, etc., were absent, but large numbers of flat-fish (flounders and soles) were to be met with. The principal fish were those of which the gurnard was the nearest type in English waters, about three or four feet long, called "flatheads." He considered that within the 100-fathom line, which averaged from 20 to 30 miles, there were about 9,000,000 acres of suitable trawling ground, inshore. There were many good trawling areas, but the principal fishing grounds were at a depth of from 80 to 150 fathoms. In the surface waters, there were large Spanish mackerel, which could be secured in great quantities with practically any sort of tackle and bait. The example set by the New South Wales Government may and probably will be adopted by other Australian State Governments, should the present venture prove a success. In the fisheries of the Dominions the Empire possesses a vast source of wealth, which hitherto, except in Canada, has been but little developed. Canada has found her fisheries to be a very valuable asset, the development of which is a subject of constant care on the part of the Department of Fisheries. The Forty-seventh Annual Report of that Department, just issued, shows that the total marketed value of all kinds of fish, fish products and marine animals, taken by Canadian fishermen from the sea and inland lakes and rivers during the fiscal year ending March 31st 1914, amounted to $33,207,748. There were 71,766 men employed in the work on 1,992 vessels, tugs and smacks, and 37,688 boats; while 26,893 persons were engaged in the fishing industry on shore in canneries, freezers, fish houses, etc. Of the total, there were 86,436 engaged in the sea fisheries and 12,173 in the inland fisheries. The extensive coast lines of Canada and Australasia, not to speak of other overseas countries under British rule, with their vast extent and variety of inland waters, afford practically illimitable opportunities for the development of this great industry.

War Equipment from Canada.—In October last the War Office sent a Purchasing Commissioner (Mr. F. W. Stobart) to Canada to obtain war equipment. Since that date the Commissioner has placed 255 contracts, of an aggregate value of $80,000,000. Of this sum, says the Toronto *Mail and Empire*, only $765,000 went to the United States for goods which Canada could not supply. More than nine-tenths of the expenditure has thus been made in the Dominion, keeping Canadian workmen and capital employed. An inventory of the purchases includes sheep-lined coats, sweater coats, wool vests, wool and cotton drawers, wool and leather mitts, socks, cap comfortings, flannel shirts, cholera bands, rubber boots, boot-laces, buttons, leather accoutrements, packs and haversacks, binoculars, razors, shaving brushes, mess tins, clasp knives, halters, railroad ties, posts and pegs, shovels, and pick handles. In addition, Colonel Barton has spent $5,000,000 for great-coats, jackets and trousers for the British armies. Altogether, $16,000,000 has been spent on woollen goods from Canadian mills, including $6,500,000 for khaki clothing, $1,250,000 for knitted articles, and $1,500,000 for blankets, upon which twenty-eight factories are now employed. Among the details of the purchases are 28,000,000 trouser buttons, 750,000 pairs of socks, 120,000 shovels, 1,500,000 woollen under-drawers, 250,000 cotton under-drawers, 10,000 sets of military accoutrements a week, 200 bicycles, 100 motor-cycles, and 200 motor-trucks. The Imperial Government has also ordered $30,000,000 worth of shrapnel shells, in the production of which, with cartridges and shell parts, 147 Canadian firms are engaged, which are aiming to produce 15,000 shells a day. The lead bullets come from the mines of British Columbia, and the steel and brass fittings and explosives are also of Canadian make. Even railway shops are being used in the manufacture of this war material. But not only is the British Government a large customer for war material. Russia is said to have bought $3,000,000 worth of Ross rifles, while the French Government's orders for saddlery, harness and other goods run into large figures. It is estimated that the war outlays by the British and Allied Governments will amount to several hundred million dollars. If to these purchases of war material there be added the orders for foodstuffs, which will become increasingly large as the war proceeds, the advantages offered by the Dominion to the Allies for the supply of the necessaries occasioned by the war will be incalculable.

Canadian Industrial and Labour Conditions.—The Department of Labour at Ottawa, in its latest report published in the official *Labour Gazette*, reviews the present industrial and labour conditions of that country, which may be regarded as encouraging, considering the dislocation of trade caused by the war. The Department reports a slight reduction in the number of persons unemployed throughout Canada, which it ascribes mainly to the work being provided by municipalities to meet the present need, but a large contributing factor is found in the fact that "the internment of aliens of enemy nationality continues to give a very considerable measure of relief." From this statement it may be inferred that there is, in the towns, a large foreign element, which has hitherto competed with Canadians and with British immigrants in the labour market. In regard to agricultural employment, an encouraging note is struck, as we are told that many farmers, who had left their farms for the cities, are going back to the land. Evidently the expectation of good prices for their produce is leading a number of men who had, with their families, given up farming for the attractions of business life in the towns, to return to their holdings or to acquire others. This is borne out by the number of applications for homesteads with which the Land Department is being called upon to deal. The report on lumbering has also its favourable indications, owing to the increased need of pulp-wood in view of the demand for paper arising from the reduction of supplies from Scandinavia and the total cessation of exports from Germany. There are other satisfactory features, such as the demand for pit-wood and the large orders for lumber which are being received from Great Britain and South Africa. Owing to decreased railway consumption, and the general reduction in industrial activity, the coal output has been reduced. But asbestos and copper-mining show signs of improvement as compared with the early days of the war. In dealing with manufactures the report states that conditions are generally dull, except in those factories which are working on war orders, to which reference has been made in a previous paragraph. Railway conditions are quiet, though on certain lines in the West construction is proceeding.

The Australian Rainfall.—Some interesting particulars of the rainfall of Australia are given in the *Scottish Geographical Magazine*, in an article by Mr. B. C. Walters, who states that the Australian rainfall covers three periods in the year—(*a*) mid-December to mid-April: greatest intensity in the north, maximum effect in February; (*b*) mid-April to mid-August: winter rains, especially in the south-west, maximum in June; (*c*) mid-August to mid-December: relative dryness throughout the continent, maximum dryness in November. The rainfall of the continent swings with the sun, and is associated with the oscillation of the track of the anti-cyclone centres, between 28° and 35° S., whose passage from west to east, according to Dr. W. J. S. Lockyer, is the dominating factor controlling Australian weather, as also that of South Africa and South America in similar latitudes. In the summer, when the anti-cyclones move along their southern course, cyclonic disturbances from the sea affect the northern part of Australia, bringing the rains which follow, though lagging considerably behind the vertical sun. When, on the other hand, the anti-cyclones move along their nothern course, excessive disturbances affect the southern shores of the continent. In both cases the cyclones traverse the sea, which ensures abundant precipitation. The winter rains are especially pronounced in the south-west of Australia, Perth supplying a better example of the seasonal variation than either Adelaide, Melbourne, or Hobart, just as Cape Town excels both East London and Port Elizabeth in this respect. The whole of the western part, south of 20° S., is affected by the winter rains, but in the east this rainy season does not appear in similar latitudes. The dry season of the southern spring seems to be associated with certain temperature conditions, for besides being the time when the winter rains are dying away and the summer rains approaching, it is the period when temperatures over the land are markedly higher than those of the sea, the special dryness of November being accompanied by the maximum difference in air temperature between land and sea. The recent season has been one of unusual drought throughout Australia, and had it not been for the conservation of water—practicable, however, only to a limited degree owing to the prolongation of the drought—to artesian supply, and to the systems of irrigation in partial operation, the distress in the agricultural and pastoral districts would have become much more acute. The present reports are happily encouraging, as there has ensued an abundant rainfall which gives promise of a good season.

Indian Manufactures and the Present Opportunity.—The Indian Government and Indian manufacturers are recognising the need of availing themselves of the opportunities for developing their manufacturing industries afforded by the present condition of affairs, as is shown in the efforts and proposals constantly reported in the Indian press. In the *Pioneer* (Allahabad) attention is drawn, by the secretary of the Upper India Chamber of Commerce in Cawnpore, to the steps taken to induce manufacturers to consider the possibility of supplying the goods hitherto imported from enemy countries, the value of which amounts to £11,304,000, or 9 per cent. of the total imports, and to the action of the Indian Government in collecting samples of these goods and exhibiting them side by side with those of competing Indian manufacture. A writer in *Commerce* (Calcutta) advocates the starting of paper-mills, on account of the closing of German and Austrian sources of supply. From those countries in 1912-13, it is stated, India imported paper, chiefly

of the coarser quality, to the amount of £192,210. Up to now, the writer says, want of capital and of expert directors has militated against any development of the industry; under present circumstances these difficulties ought not to be insuperable. He affirms that India possesses great natural resources in her vast forests, in her great expanse of land covered with grasses suitable for paper pulp, in her excellent railway and canal systems, and in the cheap and intelligent labour obtainable all over the country.

CORRESPONDENCE.

THE DECORATIVE TEXTILE INDUSTRIES AND THE DESIGNER'S RELATION THERETO.

The reader of the paper on the above subject makes misuse of the occasion afforded him by his attack on Schools of Art and their masters. His remarks suggest ignorance of both, and it is with surprise that one reads in his subsequent letter that these "somewhat severe criticisms" were made in the hope that they would not go unchallenged.

May I call attention to an expression by Mr. Bernard Shaw in the discussion on "Shakespeare's Profession," reported on p. 336 of the *Journal*, to the effect that "In any period in which Art was active there were two orbits which never crossed each other. One was the orbit of the man who dealt with an established form of Art and carried it to its highest perfection, always . . . a contemporary form of Art. The other was the orbit of the man who, finding established forms of Art altogether repugnant to him . . . and believing them to be entirely wrong from beginning to end, immediately started on a forlorn hope and tried to turn the public taste upside down."

As to Mr. Wilcock's criticisms, one wonders, seeing he is so unacquainted with the schools, by whom they could be inspired, until he relates his experience of a student of the Royal College of Art some three years ago. It would be interesting to have this student's side of it. One can hardly think that a man who had served his "apprenticeship in the studio of a Manchester printer," and who was clever enough to win a scholarship from the Manchester School of Art to the Royal College of Art, after his term there—even if his "artistic and technical knowledge of cotton-printing had lain fallow during his college days," and "had become obscured by all the varied and perfunctory studies of other industrial arts and crafts"—would be so useless. He certainly would be worth "£5 per week," if given a fair trial.

But from his letter, Mr. Wilcock's quarrel is not with the Royal College of Art only. The schools generally are the object of his attack, as well as their masters, although he asks for credit for a full appreciation of what the schools have done and disclaims abuse. "The design master, a professional architect," can no doubt defend himself from the aspersions cast at him; but the letter to the headmaster certainly seems to require an answer.

As one who has had many years' connection with Schools of Art (London and provincial), as student, teacher, and headmaster, following on a practical training in woven textiles (all branches except dyeing), and who is in full sympathy with the industrial aim in Art instruction, I say emphatically that, if the schools suffer from any one thing, it is just this unreasonable and carping criticism, so frequently levelled at them by those who are not acquainted with them. I would say that the country has much to gain by the multiplying tenfold of its opportunities for artistic education through the Schools of Art.

The Art School is a necessary adjunct to our industrial life, and an essential part of any truly educational system. The factory, the workshop, and the design room will give the worker all he will need of the technical side of his work; but commercial exigencies do not allow of his getting what the schools do afford of artistic study.

The student needs opportunities under guidance for study from Nature and the life, study of historic development and characteristics of styles. The work of the school is rightly elemental and foundational, experimental if you like, and must not be in view of fashion or of passing crazes—the pupil will have enough of that when his days of study are past; but the school is not founded to turn out designers any more than the primary school to turn out ready-made clerks.

Nor will design look after itself as asserted. The School of Art must look after it, and will train the inventive faculties, helped by opportunities in practical craftsmanship such as most schools now afford. Many masters are actual craftsmen, who, so far as painting is concerned, rather practise it as relief from more technical work, than teach as disappointed painters. I know admirable examples of this. And if a student is so enamoured of such work as to seek to find a market for his production, who shall say him nay?

But there is too tardy a recognition of these schools, too restricted a control of their energies. Mr. Wilcock would bring to bear a control that would throttle them completely. Why should trade jealousies militate against artistic development? Yet such is the unfortunate case. Why should not employers, managers, and workmen encourage to the full every effort towards artistic excellence in production? Why should not youth have every opportunity for developing artistic faculties? Every effort is made on the commercial side and also on the technical. Well might the Schools of Art languish and the country take a back seat artistically.

I plead for an extension and an expansion of the Schools of Art rather than a curtailment, as Mr. Wilcock suggests. The minds of our youth need

artistic training: so shall we have a public appreciating artistic productions. How is it that artistic instruction is not part of the work of the primary school? Are the minds of children to develop on commercial and technical lines only? Shall they not have a chance in the artistic direction? It is high time we were more liberal in the matter of artistic opportunity. To curtail these is to cripple ourselves.

There should be a School of Art within reach of all our youth (male and female). They may not all become producers of the artistic, but they may all grow up to be choosers and purchasers, and so will the existence of artistic industry be maintained. If this were so there would be no pandering to the public by the designer, and he would be a man esteemed and valued, his work and ability being understood and appreciated.

Mr. Paulson Townsend says, "It is deplorable that we allow the natural instincts for the beautiful (of the nation) to lie fallow." And herein is the gist of the whole question. It is neglect educationally traceable in the elementary education of the child. Education on commercial lines alone tends to drive out what exists of artistic sympathy. Admirable means are taken by some authorities, the opposite of what Mr. Wilcock suggests; but generally such a policy is obstructed, to our very great loss as a nation. Municipal and State support of this policy is needed. Let us have the artistic educationalist and his ideals, but do not reorganise all the life out of us. The schools have had enough. And let us get out of mechanical ruts, being mindful that the character of a nation may be expressed in its Art.

CLARENCE MAWSON, A.R.C.A. Lond.

[This correspondence must now cease.—ED.]

PATENT LAW REFORM.

In the report of the discussion on Mr. J. W. Gordon's paper on Patent Law Reform, I am represented as having stated that the cost of a German patent was £17, of a British patent £7, and of a United States patent 7*s*. This scarcely conveys the sense of what I said. In comparing the cost of patents in the principal countries of the world, I assumed a patent to be maintained for the full term. I added together the fees on application, grant, and maintenance, divided the sum by the number of years, and thus arrived at the average *annual* cost. A German patent maintained for the full term costs a trifle over £17 per annum, a British patent a trifle over £7 per annum, and a United States 8*s*. 6*d*. Why should a German patent be valued at forty times that of a United States patent? Is a patentee likely to make a sovereign out of his German patent for every sixpence he makes out of his United States patent? If not, why should he pay forty times as much for protection? I do not suggest that no inventions are worth protecting on such exorbitant terms as those exacted by Germany; but as one cannot have different scales of fees for different classes of invention, the scale should be such as not to exclude improvements of utility and merit, although perhaps of moderate industrial importance.

I may be told that, as regards British patents, I should be the last to criticise the scale of renewal fees at present in force, as it was adopted at my suggestion (in 1889). The scale was based on the idea of making the amount of the fee correspond with the year in respect of which it was payable, and to that extent was more convenient than the irregular scale previously in vogue. At that time, however, the main object was to get a substantial reduction in the scale of fees then prevailing, and amounting to £150. The struggle was so far successful that the amount of these fees was reduced from £150 to £95; but I think it would be greatly to the advantage of the community if they were further reduced, and the yearly increment made 10*s*. instead of 20*s*. If this were done, the renewal fees would amount to £47 10*s*.; but if the term of the patent were at the same time extended from fourteen to, say, seventeen years, there would be a further £24 payable. In addition to this, many more patents would be maintained, whilst others would be maintained for longer terms; so that, on the whole, patents would be popularised without entailing any loss of revenue.

Mr. Gordon's remarks on the subject of compulsory licences were of a highly interesting and instructive character, but he did not say much about the revocation of patents for non-working. I am entirely in favour of the compulsory licence as a remedy for obstructiveness, subject to the provision of appropriate means for administering the remedy. It is generally recognised that the machinery provided for giving effect to this provision of the Patents Act of 1907 is unsatisfactory. It is for lawyers to devise means of a workable and effective character, and I hoped that Mr. Gordon would have some suggestions to make on the subject. Many matters of quite as much importance as licences under patents are settled by arbitration, and it might be worth considering whether applications for the grant of compulsory licences could be dealt with by such or similar means. If the compulsory licence idea, which is good in itself, could be worked out in such a manner as to admit of its being put into operation at least as readily as the arbitration clause in any ordinary agreement, the provision for the revocation of patents for non-working would become not only unjustifiable but unnecessary.

We are all agreed as to the desirability of promoting home industries and the employment of native labour; but the grounds upon which a patent may be attacked cannot be extended without rendering patent property more unreliable, and deterring persons from risking capital in the establishment of industries based thereon. If it be desired to encourage the establishment of new industries, everything should be done, not to destroy patents but to facilitate their maintenance. In order to induce a manufacturer to undertake

the labour and pecuniary risk incidental to the establishment of a new industry, one of the first essentials is the existence of a sound patent, on which he may rely for protection for at any rate a limited term. So long as the patent remains in existence there is some chance of manufacture being undertaken under its protection, and if that be the object in view the worst possible course is to destroy the patent.

Our Patent Law might undoubtedly be improved in many respects, to the great advantage of the community, but the subject is not one in which the public manifest any particular interest. There are societies for promoting the welfare of horses, dogs, cats, and other animals; but there is, as far as I am aware, no organisation whose special function it is to promote the interests of inventors and of those who turn inventions to the commercial and industrial advantage of the country at large. I have often hoped that the Royal Society of Arts would see fit to take the lead in this matter. There are many improvements which might be urged, but I will merely summarise the few points I have already touched on:—

(*a*) Reduction in the fees for maintenance by (say) one half.

(*b*) Extension of the term of Letters Patent from 14 to (say) 17 years.

(*c*) Simplification of the machinery for procuring the grant of compulsory licences in cases of non-working.

(*d*) Abolition of revocation for non-working.

(*e*) Extension of the official search as to novelty, so as to render it at least equal to that made in the United States.

G. G. M. Hardingham.

GENERAL NOTES.

Revival of the Bêche-de-Mer Industry in the Bahamas.—Recently a shipment of bêche-de-mer, valued at about £8,000, was made to Chinese ports from the Bahamas, which revives an industry that for a period of forty years promised well. The sea slugs in the waters of the Bahamas appear to be of high quality as compared with those of the East Indies and Australian coast and the atolls of Polynesia. In the south-western section of the Pacific the industry is valued at more than £2,500,000 annually, but the supply seems to be getting limited. It is said to be likely that, with proper selection with reference to size, colour, and correct method of curing, and the facility for shipment through the Panama Canal, the Bahamas may in the near future benefit from an increased demand for this article. Even in Paris bêche-de-mer is served at many restaurants, although the greatest quantity is required for the people of China.

The Greek Fishing Industry.—Fishing is an important industry along the entire coast line of Greece and in the neighbouring waters. The principal fish caught in local waters are the tunny, the sardine, mullet, smelt, gudgeon, mackerel, etc. To a great extent the fish taken by local fishermen are consumed within the country. In addition to the deep-sea fishing, the Government owns some sixty-seven fish-breeding ponds and fishing grounds, both in salt and in fresh waters. The privilege of taking fish from these waters is granted for periods of ten years. Up to 1911 fishing was carried on in local waters in an unsatisfactory manner, and one prejudicial to its best interests. In that year the Government engaged the services of an Italian expert, and established a bureau of fisheries in the Ministry of National Economy. Within the succeeding two years the results achieved by the bureau have been satisfactory. Measures are now taken for the protection of the fish at proper seasons, the kinds of net to be used are prescribed, etc., and provision is made for inspections from time to time by Government inspectors.

Production of Quicksilver in Italy.—The total production of quicksilver in Italy in 1914 amounted to 1,072,629 kilogrammes (2,364,700 English lbs.). This was furnished by the following mining firms and companies:—

	Kilogrammes.
Società anonima Miniere dei Monte Amiata	740,025
Società anonima Stabilimento minerario del Siela	181,332
Eredi Swarzenberg	91,045
Società an. Miniere Cinabrifere Bagni San Filippo	46,220
F. Menicanti	14,007
Total	1,072,629

The Dairy Industry in Switzerland.—A Zurich journal states that there has been a serious decrease in the production of milk during the past winter in many parts of Switzerland. As compared with the similar period in 1913, the falling-off during last January has been very marked in the following cantons: Berne, 28 per cent.; Lucerne, 26 per cent.; Aargau, 25 per cent.; Neuchâtel, 21 per cent.; Friburg and Soleure, 20 per cent.; Thurgau, 18 per cent.; Vaud, 13 per cent.; St. Gall, 12 per cent.; Zurich, 9 per cent.; and Geneva, 2 per cent. In fact, the dairymen of Switzerland have found it difficult to meet the demands of their customers. The federation of dairymen of north-eastern Switzerland, which has been established for the last ten years, comprises 256 separate syndicates as well as 57 independent firms, representing 8,088 members, who own 31,596 milch cows, producing 1918 hectolitres (40,086 gallons) daily. Fresh butter for the table is fetching in many markets as much as 4 francs per kilogramme (1*s.* 6*d.* per lb.). In the German-speaking cantons the prices range between 3 francs and 3·90 francs per kilogramme (1*s.* 3*d.* to 1*s.* 5½*d.* per lb.) at the present time.

THE CREAM-SEPARATOR INDUSTRY IN SWEDEN.—The manufacture and marketing of cream separators has become an important Swedish industry. A factory in Stockholm is one of the largest in the country. Many of these establishments have branch factories and selling agents in almost every country in the world. Statistics for 1913 are not yet available, but the exports for 1911 and 1912 were valued at £750,000 and £770,000 respectively. Russia is the best single market for Swedish cream separators. As in many other articles manufactured in Sweden, the close proximity to Russia gives a decided advantage over other foreign competitors. Germany, before the war, was the next best customer, taking about half as many separators as Russia. This shows that the German home industry in this respect is not as highly developed as it is in England and the United States, which countries, more or less, supply their own needs. One reason for the success of this industry in Sweden is the enterprising methods of many of the manufacturers, who issue splendidly illustrated catalogues, printed in at least four languages. Travelling salesmen and resident agents, furnished with literature of this nature, together with a thorough knowledge of their business, are highly successful in effecting sales.

THE ESSENTIAL OILS OF RÉUNION.—The exports of essential oils from Réunion have of late been steadily increasing. These oils are as follows: Geranium oil, which in 1913 was exported to the extent of 94,600 lbs.; ylang-ylang, or cananga oil, which is derived from the flowers of *Cananga odorata*, and is regarded as one of the most delicious odours in the market. This is also produced in the Philippines. The amount of this essence exported from Réunion in 1913 amounted to over 4,000 lbs., and in future years this quantity is expected to be much exceeded. Veti-vert, derived from the grass *Vetivera zizanoides*, is the most viscid of all the essential oils. The demand for it is not very great, and it is not expected that there will be any increased production in Réunion. The amount exported from the island in 1913 was 4,600 lbs.

RUSSIA'S SURGICAL INSTRUMENTS.—A Russian correspondent of the *Lancet* writes that the problem of the supply of surgical instruments, since importation has become so difficult owing to the war, is being partly solved by the Russian cottage or home industrialists, particularly in the village of Pavloff, in the Nishegorod government. The peasant workers there have delivered various surgical instruments of such quality as to convince local traders that not only German, but foreign goods generally of the kind, can now be dispensed with. One large Moscow house that specialises in these goods is establishing a workshop of its own at Pavloff, and is opening there a bureau for giving cash advances to peasants who have devoted special attention to the making of surgical instruments. Instruments received from Sweden are of high quality, but expensive. A parcel of excellent instruments has been received from Japan at the Soldatenkoff Hospital, Moscow, and similar consignments are expected from England *viâ* Copenhagen.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock (except where otherwise announced) :—

MARCH 24, at 5.30 p.m.* — LADY LUGARD, "The Work of the War Refugees' Committee." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, will preside.

APRIL 14. — T. THORNE BAKER, "The Industrial Uses of Radium."

APRIL 21.—MORETON FREWEN, "The State and the Fisherman."

APRIL 28.—A. S. E. ACKERMANN, B.Sc., Assoc. M.Inst.C.E., "The Utilisation of Solar Energy."

MAY 5. — AUGUSTUS VERNON HARCOURT, D.C.L., LL.D., D.Sc., F.R.S., "On an Economical and Smokeless Grate, and on the Measurement of the Efficiency of Open Grates."

INDIAN SECTION.

Thursday afternoons :—

APRIL 15, at 5 p.m. — PERCEVAL LANDON, "Basra and the Shatt-ul-Arab." The RIGHT HON. EARL CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., will preside.

MR. M. M. S. GUBBAY, I.C.S., having been recalled to duty by the Government of India, will be unable to read the paper on "Indian Trade and the War," which was announced for May 13th.

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock :—

MAY 4.—S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials." The HON. SIR GEORGE H. PERLEY, K.C.M.G., Acting High Commissioner for Canada, will preside.

Dates to be hereafter announced :—

C. H. SHERRILL, "Ancient Stained Glass."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

* The hour of this meeting has been changed from 4.30 p.m. to 5.30 p.m.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

M. H. BAILLIE SCOTT, "House Building: Past and Present." Three Lectures.

Syllabus.

LECTURE II.—MARCH 22.—*Houses in the Past in this Country.* Three main periods: (1) The craftsman or mediæval period, when the art of building flourished; (2) The scholar, or Renaissance period, when the building art became "tongue-tied by authority"; (3) The shopkeeper, or commercial period—The distinguishing features of the three periods set forth as an allegory—The trades guilds—The spirit and methods of the old craftsmen—The scholar spirit—The commercial spirit.

LECTURE III. — MARCH 29. — *Houses of the Present.* The average house of the craftsman period adorned the world—The average modern house disfigures the world—Normal modern building a disease rather than an art—The causes and cure of this disease—Difficulties of the architect—Building by-laws—The qualities of various types of houses discussed—An ideal house described.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 22 ..ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. M. H. Baillie Scott, "House Building: Past and Present." (Lecture II.)

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. E. B. Havell, "The Foundation of Indian Economics."

Geographical Society, Burlington - gardens, W., 8.30 p.m. Dr. W. S. Bruce, "Spitsbergen in 1914."

Architectural Association, 18, Tufton-street, S.W., 8 p.m. Mr. Hilaire Belloc, "The Changes in the Conception of Artificial Permanent Defence, including those indicated by the Present Campaign."

TUESDAY, MARCH 23...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Sir T. Barclay, "The Hague Tribunal: its Constitution and Potentialities."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. G. Frazer, "The Belief in Immortality among the Polynesians." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. 1. Discussion on Sir T. Mason's paper, "The Improvement of the River Clyde and Harbour of Glasgow, 1873-1914." 2 Mr. C. W. Anderson, "On Impact Coefficients for Railway Girders."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. A. E. Morton, "Our Cottage Homes."

Zoological Society, Regent's-park, N.W., 8.30 p.m. 1. Mr. W. R. Ogilvie-Grant, "Exhibition of Partridges and other Game Birds." 2. Dr. F. E. Beddard, "Contributions to the Anatomy and Systematic Arrangement of the Cestoidea. XVI. —On Certain Points in the Anatomy of the Genus *Amabilia* and of *Dasyurotænia.*" 3. Mr. R. Lydekker, "The True Coracoid." 4. Mr. J. T. Cunningham, "The Artificial Formation from Paraffin-Wax of Structures resembling Molluscan Shells." 5. Mr. B. F. Cummings, "On Two new Species of *Polyplax* (Anoplura) from Egypt."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. W. R. Cooper, "Electric Cooking, mainly from the Consumer's Point of View."

WEDNESDAY, MARCH 24...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., **5.30** p.m. Lady Lugard, "The Work of the War Refugees' Committee."

Naval Architects, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 11 a.m. (Annual Meeting.) 1. Presidential Address. 2. Professor J. J. Welch, "The Watertight Subdivision of Ships." 3. Mr. K. G. Finlay, "The Increase of Safety Afforded by a Watertight Deck." 3 p.m. 1. Mr. J. Reid, "The Influence of Discharging Appliances on the Design of Large Ore-Carriers." 2. Mr. J. Montgomerie, "The Scantlings of Light Superstructures." 3. Mr. C. F. Holt, "On the Strength and Spacing of Transverse Frames."

Literature, Royal Society of, 20, Hanover-square, W., 5 p.m. Mr. P. H. Newman, "The Greek Trireme, with some remarks on Ancient Sea Power and Theories of Propulsion."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m Mr. I. C. Hannah, "Some Irish Religious Houses."

THURSDAY, MARCH 25...Naval Architects, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 11 a.m 1. Mr. F. W. Lanchester, "A Contribution to the Theory of Propulsion and the Screw Propeller." 2. Mr. A. W. Johns, "A Comparison between the Results of Propeller Experiments in Air and Water." 3. Mr. J. L. Kent, "Further Model Experiments on the Resistance of Mercantile Ship Forms: The Influence of Length and Prismatic Coefficients on the Resistance of Ships."
3 p.m. 1. Mr. C. E. Stromeyer, "The Law of Fatigue Applied to Crankshaft Failures." 2. Mr. Linton Hope, "The Effect of Beam on the Speed of Hydro-Aeroplanes." 3. Mr. E. F. Spanner, "Notes on the Cross Curves and GZ Curves of Stability."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Mr. C. E. Wallis, "The Care of the Teeth."
7.30 p.m. Annual Meeting.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. Strahan, "The Ground beneath London."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. M. W. Brockwell, "The Present War, and its Relation to the Art History of Western Europe."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. W. L. Preece "Telephone Troubles in the Tropics."

FRIDAY, MARCH 26...Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir J. J. Thomson, "Experiments in Slow Cathode Rays."

Geologists' Association, University College, W.C., 8 p.m.

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, MARCH 27...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Recent Researches on Atoms and Ions." (Lecture VI.)

Journal of the Royal Society of Arts.

No. 3,253. VOL. LXIII.

FRIDAY, MARCH 26, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 29th, 8 p.m. (Cantor Lecture.) M. H. BAILLIE SCOTT, "House Building: Past and Present." (Lecture III.)

CANTOR LECTURES.

On Monday evening, March 22nd, Mr. M. H. BAILLIE SCOTT delivered the second lecture of his course on "House Building: Past and Present."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 24th, 1915; COLONEL SIR THOMAS HUNGERFORD HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Vice-President and Chairman of the Council of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

MacCaw, Vivian Hardy, 21, Strand-road, Calcutta, India.

Pardiwalla, Jehangir Pestonjee, Hotel Majestic, Bombay, India.

Saunders, Alfred Oliver, 102, Osborn-road, Sparkhill, Birmingham.

Spence, Charles Stewart Traill, Plantation Waterloo, Nickerie, Surinam, Dutch Guiana.

The following candidates were balloted for and duly elected Fellows of the Society:—

Baltimore, Professor Jeremiah D., Armstrong Technical High School, Washington, D.C., U.S.A.

Murphy, Joseph Plato, Zorgenhoop, West Bank, Berbice, British Guiana.

The paper read was—

THE WORK OF THE WAR REFUGEES' COMMITTEE.

By LADY LUGARD.

I have been asked to speak to-day about the work of the War Refugees' Committee.

The work of the War Refugees' Committee is intimately associated with what will, I believe, hereafter be regarded as one of the most acutely pathetic chapters of our island history. Because we are an island, because a stretch of sea lies between us and Europe, because, above all, we have a Navy which for a thousand years has known how to defend that strip of sea, we have been able, not for the first time in our history, to offer refuge to a people stricken and driven out from their proper home.

There is no need for me to speak now of what Belgium has done—we all have the knowledge in our hearts. In the Titanic struggle in which we are engaged Belgium bore for a time the burden of the world, and the world can never forget, and never repay.

We all remember the shock of horror with which we read the first accounts of the atrocities perpetrated at Visé and Liége. But we have almost forgotten that only a few days before the outbreak of this war our eyes were turned towards another theatre of disturbance, and the outbreak of civil war in Ireland was the catastrophe we feared. For a moment I must recall it in connection with the refugees, for, strange as it may seem, the War Refugees' Committee is, in a sense, the lineal descendant of the Ulster Council.

The preparations of Ulster in the early summer of last year were sufficiently public to be known to anyone who chose to be acquainted with them. Like most Irish Protestants, I was aware that in view of coming contingencies arrangements had been made for the removal of many thousands of women and children from the area which was likely to become a theatre of war.

These arrangements had been made with great thoroughness. Registration and all other necessary forms had been prepared, transport had been organised, and safe homes had been secured in England. The outbreak of European war mercifully averted the misfortune of war in Ireland, and when the news of the first atrocities came through from Belgium they suggested the idea, "Why not use the Ulster organisation to get the Belgian women and children out, if possible, from under the German guns?" At that time we had, of course, no conception of the development which the refugee movement was ultimately to take. The thought in my mind was mainly of women and children. I telegraphed to Captain Craig to ask whether, if such a scheme proved feasible, he would let me have the use of the Ulster organisation. He telegraphed back immediately that everything they had was at my disposal for such a purpose. He sent me all their registration forms—forms which we are to-day using at the War Refugees' Committee—and put me immediately in touch with people who had the necessary information. In twenty-four hours I had the embryo of an organisation in my hands.

But it was evidently necessary to change what I may call the "sentiment base." The next step was to approach the Catholic Church and to ask of Cardinal Bourne that the Catholic institutions of Great Britain and Ireland might be circularised in order to ascertain how many homes of undoubted security could be placed at the disposal of Belgian refugees. I was received with a cordiality which, I would like to say here once for all, the Catholic Church has constantly maintained towards the movement. I was assured by Monsignor Bidwell, whom Cardinal Bourne deputed to discuss the matter with me, that assuming the movement to be properly organised and to be viewed with favour by the Government, the Catholic authorities would be very ready to help.

With this amount of preparation I approached the Foreign Office, and was assured of the sympathy of Sir Edward Grey. The Local Government Board signified their approval, and the Foreign Office was good enough ultimately to arrange an interview for me with the Belgian Minister, directing me that in placing the scheme before him I was to inquire what steps his Government, in the event of their viewing the proposal with favour, would take to make the scheme known in Belgium. In accordance with these instructions I laid the scheme before the Comte de Lalaing, and in due course an answer was received from the Belgian Government accepting the proposal with gratitude, and saying that they would make the scheme known in Belgium, and would direct intending refugees to come to Ostend, whence it was understood that we would take steps to bring them away.

While these negotiations were in progress the position in Belgium was becoming every day more acute, and on a certain Saturday, August 22nd, I was informed by Mr. Reyntiens and Mr. Wintour, of the Board of Trade, that they had the promise of a transport from the Admiralty, with which they were immediately going to fetch over refugees, and that they hoped to return on the following Monday with a ship-load. I asked Mr. Reyntiens how many they proposed to bring back. He said, "As many as we can get—anything from 100 to 1,000." To the inquiry, "What do you propose to do with your refugees when you bring them back?" his reply was, in effect, "We leave that to you!" There was no time to discuss the matter; it was necessary for him to go at once and get his papers ready, and I was left on Saturday morning in full sympathy with the adventure, but with the knowledge that on Monday I might be expected to receive in England 1,000 refugees.

No committee had as yet been formed. It was evident that between Saturday and Monday a committee had to be formed. I will not delay you with a relation of the details of that Saturday and Sunday afternoon, interesting as they were at the moment to those engaged in the work. The only condition which I made was that the committee should have no politics and no religious distinctions, and it is enough now to say that, thanks mainly to the exertions of Mrs. Alfred Lyttelton and Mr. H. E. Morgan, a committee was formed under the required conditions and in the required time, Lord Hugh Cecil consenting to be our chairman and Lord Gladstone our treasurer.

By the kindness of Mr. F. Norie-Miller, General Manager of the General Accident Fire and Life Assurance Corporation, Ltd., offices were placed at our disposal entirely free of charge. The embryo of a clerical and typewriting staff was secured. A name was chosen. An appeal was sent to the papers on Sunday night, and as a net result of our exertions we were enabled on the following Monday morning to take possession as a committee of the empty offices which have since developed into the well-known headquarters of the War Refugees' Committee at Aldwych. That first morning we had hardly pens and ink, we had not chairs to

sit upon, the offices were almost entirely without furniture, and while we were trying to organise our immediate plan of operations the response to our appeal, which had appeared only in that morning's papers, took the embarrassing, if at the same time encouraging, form of no less than 1,000 letters, all containing offers of hospitality and help.

The response of the country to the movement was absolutely extraordinary. The 1,000 letters of that day became 2,000 on the following day, then 3,000, then 4,000, then 5,000, and on the day on which we received 5,000 letters there were also 1,200 callers at the office. Every letter and every visitor brought proposals of help in one form or another. Within a fortnight we had at our disposal hospitality for 100,000 persons. Cheques, clothing, food, offers of personal service, flowed in upon us. I could spend hours rather than minutes in telling you the details of that first outpouring of public generosity. The sense of the country was made absolutely clear that, if it could not share the acute suffering caused to the people of Belgium by the war, it desired to diminish that suffering by every means that it possessed. These offers came not from one class nor from one place, but from all classes and from all places. Catholic and Protestant, Jew and Nonconformist, high and low, rich and poor united, all unaware, in a spontaneous tribute of sympathy and respect. Nations, like individuals, have their moments of unconscious self-revelation. It was a moment which unmistakably revealed the heart of England.

The enthusiasm and volume of the movement were cheering. They brought with them accompaniments which it must be admitted were difficult to cope with. We were soon accused, and justly accused, of not answering our letters, of not acknowledging our cheques, of not receiving our visitors with due consideration. It was all true! To have done otherwise was a physical impossibility, for what were we among so many? We were only a willing company of amateurs suddenly called upon to deal with the conditions of a large business created in three days. And while this volume of external business was pouring in, the true object of our existence remained, in our opinion, the providing of homes for our coming guests. We contented ourselves with locking up our cheques, and gave our thoughts to the refugees.

They began to come in the first day. They increased in numbers, not being immediately brought in shiploads, but trickling through on their own account from various sources to the number of perhaps 100 or 150 a day. Our first difficulty with regard to finding homes for them was met by the kindness of Sir James Dunlop-Smith, who obtained from the India Office permission to place at our disposal a small house at 49, St. George's Road, usually occupied by the King's orderlies, but standing at the moment empty and furnished. This was the first place of refuge offered in this country to Belgians. It seemed to us a suitable coincidence that it should come, even indirectly, from the King. The Borough Council of Camberwell was, if my memory serves me, the next to offer us beds for Belgian refugees. They had organised Dulwich Baths as a hospital, and they placed at our disposal between fifty and one hundred beds. Battersea followed their example. Private offers were added to these, and in two or three days we had a couple of hundred beds upon which we could count.

We reached the third day of our existence before any news came of the shipload of refugees for whose reception the Committee had been so hastily organised. It was on Wednesday evening, at about half-past seven o'clock, as we were separating after a heavy day's work, that a telegram was brought in saying, "One thousand refugees arriving Folkestone to-night. Can you take 500 in London to-morr[illegible] The moment had come. We had provided with the greatest difficulty for 250. To provide suddenly for 500 more seemed at first sight impossible. But to give you one instance of the early work I will describe how it was done.

Among the offers which had been made to us was one from the Army and Navy Stores, proposing to lend us an empty shirt factory conveniently situated just opposite Victoria Station. It was in a perfectly sanitary condition, clean, with gas, light and water laid on, but stark empty. At eight o'clock on Wednesday evening we accepted the offer. Mrs. Walter Cave took direction in this particular act of energy, and I believe she was up all that night. The Army and Navy Stores let us have beds at cost price. The chairman of the Rowton Houses lent us crockery and linen. Willing help came from every side, and the result was achieved that before three on the following afternoon the shirt factory had been converted into a hostel where 250 beds were made up with clean sheets and pillow-cases, a kitchen was arranged downstairs with eight cooking-stoves, dining-tables were ready laid, and a hot dinner for several hundred people awaited the arrival of the

refugees. Our first batch of 250 arrived there that afternoon. We disposed of the others in different places, and from that day, though we continued to receive refugees in London at the rate of several hundreds per day, and were often at our wits' end what to do, not one who reached our hands was ever left without food and lodging.

The experience of this first week gave us the formation of the principal departments of the War Refugees' Committee. I do not propose now to detain you with any full description of our organisation. For anyone who is interested the details are recorded in the Blue-book issued by the Departmental Committee appointed by the President of the Local Government Board to consider and report on questions arising in connection with the reception and employment of the Belgian refugees in this country. I will indicate merely the framework of the machine which circumstances immediately brought into operation.

Our first need was obviously a Card Index and Correspondence Department. This department has since been placed under the very efficient management of Mr. Arthur Chadwick, and with the Cashier's Department, under our excellent cashier, Mr. Bourne, has completely rescued us from the reproaches of the first days.

We needed a Transport Department to meet refugees at the stations to convey them to and from the refuges. Under Mr. Henry Campbell, of the London General Omnibus Company, this department has become one of the most important and efficient branches of our practical organisation. Mr. Campbell's grip and comprehension of the work of the War Refugees' Committee is so complete that I believe if the whole Committee were swept away and he left standing the work would still be satisfactorily carried on.

Our next obvious need was an organised system of fitting the refugees into the offers of hospitality which were received for them. This has remained from the beginning the most complicated and difficult work we have had to do. A department, afterwards known as our Allocation Department, was organised at once under Lady Gladstone, Mrs. Alfred Lyttelton and Mrs. Gilbert Samuel, who have been assisted in the work by an army of willing volunteers. The work of this department, of which a beginning had been made in the Belgian Consulate Room even before the War Refugees' Committee came into existence, has since been carried on in four main divisions. There has been our Central Allocation Department, of which the direction has remained in the hands of Mrs. Gilbert Samuel. There has been a very important development of subsidiary branches in the Rink under Mrs. Alfred Lyttelton. There has been the allocation of the Belgian Consulate, also carried on at Aldwych under the direction of the Misses Rothschild and a group of helpers, and there has been the allocation of the Catholic Women's League, under the direction of Miss Streeter, working always in co-operation with Aldwych, but carried on from their own headquarters in Victoria Street. In addition to these there has been also the allocation, carried on independently of Aldwych, by the Jewish community, who from their own private offers have provided for upwards of 6,000 people. The Catholic ladies have also allocated upwards of 6,000. In the Misses Rothschilds' room at Aldwych, some 30,000 have been provided for. Our own two branches of allocation have since the beginning of the movement arranged for the placing of between 50,000 and 60,000 persons. In all, the War Refugees' Committee have found homes for 100,000 persons.

A department separate from the Allocation Department proper, but taking its rise in the same necessities, is the Department of Local Committees, which early in the movement formed themselves throughout the country for the better management of local offers of hospitality, while working in correspondence with Aldwych. This department at Aldwych has been from the beginning under the supervision of Lord Lytton, who has directed it with an ability and devotion for which the War Refugees' Committee have every reason to be grateful. The number of local committees with which his department maintains touch is now nearly 2,000.

To these departments one other of great importance was added in the first days. It was our Clothing Department, with headquarters at 23, Warwick Square. Here Lady Emmott, ably assisted by Lady MacDonnell and other devoted ladies, has been enabled by the generosity of the public to distribute nearly a million garments, including much-needed boots and shoes.

The creation of our different departments was, as I have said, immediately imposed upon us by the conditions of the problem with which we were dealing. The general work of direction and co-ordination, and the creation of new means of meeting each new necessity of the situation, had also to grow from the simple beginnings of the early days. It was soon found that it was desirable to place the management

under one direction, and it was decided to ask Lord Gladstone—who was prepared to give the time and devotion necessary to such a work—to accept a position which is, I suppose, equivalent to that usually held in a commercial company by the managing director. Mr. Morgan was at first associated in this direction, but found himself afterwards unable to devote the necessary time, and Lord Gladstone has from the beginning borne the brunt of the central work of the Committee. It is only in a later chapter, to which I shall have occasion to refer, that he has been assisted in a Management Committee by Lord Lytton and the Right Hon. W. H. Dickinson, M.P. Lord Gladstone's work has been no sinecure, and we all, if I may be permitted to say it, give ungrudging recognition to the absolute sincerity and unselfishness of purpose with which he has pursued it. We do not claim as a Committee—and I am sure Lord Gladstone would heartily agree with me—to have been perfectly organised or perfectly directed, or that our staff, amounting at one time to upwards of 500 devoted volunteers, have always perfectly understood or perfectly carried out the intentions and instructions of headquarters. We are willing to accept in a chastened spirit all reasonable criticism. The only claim we are concerned to make is that the War Refugees' Committee throughout has been a willing instrument. In ourselves we have been nothing. The power by which we have been worked has been the country. We are proud only to have been privileged to represent a movement which may claim to take its place in history as the consolation of a nation by a nation.

It is as a task of consolation that we have from the beginning conceived of our work. I regret to have detained you so long with a description of the machinery by which the work was done. I take you back now to the days when the first refugees, fleeing from the terror of fire and sword, began to reach our shores. These refugees were different from the refugees who are now arriving. They had actually borne the first onslaught of German fury. Men had seen their wives and daughters shot, and worse than shot, before their eyes. Fathers and mothers had seen their little children trampled to death under German feet. Old and young had alike been driven before the bayonet and placed as shields to protect the enemy from Belgian bullets. Some had been forced to dig graves, and even to bury men who were not yet dead. All had been smoked and burned out of their pillaged homes, holding themselves lucky if they were not forced back to be consumed in the funeral pyres of their domestic possessions. It has become the fashion now to cast doubt upon the authenticity of deeds fit only for the annals of the Middle Ages. Those of us who helped at that time nightly to receive the refugees as they arrived can never forget the tales of inconceivable horror which were poured into our ears, nor the convincing simplicity of narration which made it impossible to doubt their general truth. I remember the first refugee with whom I happened to speak about herself. It was not a horrible case—on the contrary, quite simple, but it brought home to me with a shock of realisation what was happening within an ordinary day's journey of London. It was only a mother feeding her child with a basin of bread and milk in one of our refuges. I asked her where she came from. She said, "Charleroi." "Then you have seen the fighting?" "Oh, yes; I carried him"—indicating the baby—"out under the German guns." It was nothing. She had had the luck to escape, but the contrast between the peacefulness of her actual occupation and her words brought home what she had escaped from. In the same refuge on a later day there was a man whose face was like the face of a tragic fate. He did not speak—he did not move. The ladies who were working in the refuge approached him for some time in vain. One reminded him that he had his wife while many had lost their wives, and at last he spoke. "Yes," he said, "I have my wife! But we had five children, and we have not one left. Four of the little ones were trampled to death under the feet of a German regiment, and my little girl, my eldest, fourteen years old, was given to the German soldiery, who misused her before my eyes. Afterwards they took her away with the regiment." And he fell back to the only thing he seemed able to say: "We had five children—we have not one left." The stories which we heard at that time daily and nightly, from not one alone, but from practically every refugee who reached us were such as surpass all imagination of horror and brutality. We heard them—we became in a sense accustomed to hearing them—but the details of many were such as I could not possibly repeat in a public assembly such as this. An observant friend who accompanied me one day to a refuge said, as we came out: "These people look as if they had all seen ghosts." They had seen ghosts! They had seen spectres of carnage, cruelty, lust and brutality—such evil spirits as, thank God, are not often let loose upon the face

of earth. You will readily understand that to us who were with them at that time, who heard these stories every day, no extenuation of German conduct which can ever be produced will efface the impression that these awful things were literally true. It was also abundantly evident that they were not the isolated acts of brutal or drunken individuals. Evidence was unanimous, and to our minds conclusive, that the crimes were committed in pursuance of a general order from above.

I will not hold your imagination in this atmosphere. Let it be placed to the credit of twentieth-century civilisation that the universal abhorrence aroused by the conduct of the German Army towards civilians was such as to force German authorities to a recognition of the mistake they had committed. Orders to terrorise the population were apparently withdrawn, and so far as we are aware the brutalities of the first weeks of the campaign have for the present ceased.

It was on August 24th that the War Refugees' Committee received its first refugees. Until September 9th they were received, as I have told you, in our own refuges, where we tried to make them as comfortable as we could. Some little difficulty and hesitation existed at first as to the question of facilitating the transport of refugees from Belgium. But this and all other doubt upon the matter was set at rest by the public offer of the hospitality of the nation which was made, as you will remember, by the Prime Minister in the House of Commons on September 9th. From that day the Government has stood behind the movement, and the War Refugees' Committee has worked in close and friendly relation with the Local Government Board.

The first chapter of Government intervention was to relieve the War Refugees' Committee of the expense and difficulty of providing refuges in London. The Government took the Alexandra Palace, and in that and other available public institutions it organised, under the Metropolitan Asylums Board and the Boards of Guardians, refuges which had a total capacity of about 6,000 persons. After the fall of Antwerp Earl's Court camp, with a further capacity of 4,000 persons, was added to the Government refuges. Up to the middle of September the War Refugees' Committee had had difficulty in receiving as many as 500 a day. Since that time, so far as the great majority, which consisted of working-class refugees, are concerned, the War Refugees' Committee has been relieved of anxiety. The first needs of shelter and food were supplied, and admirably supplied, by the Government refuges. I should like, in passing, to offer my tribute of praise to the splendid work done by the officials alike of the Metropolitan Asylums Board and the Boards of Guardians. I was for many weeks in close relation day and night with what was being done, and I can speak from personal observation of the devoted zeal, the kindness of heart, and the untiring industry with which the work of receiving, housing and feeding the refugees was carried out.

The organisation of the Alexandra Palace, where, at first, about 1,500 were received, may be taken as a sample of the rest. The Alexandra Palace, as you know, is a large glass building originally intended for public recreation and conveniently situated in its own grounds on a hill overlooking the north of London. Its central halls, with their merry-go-rounds and swing-boats, lent themselves readily to the reception of refugees, and in the early days visitors who went to condole with the victims of tragic misfortune were usually saluted with shouts of delight proceeding from children profiting, with all the unconsciousness of their age, by the unusual opportunities of enjoyment. The glass roofs of the building admitted sunshine to every corner. One of the central halls was converted into a great dining-room, where sufficient and comfortable meals were served with order and regularity. Beyond the dining-room there was a nursery and hospital, bright with white beds and flowers. Beyond the hospital a large hall has been converted into a bathroom with curtained cubicles, where upwards of 100 baths, fitted with hot and cold water, are at the disposal of the refugees. Another large room was used as a schoolroom and kindergarten for the children. The many rooms surrounding the central halls were converted into dormitories holding each from sixty to 100 beds. In one room the beds had pink coverings, in the next they had blue. Screens covered with chintz gave a certain privacy to groups of beds. Crucifixes were fixed upon the walls. There were lace curtains in the windows. A cinema theatre was converted into a chapel. Large rooms were set aside for workrooms and the distribution of clothing. These were the arrangements made before the fall of Antwerp for the general mass of refugees. Upstairs, in a more private wing of the building, there was accommodation, with a comfortably-furnished sitting-room and dining-room, for about 100

persons who might for any reason on their first arrival be distinguished from the ordinary crowd. Before the fall of Antwerp, since which period the rush of refugees has caused too great a pressure of over-crowding, there was a grace, almost a certain charm, in the arrangements.

Alexandra Palace was, of course, only one place. The spirit which dictated its organisation presided also over the organisation of the other refuges.

The first refugees arrived usually in a state of absolute destitution. Their constant prayer was that they might be immediately allowed to work and to earn for themselves some portion back of what they had lost. But an opinion was at that time held that no attempt should be made to obtain employment for these refugees in the ordinary labour market of the country, and the lavish hospitality which was offered to them encouraged the hope that they might be amply provided for by private beneficence during the continuance of the war.

The first work of the War Refugees' Committee when the refugees arrived in the Government refuges was, therefore, to supply them, as far as possible, with immediate necessaries. They needed everything. Besides the substantial necessaries of clothes and shoes, they wanted combs, brushes, soap, hairpins, bootlaces braces, needles, cotton, thimbles—everything that even the poorest find necessary in daily life. The men, of course, urgently needed tobacco, the women wanted knitting-needles and wool to knit. We did our best to supply all these, and among the small articles which at that time were distributed freely none were more eagerly accepted than rosaries. We gave them away by thousands. The exodus had been so sudden that they had apparently in many cases been left behind, and men and women alike among the first arrivals from the Walloon country seemed anxious to possess themselves of this usual accompaniment of prayer.

There are subjects about which one hesitates to speak in public, yet I would like just to place on record the impression we received from these first refugees of simple faith. They seemed themselves to realise, in the tragic extremity of their distress, that they had lost everything except their God, and I cannot easily convey the touching fervour of the prayers in the chapels of the refuges at which I once or twice incidentally assisted. Piety, courage, extraordinary fortitude, and overflowing heartfelt gratitude for all that was being done for them in England were the principal characteristics that enlisted our sympathy and admiration for our guests.

I know it may be said that the heroic note has not been consistently sustained. That is only to say that human nature remains human in all circumstances. And I would ask, if Oxford had suffered the fate of Louvain, if Canterbury had been destroyed instead of Rheims, if Manchester or Birmingham or Leeds had been bombarded and their population driven out homeless and penniless to foreign shores, do you believe that the whole exodus would have been an exodus of heroes? From the days of Israel onward some members of every great migration have been found to murmur and to cry for quails as well as manna in the desert. None grieve for this occasional backsliding more sincerely than the majority of the better-disposed Belgians themselves. I only wish to bear testimony to the other side, which I have myself seen and admired, of patient and even magnificent endurance.

The refugees were only supposed to remain in the London refuges for a period of three to five days at the outside. Once rested and refitted, it was the work of the War Refugees' Committee to pass them on to the permanent homes so cordially offered by the hospitality of the country. It was in these homes their real reception awaited them, and in these that was prepared for them by the kindness of individual English hearts the "haven where they would be." With what happened after they left our hands we had, of course, little or nothing to do. Everyone gave to his own guests according to the fullness of his means. We received many letters of enthusiastic thanks, expressing the content and joy of the refugees, but our business was only to organise the passing of the refugees from the London refuges to their homes.

The brunt of this work fell, of course, on our Allocation Department, which, as the pressure grew more and more acute through the months of September and October, was obliged steadily to increase its forces. It employed at one time upwards of 100 volunteers. The work of these ladies and gentlemen consisted in receiving from the Correspondence Department overnight cards upon which the offers of hospitality made to the Committee were indexed. With the cards they went on the following day into the refuges, and subsequently into hotels in which better-class refugees were housed, and their object was—acting with as much tact and sympathy as possible—to find from the information given on the cards the most suitable accommodation

for the many differing parties of refugees who presented themselves. At the beginning of the movement refugees had to be dealt with only at the rate of 100 or 200 per day. From the date of the public offer of national hospitality made by the Government the number increased steadily until, during the rush created by the fall of Antwerp, which marked the maximum pressure of the movement, it became necessary for the Allocation Department to deal with upwards of 2,000 persons every day. It is difficult for the public to realise the magnitude of the task thus performed. It involved not only the delicate personal decisions which had to be made by each individual allocator, but it carried with it all the complicated arrangements of registration, transport and warning of hosts. All four branches of the Allocation Department were at this time worked to their utmost.

The arrangements for transport of these separate branches fell upon the Transport Department. Every refugee who arrived from the Continent had to be met and taken to a refuge or a hotel. Every refugee who had left one of the refuges or a hotel to take up the hospitality allotted to him in the country had to be provided with a pass over the railway, had to be convoyed to the railway station, and his host had to be warned at what hour and at what station he was to be received. During the stress created by the fall of Antwerp—when upwards of 4,000 refugees arrived in one day by trainloads from the Continent, and as many as 2,000 had to be sent in small individual groups to different stations of the British Isles—a total of 6,000 had to be handled every day. No warning nor preparation could be given as to the numbers to be dealt with. While the crisis lasted they poured in day and night, taxing the energies of the whole organisation almost to breaking-point. Not only Transport and Allocation, but Clothing, Correspondence and Local Committees were heavily worked. They bore the strain. There was no breakdown. We were able to meet and deal with the crisis. It may readily be imagined that in work of a delicate nature accomplished under such pressure some mistakes were inevitable. But we worked with the consoling thought present to our minds that, if the public could have realised the conditions under which the work was done, it would have been surprised rather at the few than at the many errors into which we fell.

The fall of Antwerp brought us to a new chapter of our work, of which I would have much to say, but that I have already kept you longer than I would have wished. I must touch only as briefly as possible on the aspects of the questions which now present themselves.

The crisis lasted only a couple of weeks. The occupation of Ostend by the Germans on October 17th closed the Belgian coast and stopped the daily transport service. Since that time refugees have been only able to reach us by way of Holland, and though this country has continued to provide such facilities as are possible for their transit the figures of the daily arrivals have fallen considerably. The total for November was the lowest for any month since the beginning of the war. In December and January the numbers again mounted, giving a total of 12,000 for December and 14,000 for January. Refugees are still, notwithstanding the dangers of mines and submarines, and the prohibition of our blockade zone, arriving in numbers which are to be counted daily in three figures. But the rush is over. We are no longer working under the same conditions of pressure.

There are noticeable also some other remarkable differences. We are working now with a different class of refugee. The simple country folk of the first exodus have given place to the urban population of the great towns, and they come to us under different conditions. The early refugees had, as I have told you, suffered in their own persons all the worst horrors of war. Since the fall of Antwerp the flight has been rather—though not, of course, wholly—from "the wrath to come." Many refugees are fleeing from what they fear may happen rather than from what has actually happened. I speak chiefly for the moment of the working-classes. Many of those now coming have been attracted to this country by the accounts sent back in the first moments of relief and gratitude by the earlier refugees. In the refuges and hostels we saw many of the postcards written by the first refugees, and they represented this country and people as something so near Paradise and the angels that expectation based upon such description could hardly fail of disappointment. It need not, therefore, be a matter of surprise if some difference is observable between the attitude and tone of the refugees housed in the Government refuges to-day, and those with whom the same refuges were filled in the earlier stages of the movement.

The gradual development of the situation which has brought us a different class of refugee has also brought about a very important modification of opinion with regard to the conditions of their reception. It has been decided

that the employment of refugees instead of being deprecated should now be encouraged, and that instead of depending for subsistence on the hospitality of the country they should as far as possible be enabled to support themselves. A Government Committee has been appointed, as you know, under the chairmanship of Sir Ernest Hatch, to consider the conditions under which effect can be given to this new view of the situation. Belgian Labour Bureaus working in connection with the Central Labour Bureau have been established in the Government refuges, as also in the Rink at Aldwych. Recruiting bureaus have been established in the Government refuges, by means of which Belgians of military age are enabled to join their colours and return to the front at Flanders. By these agencies, in conjunction with the Government refuges and other forms of Government relief for urgent cases, the problem of the reception of working-class refugees may, I think, be said to have been met and disposed of.

The problem with which, since Christmas, we have been most acutely preoccupied is the problem of giving suitable help to the urgent needs of the propertied and professional classes. This is a class with which I have myself been thrown into close and constant touch, and the sorrows and difficulties of their position are very vivid to me. They have suffered, of course, horribly in regard to their material possessions, and the numbers increase daily of persons accustomed to live in the comfort of comparative affluence who are reduced to absolute penury. Such cases call for the sincerest sympathy and for practical help. Where only material possessions are concerned they do not, it must be recognised, make quite the same poignant appeal to elemental emotions that was made by the earlier refugees. But there is seldom a day in which some special case does not present itself. A day or two ago it was a case of a man of good position and once ample means, who had seen his wife and daughter shot by the Germans, and who came in search of some educational facilities for his little boy, the only member of the family now left to him. He was entirely penniless. The next day it was a manufacturer from Louvain who had shared in all the horrors attending the destruction of that town. His town house and his country house, with all that they contained, had been destroyed. He himself had been taken as a hostage by the Germans. He was three times blindfolded and ordered to be shot, and three times at the last moment the order was countermanded. He was beaten and spat upon. He was forced to march with other Belgians as a covering rank in front of the German advance. As he said, in very quietly relating these experiences: "It is doubted whether the Germans really used Belgian civilians as a covering-shield for their soldiers. I *know*, because they have used me. They put us in the front of their attack and bullets whistled between us as we advanced." But these things were all as nothing to the anguish of knowing that the soldiery which had marched him away in one direction had taken his wife away in another. It was impossible for him to know anything of her fate. After some days of marching in front of the German troops they came in touch with Belgian outposts. He was able to effect his escape, and he reached Antwerp through the Belgian lines. Still unable to obtain any news of his wife, he advertised in the hope that the news he gave of himself might reach her eyes. It did. After long delay the news was brought to him that she was alive, that she had escaped without serious injury from the Germans, and that she was in hiding in the neighbourhood of Louvain. To reach her he went on foot from Antwerp to Louvain, passing as he could through the German lines, hiding at times in ditches and swamps, wading through rivers to avoid the guarded roads. He told me the whole story with absolute calm, and only when he came to the climax of their meeting he suddenly broke down. "My wife," he said; "she had been living in the woods and fields with practically nothing to eat. She was a black skeleton, mere skin drawn over her bones." He could say no more. I didn't wish that he should. My business was merely to find him some means of living now that he and his wife were together in a place of safety. You can understand that, after hearing such a story, one's only feeling is that peace and security must somehow be assured.

In the early part of the movement such cases as these were provided for by private hospitality, and I come now to the greatest change of all which the movement has undergone. The movement of private hospitality, which has provided from first to last for a figure approaching to something like a quarter of a million refugees, has, as was to a certain extent inevitable, exhausted its first impulse. About Christmas-time we began to realise that the offers of hospitality had ceased. No fresh offers came, and hosts who had previously had Belgians in their houses wrote that they would shortly be needing this accommodation for other purposes. Our Allocation Department became a

department of reallocation. Gifts of clothing also sensibly diminished.

The funds of the War Refugees' Committee, which have been devoted to the relief of Belgians in England, have never been very great. Public contributions in money have been more usually given to the Belgian Relief Fund, which is entirely devoted to the relief of Belgians in Belgium. We have sometimes thought that the public did not clearly understand the distinction between the two Funds. Our wealth has consisted mainly in offers of hospitality and gifts in kind. When these began to cease we saw ourselves in danger of being unable to continue our work for want of means, and this situation introduced the present and latest chapter upon which we have entered.

I am sorry that I am not able at present to enter into a full explanation of schemes which are as yet imperfectly developed. A time will come when all information will be freely given. For our present purposes I will ask you only to take from me that we have been able to obtain, under certain conditions, a command of funds which permit us to give relief in cases of strict necessity. The money so available is not to be regarded as a substitute for, but as a supplement to, private generosity. It is, in certain cases, sufficient for the necessities of a working-man. The part of private generosity for better-class refugees still remains to bring the bare necessities of life up to the standard which the nation would wish to offer in such cases as those I have just now cited.

There are many obvious ways in which this can be done. Among them the most generally successful, so far, has been the organisation of large houses on the basis of gratuitous hotels. I have myself organised two or three such houses, notably one at Harrington House, in Kensington Palace Gardens, lent to me for the purpose by Lord Harrington; another at Hambro House in Princes Gate, lent by Mr. and Mrs. Eric Hambro; and a third in the King's Weigh House Parsonage, furnished and lent by the congregation of the King's Weigh House Chapel in Duke Street. In these three houses I have been able to receive about 120 refugees, who make with regard to them very charming expressions of content. What I have done has also been done by many others, and it has been thought that many people who are no longer able to entertain Belgian refugees in their own homes may be willing to contribute towards a system of organised hospitality under which suitable homes can be provided.

Another way of meeting the necessities of the class of refugees of whom we are now speaking is by paying the rent of furnished flats in which a very small grant is sometimes enough to render domestic life a possibility. Among the propertied and professional classes there are some who have still some small resources. For these the active brain of Mrs. Lyttelton has devised a scheme, which she is administering as a branch of the War Refugees' Committee, of flats furnished by the Committee and placed at the lowest possible prices at the service of the refugees. The scheme deserves a fuller description than I am able to give it. In all schemes of hospitable relief the national food supply, of which the gratuitous food is in great degree contributed as a free gift by our colonies, plays an important part.

I would like to have been able to do justice to other institutions for the assistance of refugees which have from the beginning of the movement developed as branches of the Allocation Department at Aldwych. I can only permit myself just to name the Education Department, under Lady Gladstone, Mr. Englehart (of Leper Island fame) and Father Christie, where, by a movement of educational hospitality offered by the public schools, the Catholic institutions and the universities of the country, free education has been provided for nearly two thousand Belgian young people. In this movement I am glad to be able to say that Eton, Oxford and Cambridge have handsomely done their part.

Another branch of activity which has been of the greatest value throughout the whole movement has been the Health Department, which, under Mrs. George Montagu, assisted by Miss Page, the daughter of the American Ambassador, has given help and relief to hundreds of cases of the sick and otherwise disabled.

All these and many other departments are still active at Aldwych. Lord Lytton, Lord Gladstone and Mr. Dickinson, who have been associated in a Management Committee since the opening of our latest chapter, have their time fully occupied. There is no sign of any diminution of work. Neither is there on our part any diminution of energy or of interest in the work which still remains to be done.

You may be inclined to think from the particulars which I have given you of this latest chapter of the work that the heroic moment of the movement has passed for England as well as for our guests. I would only venture to say that in heroic moments resolutions are conceived —it is for subsequent acts to give them shape.

In the details which I have given you we are simply working out the national resolution that the exiles now in our midst shall be cared for, helped and protected to the limits of our ability in this country, until the day dawns for them when they may return to the homes they love. We see no end, and we desire to see no end, to our exertions but the day of repatriation. Be that day near or far, we continue our work till it is reached, and we look with quiet confidence and absolute assurance to the public we know to give us the full support of its sympathy and its help.

DISCUSSION.

The Chairman (Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.), said the meeting had listened to a very moving address, and he thought he could assure Lady Lugard of every listener's heartfelt sympathy in all she had said. Lady Lugard was owed something more—a meed of admiration for her marvellous initiative which had set such a great organisation on foot. It had been very satisfactory to him to note that throughout the address Lady Lugard had preserved what he might call a due sense of perspective. She had never allowed mere sympathy to degenerate into anything like weak sentiment. There were many points in the address upon which no doubt various opinions might be expressed, but for his own part he would confine himself to one, namely, to the resolution of the Committee as to the employment of Belgians. He considered that a most wise resolution. He was quite sure that the Belgians themselves would prefer it. It was always pleasanter for a people to know that they were doing something useful than that they were merely living on hospitality. He had seen, at Earl's Court for instance, Belgian men who would be fairly capable of undertaking work in assisting to turn out munitions of war; and he knew there were many Belgian women who could teach English women a great deal in household matters, especially in the art of lace-making. He also thought that Lady Lugard had done well to make a brief reference to those terrible scenes which had been enacted at the beginning of the war—"Lest we forget." In England there was always a number of apologists. There were people always ready to apologise for anything. He believed, really, there were people who would apologise for the Devil himself. But no apology, to his mind, could ever cover those terrible iniquities of the first advance of the Germans into Belgium. It was just as well that now and then we should be reminded of them. To himself it was perfectly incomprehensible how the Germans, as we knew them before the war, could ever have lowered themselves to employ such methods, or to approve of them. One could imagine only that they were obsessed by the notion that, like the Children of Israel in old times, they had a Divine mission to perform, and that it was their business to regenerate the world by fire and sword. That seemed to be an ingrained belief in the mind of every German, and it was certainly a very curious physiological factor in the war, which hereafter might be subject to examination and explanation. He could only express a hope that the terrible sufferings of Belgium, and that "consolation of a nation by a nation" to which Lady Lugard had referred, might result in a much better and closer understanding of those brave and patient people; and that ultimately between ourselves and our nearest neighbours on the Continent—Belgium and France—there might arise a community of policy which would in the end tend to secure the peace of Europe.

Monsieur le Comte de Lalaing said, although he was bashful in taking the opportunity to say a word, yet it was too precious to let slip by. He was very happy to be able to congratulate, and to thank most deeply, Lady Lugard for all that she had said and done. What she had done for the Belgians would never be forgotten. She had been a friend of the first hour and a friend in the greatest need, and Belgium's gratitude would always be hers.

Mr. E. H. Rhodes said, as having taken some part in the work of the Committee under the Local Government Board, he was glad to have heard Lady Lugard explain the immensity and variousness of the work of the Committee. He had been speaking to a man from Lancashire the other day who had asked him to whom money from Lancashire could be sent. He told the gentleman to send it to the War Refugees' Committee, and the reply was, "Oh, I always understood they worked in London, and in London alone." That mistake seemed to be rather a general one, which was a great pity, and he suggested to the Committee whether they might not advertise a little more. The public had not realised the immensity of the work of the Committee.

Mr. F. M. Guedalla said, as one of the original members of the executive committee of the War Refugees' Committee, he thought he ought to bear some personal testimony to the inspiration and leadership which that Committee had enjoyed, and under which it had accomplished its work, at the hands of Lady Lugard. Doubtless it had been noted in the address that she had referred to the activity of everybody but herself and of every department other than her own. When he first met Lady Lugard in connection with the work it had been at Aldwych at nine o'clock in the morning. She would leave the office at about seven or eight at night to join those who were engaged in the transport department at the

reception of refugees at the different stations, which would mean very often working till one o'clock in the morning, in addition to which she was helping to organise the different hostels. The public could hardly be aware of the magnificent work which was being done by women. He had been amazed at the organising capacity of women at Aldwych. There were many complaints at first with regard to the work they were doing, but his own experience was that once the different women knew what were their departments, they kept to their departments and managed them admirably. One of the greatest organisers he had ever come across was Lady Emmott. With regard to subscriptions, he believed from first to last the Headquarters' Committee had received about £70,000. He could assure his hearers that they could do with another £100,000 if the public would only give it. It was very necessary not only to get repeated offers of hospitality, but above all it was necessary, almost for the first time in the Committee's existence, to get such subscriptions of money as would enable a woman like Lady Lugard and a man like Lord Gladstone to carry on the work as efficiently in the future as it had been carried on in the past.

On the motion of the CHAIRMAN a vote of thanks was accorded to Lady Lugard for her paper.

THE AGRICULTURAL AND MINERAL RESOURCES OF AFGHANISTAN.

Although a greater part of Afghanistan is more or less mountainous, and a good deal of the country is too dry and rocky for successful cultivation, yet there are many fertile plains and valleys which, with the occasional assistance of irrigation from small rivers or wells, yield very satisfactory crops of fruit, vegetables, and cereals. The fruit industry is, next to that of sheep, the source of greatest wealth to the country. In certain districts fruit, both in its fresh and preserved condition, forms the staple diet of a large part of the population throughout the year. A rapidly growing export trade in fresh and dried fruit exists with India. In dried fruit, especially raisins, which find a good market all over India, and pistachio nuts, melons, and certain kinds of grapes noted for their keeping qualities, there is a large trade through the Khyber Pass, but most of the fresh fruit is exported through Baluchistan, where transport through Kandahar (around which there are especially fine fruit gardens and orchards) and the Baluchistan railway terminus at New Chaman presents less difficulty. The value of the fruit and nuts exported through the Khyber Pass in 1911–1912 amounted to £95,000, and the value of such products exported through Baluchistan during 1912–1913 amounted to £129,000.

Fruit from Kandahar, together with that from Baluchistan itself, is marketed chiefly at New Chaman and at Quetta (the chief city of Baluchistan), and it is sufficiently large in amount to have necessitated a special daily fruit train to be run from Quetta to different cities in India during August, September, and October, 1913. According to the American Consul on special commercial service in India, the most famous Afghanistan fruit includes a sweet melon known as "sarda," which will easily keep in good condition for four or five months small seedless grapes, and dried raisins made from the same, pomegranates, pistachio nuts, and almonds. The sale of almonds except through agents of the Amir is forbidden. Fruit-farming is divided between orchard fruit, with which vegetable farming is usually combined, and those fruits which may be grown in fields on a large scale.

In the one class are apples, pears, almonds, peaches, apricots, plums, cherries, grapes, figs, quinces, pomegranates, and mulberries, in addition to walnuts, pistachio nuts, the edible pine, and rhubarb, which grow wild in the northern and eastern highlands. Vegetable produce, which also holds a high position in the export trade, includes most domestic vegetables; while of the uncultivated vegetable products, the castor-oil plant, the mustard, and sesame grow in great abundance. The fruit fields also produce several varieties of melons, including musk, water, and scented melons, and cucumbers and pumpkins. In the field of cereal production there are two harvests. One, reaped in summer, is the result of an autumn sowing and includes wheat, barley, and certain varieties of peas and beans.

The second harvest is gathered in autumn from a spring sowing, and embraces crops of rice, Indian corn, millet, arzun, and jowari, besides other grains of less importance. In addition to these cereals, crops of madder, tobacco, cotton, opium, hemp, clover, and lucerne are very generally cultivated. Clover and lucerne are produced for fodder, hemp for its intoxicating properties, and madder, tobacco, cotton, and opium for export. In relation to the other crops, wheat is the food of the people, barley and jowari are given to horses, and arzun and Indian corn are grown for culinary purposes. Among a few large landowners and fruit-growers, improved agricultural implements, garden tools, and pumps for irrigation are used, but in most cases the high transport cost makes their purchase prohibitive. The cultivation of turmeric and ginger, and horse-breeding are important. Silk is produced in large quantities at Kandahar, which is also the centre of other arts and crafts. The quality of Kandahar silk is capable of much improvement. The cocoons are small, of unequal size, and of different colours—yellow, white, and grey.

Except a gold-mine near Kandahar, in charge of Europeans, the mineral resources of Afghanistan are almost entirely undeveloped, but in different localities, gold, silver, iron ore, copper ore, lead, lead with antimony, silicate of zinc, sulphur, sal-ammoniac, gypsum, coal, and nitre are known to

exist. Rubies are occasionally found near the Oxus River. Rosaries are extensively manufactured at Kandahar from soft crystallised silicate of magnesia. This is quarried from a hill about thirty miles north-east of the city, where soapstone and antimony are also obtained in considerable quantities. The stone varies in colour from a light yellow to a bluish white, and is generally opaque. The most popular kind is straw-coloured and semi-transparent. A few specimens are of a mottled greenish colour, brown or nearly black; they are used for the same purposes as the lighter varieties. Rosaries and charms of various sorts are made for exportation to Mecca. The waste powder from the rosary industry is used as a remedy for heartburn.

THE CEMENT TRADE IN BRAZIL.

The quantity of cement imported by Brazil has increased very considerably of late years, and in 1913 was six times greater than in 1904.

The following figures, taken from a report of the Italian Legation at Rio de Janeiro to the Foreign Office at Rome, give some idea of the magnitude of this trade at the present time:—

Year.	Quintals.	Imports in English Tons.
1904	940,561	92,575
1910	2,641,706	260,010
1911	2,686,981	264,467
1912	3,670,315	364,251
1913	4,653,143	457,986

The average quantity imported annually during the last three years from different countries is given in order of their importance as follows:—

Country.	Weight in Quintals.	English Tons.	Per-centage.
Germany	1,319,313	129,853	44·00
Great Britain	871,810	85,808	29·06
Belgium	557,336	54,856	18·58
France	82,785	8,148	2·75
United States	72,746	7,160	2·42
Denmark	51,602	5,079	1·72
Austria-Hungary	25,661	2,526	0·82
Italy	466	46	0·04
Other Countries	17,918	1,761	0·61
	2,999,687	295,237	100·00

In this total of 2,999,687 tons Germany contributes nearly half, whilst Great Britain contributes more than one quarter. It is to be hoped that the cement manufacturers of England will take advantage of the present opportunity of extending their trade in Brazil and secure the first place.

The American brands, known as the "Lehig" and the "Atlas," in barrels weighing 150 kilogrammes (about 3 cwt.) gross, are in good demand at the present time in the Brazilian market. The prices average at Rio de Janeiro 2 dollars 10 cents per barrel (about 8*s.* 5*d.*). The cement imported from the United States enjoys a reduction of 20 per cent. off the Customs duty.

QUAY ACCOMMODATION AT PORT OF GENOA.

Notwithstanding the improvements that have been made during the last quarter of a century at the port of Genoa, the need for expansion in the facilities for discharging and embarking cargoes appears still to be making itself felt as much as ever.

In the opinion of some authorities the present congestion at this port is not so much due to the lack of a sufficient number of railway trucks as to the insufficient length of the quays, as compared with the tonnage of the goods handled.

In 1893, according to the report of a commission then appointed to inquire into the conditions of the port and its future, it was stated that the length of the quays and jetties was 6,500 metres (21,320 ft.), and the total tonnage handled (imported and exported) amounted annually to 3½ millions of metric tons, which gives a proportion of 538 tons per metre run (161·5 English tons per foot run) of quay.

This ratio, however, appears to have been too great, and in order to provide for the future development of the port during the period from 1893 to 1913, by the end of which it was estimated the tonnage might reach 6,350,000 tons annually, it was considered that at least 14,300 metres (46,904 ft.) run of quays would become necessary. This would give a ratio of 445 tons per metre (133·5 English tons per foot) between the length of quays and the goods handled, which, in the opinion of the commission, would be a fair proportion in order to ensure the economic working of the port.

During the twenty years which have elapsed since the last report was made, the tonnage handled every year at Genoa has more than doubled, reaching the figure of 7,427,272 tons in 1913, whilst the length of quays has only been increased about 30 per cent., being now 8,500 metres (27,880 ft.), which gives a proportion of 874 tons per metre (262·3 English tons per foot). This obviously must be a drawback to the economic working of the port, notwithstanding the greater facilities afforded by the employment of modern plant for the loading and unloading of ships, the erection of granaries and warehouses, etc.

The ratio is still more noticeable when it is considered that of this 8,500 metres of quay, 7,150 metres (23,482 ft.) are occupied for the landing of 6,215,000 tons, and 1,350 metres (4,428 ft.) for the shipping of 1,212,966 tons of merchandise. This gives a ratio of 869 tons per metre (260·6 English tons per foot) in the first and nearly 900 tons per metre (270 English tons per foot) in the second

INDUSTRIES AND COMMERCE OF RIO GRANDE DO SUL.

Rio Grande do Sul, the most southern of the Brazilian States, extends from lat. 27° S. to lat. 34° S. It enjoys a more temperate climate than that of any other part of the Union. To the north-west, the Uruguay River forms the natural frontier line with the Argentine Republic; the upper reaches of that river separates it from the sister State of Santa Catherina. It is bounded on the south by the South Atlantic Ocean, with a seaboard of about 400 English miles.

The interior of the country, however, is cut off from the sea coast for a distance of about 300 miles by two lagoons, called the laguna dos Patos and the laguna Mirim, which extend in a parallel direction to the shore, from which they are separated by a narrow strip of land. The lagoons are connected by a channel called the Rio Sao Gonçalo. Another channel, termed the Canal de Norte, offers the only means of access to the lagoons from the ocean. The town, which bears the same name as the State, with its little port, is situated on the banks of this channel, close to its junction with the laguna dos Patos, and about ten miles from the sea.

Until quite recently, the channel has been available only for small vessels, on account of the sandbanks by which it was obstructed, leaving a depth of only 4 metres (13 feet) available at low water. In 1906 a concession for the construction and working of a port on modern lines was granted to a French company, who have undertaken to deepen the channel to 10 metres (32 feet 9 inches) by the removal of upwards of 8 millions of cubic metres of sand, and so permit ships of large tonnage to enter the port, lie alongside the new quays which are being constructed, or to continue their voyage to Porto Alegre at the other end of the Patos lagoon, some 170 miles further north from the new port at Rio Grande do Sul.

Two breakwaters or piers, about 1¼ miles in length, are being constructed to form the entrance from the ocean. They are intended also to act as training walls to the current, and create sufficient scour in the channel to keep it free from accumulation of sand. According to the official returns published by the company, it seems that the trade of the port has considerably increased since the works have been commenced. In 1906 the 270,000 tons of goods exported or imported from the port had increased to 415,000 tons in 1910, to 439,000 tons in 1911; whilst the tonnage that crossed the bar for this and other destinations on the two lagoons, which amounted in 1906 to 467,000 tons, had increased to 590,000 tons and 668,000 tons in 1910 and 1911 respectively. About half a kilometre in length of new deep-water quays have been completed, with sidings and connections with the railway. This new port is about 375 miles from Monte Video.

The two principal industries of the State of Rio Grande do Sul are, like those of its neighbour Uruguay, pastoral and agricultural, and its products—jerked beef, hides, tobacco, beans and manioc—are for the greater part required for local consumption. The animal residues—hides, horns, and wool—are mainly exported.

The forests furnish a considerable quantity of timber for building purposes, which is exported principally to the districts on the Plate River. They also furnish many kinds of useful and beautiful woods, adapted for cabinet-making and other purposes.

The mineral resources are of comparatively little importance, although deposits of coal and auriferous quartz are worked on a small scale. Copper, wolfram, and other minerals are found also.

The manufacturing industry in 1911 was carried on in 1,557 establishments, and chiefly consisted of weaving, boot and shoe making, straw and felt hats, breweries, mineral waters, perfumery, and other products for local consumption.

According to the latest available statistics, the total value of the production of the country is estimated to be 82,000,000 milreis * (£5,125,000 sterling), of which 60,000,000 milreis (£3,750,000) is consumed locally, and 22,000,000 milreis (£1,375,000) exported. The chief exports are wool, hides, tallow, lard, horns and other animal residues, manioc, maté, etc. The principal countries to which these were exported previous to the war were Great Britain, Uruguay, Germany, Argentina, and Italy.

The imports are estimated at about half the value of the exports, and were chiefly cotton goods and general merchandise "made in Germany"; wines, oil, straw and other hats from Italy; motor-cars from England, Germany, and Italy.

Previous to the war, the steamers of various German lines of navigation touched at Rio Grande, as well as those belonging to Lloyd Brasiliere, Sociedade de Navigaçao, Anonyma Atlantica, and several French and Portuguese lines of steamers.

CUTCH IN MALAYA.

In consequence of the serious shortage of tanning extracts in English tanneries, the forest authorities of the Federated Malay States and Straits Settlements, says the Malay States Information Agency, have been carrying out investigations with a view to directing the attention of

* The milreis of Brazil = gold, 2*s.* 3*d.* English money, and about 1*s.* 3*d.* in paper currency.

British manufacturers to the possibilities of the development of an export trade in cutch from Malaya.

A reference to the trade statistics of the Straits Settlements shows that in 1913 there were imported into the ports of the Colony 2,163 tons of cutch valued at £30,337. Almost the whole of this valuable commodity came from Brunei, in the Island of Borneo. Of the total, less than a fourth was exported to the United Kingdom. About a half went to Germany, and the United States was the other large consumer, followed, a long way behind, by Denmark and Spain.

There seems to be no reason why the British manufacturers should not take the place hitherto occupied by the German and American users; still less reason for the Malay Peninsula not contributing to the world's requirements in this particular trade. The Conservator of Forests, Federated Malay States and Straits Settlements, has been carrying out the official investigations. He reports that there is an area of about 250 square miles of mangrove forest on the coast of the States of Perak and Selangor. There are nine predominant species of mangrove, and of these six are of value in the production of cutch. The whole forest is now a Government reserve forest, and is systematically worked for firewood only. No attempt has ever been made to work the mangrove bark for cutch. All the bark is at present a waste product, with the exception of a small quantity used locally for dyeing fishing nets and sails. The forests are intersected by innumerable creeks and streams, which render transport easy.

With the Governments of the Straits Settlements and Federated Malay States ready to encourage the growth of new industries, there would thus appear to be an opportunity, arising out of the British manufacturer's necessity, for someone to initiate and foster a trade in cutch from a portion of the Empire which has been coming more and more into public notice in recent years. Shipping facilities from the Straits to this country are regular, and not only could the present requirements of the Mother Country be satisfied, but there is now an excellent opportunity of taking up a comparatively undeveloped industry.

IRON AND STEEL INDUSTRIES IN THE FRENCH DEPARTMENTS OCCUPIED BY GERMAN TROOPS.

The following statistics, published in a German paper, appeared in the report of a conference of the Association of Steel Makers in Germany, lately held at Düsseldorf. They give some information respecting the present state of the iron and steel making industry in the North of France, in the departments now occupied by the Germans. According to the figures given, the percentage of the territory in the ten departments now in the hands of the Teutons is:—

The whole of the department of the Ardennes, or 100 per cent. of its area; Nord, 70 per cent.; Aisne, 55 per cent.; Meuse, 30 per cent.; Pas de Calais, 25 per cent.; Meurthe-et-Moselle, 25 per cent.; Somme, 16 per cent.; Marne, 12 per cent.; Oise, 10 per cent.; and the Vosges, 2 per cent. In all about 2 millions of hectares (7,720 square miles), or 3·7 per cent. of French soil, containing 3,255,000 inhabitants, or 8·2 per cent. of the entire population of France.

This comparatively small extent of the country, now under German rule, contains a very large number of the iron and steel works of France, of which the following percentages are in the hands of the enemy, namely: Manufactories of iron pipes 100 per cent., iron mines 90 per cent., iron girders 88·3 per cent., pig iron 85·7 per cent, coke 78·3 per cent., cast steel 76·9 per cent., steel rails 76·6 per cent., steel ingots 76 per cent., puddled steel 62·4 per cent., iron plates 63·2 per cent., iron wire 52·2 per cent.

It is also stated that the present annual output of steel "made in Germany" amounts to 10,800,000 tons—that is to say, 3,000,000 tons more than is produced annually in the United Kingdom.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Army Clothing.—It does not appear that our military preparations are suffering from want of cloth, although its conversion into uniforms may introduce passing difficulties. A clothier has been shown in London one three-acre floor piled to its utmost capacity with cloth, eight warehouses each 480 yards long similarly filled, and a one-acre room full of linings and trimmings. All this is additional to the great stocks in the stores in Manchester and Leeds, and to the extraordinary quantities in the hands of the clothing contractors. New supplies are being made pell-mell, and further contracts have lately been placed. Perhaps on these accounts there is no word of the commandeering of textile factories, as there is of engineering shops. Several groups of workpeople in the woollen and worsted trades have been placated by advances of wages or exceptional payments for overtime, and there has been no suggestion of "Ca' canny." The great run upon wool for military purposes has, of course, not been without its inconveniences to civil trade. Apart from the delays to goods on order, new civil business has been discouraged by the much enhanced cost of raw material, and by the premium put upon yarn by the unprecedented demands made on worsted spinners' facilities. Crossbred wool, such as is used for the uniforms of the rank and file, was not cheap at the outbreak of war, and is now appreciably more than 50 per cent. dearer. Merino wool, used for officers' uniforms, for much hosiery, and for soft dressgoods and cloths in general, is now as dear as when there was a famine in the article, despite that so much Continental

consumption has been cut off. Wool traders have a handy way of comparing the value of the one sort with the other, by calculating that one pound of merino buys so much crossbred. In extraordinary circumstances, one of merino tops has been known to buy virtually three of crossbred. Normally, 60's merino buys about two of 40's crossbred, and currently it buys about 1½; so deranged is the usual scale of comparative values.

The Use of Designs.—It is probably the general opinion among artists that manufacturers know nothing of art, and manufacturers are at no pains to disguise their belief that professed artists know nothing valuable about manufacturers' requirements. The estrangement between the pair robs discussions of art and industry of some vitality they might possess, were it possible to come closely to some common point. By way of clearing the air a little, Mr. W. T. Hesketh, head of the designs' department of the great Calico Printers' Association, gave a Manchester audience one fact about machine production. In particular he mentioned that from 40,000 to 50,000 new designs passed through his own hands in a year, all of them involving some exercise of the artistic faculties. These opportunities for the employment of artist-designers were put in contrast with those of the past, when printers' blocks were handed down from generation to generation. The number is manifestly large enough to include designs that are defensible upon the ground of taste, doubtless along with others that can best be condoned by the plea that somebody in the world wants them. In the eye of the manufacturer, the merit in any design resides in the orders that can be got for the goods. The multiplicity of designs is an uneconomical evil; the ideal would be to run the whole factory upon a single design and obtain a working profit by doing so. The ideal being unattainable it is requisite to provide such a profusion as will ensure steady and profitable work. Designs are selected with that view rather than for their gratuitous merits, and it is apparent, from experience everywhere, that the more austere their character the more limited their appeal; the shorter the yardage to a pattern, the more must be charged to cover the cost of manufacture. Such is human nature that long prices cannot be got for articles produced in more than very limited number. These are the conflicting circumstances within which the practical manufacturer works. Enlightened public demand might lift the artistic level of common goods, or—in company with economic changes—promote the production of what in effect are limited editions. Necessarily, the manufacturer with machines waiting has to deal with conditions as he finds them.

Co-operative Dyestuffs.—The old misunderstanding between artists and manufacturers has points of resemblance to the recently acute difference between scientists of high distinction and the textile manufacturers chargeable with the direction of the Government dye scheme. Chemists cannot be reproached for looking upon the occasion as one for the exercise of scientific virtuosity, or for regarding British Dyes, Ltd., entirely as a chemical industrial concern. The textile consumer of dyes sees in it a co-operative supply company, a means which is apparently the only—if not the best—one of obtaining colours that he indispensably wants. The consumer knows, in an unscientific way, what he at present wants rather better than any man of science can tell him, and the production of dyestuffs to meet the emergency is the first measure indicated. Perhaps it is not entirely by chance that, in the persons of Mr. Kenneth Lee and Mr. G. Garnett, the company has secured two directors who have paid quite an exceptional amount of attention to the use of fast dyes. The points are mentioned without prejudice to any valid claim that colour chemists may have had to fuller recognition. The English and the German prophecies of disaster awaiting this concern do not make its subsequent development any less interesting to follow. The difficulties of an uncharted voyage are naturally great, but it is worth remembering that there are certain points to steer by. The kinds, quantities, and prices of the colours first wanted are definitely known.

Foreign Debts.—Advances upon the security of outstanding foreign debts are still being received under the Treasury scheme by textile exporters and being paid over to their suppliers. It appears that the banks in some cases object to place other creditors in a better position than themselves, with the result that some such instalment as 50 per cent. is left owing. Exporters with large debts due from Germany and Austria are not sanguine about an early liquidation after the conclusion of peace. Some expect fully two years to pass before a settlement is effected of all the difficulties that may be raised. For six months the position of those yarn and other merchants whose business lay wholly in the hostile countries has been one of extreme anxiety. It is satisfactory to learn that some of them, by a quick adaptation to changed circumstances, are now doing nearly as much business at home and in neutral markets as ever they did in the countries that are closed to them.

Zeppelin Cloth.—A Manchester prosecution has elicited the fact that a cloth made in Chorley has been used hitherto for the ballonets of the Zeppelin airships. The fabric is a longcloth

or cambric exceptionally strong for its weight, and not signally different from such as may be used for embroidering upon, or conversion into, tracing cloth, or even into typewriter ribbons. Apparently the same cloth has been employed by airship constructors in this country. The manufacture of tracing cloth is quite an old British trade, and certainly of seventy years' standing. Typewriter ribbons may actually be prepared in this country, although a few years back they were not. The particularly fine and regular fabrics used for the ribbons were woven in Lancashire, slit up and impregnated with colouring matter abroad, and reimported in the finished state. It would seem that a good deal more of the similar cloth used for embroidery goes to St. Gall than to Nottingham, where there are, however, Schiffli machines.

Cloths and Skirts.—The lively discussion over the propriety of marked changes made in fashion amounts to a capital advertisement for those who are interested in the alteration of feminine silhouettes. Wider skirts, being garments requiring more cloth than narrower ones, might seem to be eminently to the interest of textile manufacturers as well. Actually the case is more complex than it may look. Notoriously, the coming of the hobble skirt was bad for particular classes of the weaving trade. The yardage required was reduced as a whole, dress fabrics of certain sorts were disqualified absolutely, undergarments of more than one kind were abolished, and all sorts of consequential damages were inflicted on the business in trimmings. The revolution involved some suffering, and the extinction of a certain number of private concerns; but there were some compensations. What was taken out of the length was put back more or less in the weight of the fabric used to make the skirt. New kinds of undergarments were introduced in place of the banished articles, and a general accommodation to circumstances was effected. The reversion to wider skirts involves the more or less gradual undoing of the whole process. For the present, the fuller garment does not require the substitution of cloth much lighter in weight than that taken recently; but once a beginning is made extremes are reached pretty quickly. The makers of the lighter cloths being different persons from the manufacturers of the heavier ones, the gain of the one is the loss of the other. It is not easy to arrive at a just balance, but so far as the present is concerned, it is reasonably apparent that the needs of manufacturers making coating, or the heavier cloths, are greater than those making light stuffs. What can be said is that the change involves a disturbance, and that it would be against all precedent were the needs or claims of manufacturers to have any influence at all in directing the course that such changes shall take. Equally with the protesting buyers and wearers of the skirt of the moment, the producers of cloths are the victims of independent powers.

CORRESPONDENCE.

PATENT LAW REFORM.

I hope I may be permitted to correct a slight inaccuracy in the report of Mr. J. W. Gordon's highly interesting paper on "Patent Law Reform," which was read at the meeting of the Society on Wednesday, March 10th.

In his references to the subject of technical education, Mr. Gordon speaks of the late Sir Bernhard Samuelson as Chairman of the Devonshire Commission. The Commission to which allusion is made was a Royal Commission appointed in 1881 by Mr. Mundella, when Mr. Gladstone was Prime Minister, and had no connection with the Duke of Devonshire.

Later on, in the year 1896 (not 1897), three members of that Commission, of whom I was one, together with their secretary, visited Germany—at their own initiative and at their own expense—in order to ascertain for themselves what progress had been made since 1884, the date of the publication of the Commissioners' report. On their return they drafted a report as to what they had seen, giving the conclusions at which they had arrived, and it was suggested that this report might be made in the form of a letter addressed to the late Duke of Devonshire, who was then President of the Council in Lord Salisbury's Government. This was done, and the letter, referred to by Mr. Gordon "as the second report of the Commission," was ordered to be printed and presented to both Houses of Parliament.

It is true, as stated, that the letter when published "gave rise to an important newspaper discussion upon the whole subject of technical education."

PHILIP MAGNUS.

Athenæum Club, March 14th.

NOTES ON BOOKS.

HISTORY OF THE STANDARD BANK OF SOUTH AFRICA, LTD. By George Thomas Amphlett. Glasgow. Printed at the University Press by Robert Maclehose & Co., Ltd.

The Standard Bank of British South Africa, Ltd., was established in 1862. At that period Cape Colony was a very different thing from the modern Union of South Africa. Steamship communication with England occupied over forty days, the cable was not dreamt of, and responsible government but vaguely mooted. Postage to England by the mail packets was 1*s*. per letter, and within the Cape it was 4*d*. per half-ounce.

The first railway from Cape Town to Wellington was under construction by a private company. The Colony had a territory of some 300,000 square miles, with a white population of about 300,000. The export trade of Cape Colony and Natal was little over £2,000,000, as compared with some £65,000,000 at the present time. The diamond fields and gold-mines had not yet been discovered; the ostrich-feather and mohair industries hardly existed, while the shipments of wool were little more than £1,225,000.

It may be said, then, that the history of the Standard Bank has been contemporaneous with the great and ever-increasing development of South Africa, for which, no doubt, it has been largely responsible. The beginnings were, naturally, on a comparatively small scale: the capital was, in the first instance, fixed at £1,000,000, in 10,000 shares of £100 each, with power to increase to £2,000,000. There was no difficulty in raising the amount asked for, and before the time for closing the share list had arrived applications had been made for 43,000 shares.

From its inception to the present the history of the bank has been a story of continuous development. It has, of course, had to face periods of depression, and during the South African War there was constant anxiety. For instance, on the outbreak of hostilities the greater number of the bank's staff at its eleven Transvaal branches were expelled from the country and sent away in cattle trucks, not even being permitted to take their personal luggage; and during the siege of Mafeking the bank's business had to be conducted underground in bomb-proof offices. At some of the branches the whole staff were in the trenches, and a considerable number found a place on the Roll of Honour.

The bank is now the owner of many fine buildings in various parts of South Africa, but some of the illustrations record the very humble origins from which they started. The original premises at Buluwayo were a small bell tent, in the dark interior of which are dimly visible a safe and desk. The staff consists of a bearded pioneer in unconventional costume, while the whole is guarded by an armed sentry. A pen-and-ink sketch shows a party of bank officers going off to open a Karoo branch: they are sitting in a couple of light Cape carts, and driving through the rain with a minimum of luggage.

This history is the work of the late Mr. George Thomas Amphlett, who entered the service of the Standard Bank in 1881, and retired from the post of assistant general manager last year. He only lived to enjoy his pension for a few months, but he has left behind an interesting record of a great banking institution.

Motion of Liquids. By Lieut.-Colonel R. de Villamil, R.E. (retired). 86 illustrations, 30 tables, 205 pp. London: E. & F. N. Spon, Ltd.

The author of this book has evidently read widely in the literature of this subject, and has attempted, in upwards of 200 pages, to give an account of his investigations, and "adds his own meditations." The work is dedicated to the two remarkable French military engineers, Dubuat and Duchemin, and this is significant, as a very large proportion of the volume is devoted to descriptions of the experiments of these pioneers. It may be said at once that in our opinion this is by far the most valuable part of the book, and students will be indebted to the author for bringing together in this volume an account of these experiments. After an introductory chapter, two chapters are devoted to a description and some discussion of the experiments of Duchemin, on the way a stream flows over immersed plates, inclined at varying angles to the direction of flow of the stream; diagrams are drawn showing how the stream lines distribute themselves, according to Duchemin, over the plates, and formulæ are quoted for the position on the plates of the "divide" or line dividing the stream lines moving in different directions. Dubuat's and Duchemin's Pitot tube experiments are also described. The next chapter describes similar experiments carried out before Duchemin's time. This is followed by two chapters on Relative Motion and Dubuat's Paradox, in which an attempt is made to show that when a body is at rest in a flowing stream the pressures behind the body are not the same as when the same body is moving at the same velocity in a liquid at rest. The author speaks of the head $\frac{v^2}{2g}$ being the theoretical head which a stream impinging on a body with a hole in it—a Pitot tube, for example—will support, and then shows that cases occur when the head supported is greater than $\frac{v^2}{2g}$. It is doubtful whether the author's method of treatment is sound. If the whole of the momentum of the stream lines approaching the hole were destroyed the head should be As a matter of fact, in the Pitot tube it is $\frac{v^2}{2g}$, and in other cases probably may be between $\frac{v^2}{2g}$ and $\frac{v^2}{g}$, but surely it only means in one case that the stream lines have more of their momentum in a given direction destroyed than in another, and there seems no reason whatever to continue to speak of the so-called Paradox, or to separate what the author calls "impact with shock" from "static liquid." The experiments and the results are, however, of interest. Chapters VIII. and IX. deal with water flowing in jets and the pressure on planes due to the impact of jets. Experiments are described and formulæ quoted. The treatment is not by any means complete. Chapter XII. deals briefly with the flow through mouthpieces, and the following chapter with the flow in rivers and canals. It is claimed that "Resistance in such channels is not caused by the liquid rubbing against their beds; it is almost entirely caused by the liquid changing shape and so forming eddies." This, of course, was the contention of Dubuat, Prony, and many other of the early

workers, who thus urged that the resistance was independent of the roughness of the surface of the channel, and that the slope of any channel could be expressed by a formula $i = Av + Bv^2$, A and B being constants. Following Newton, Dubuat, and others, the author contends that fluid resistance, when the fluid wets the surface, can always be divided into two parts - (1) due to viscosity, and (2) due to density—and that the resistance to bodies moving through water, or water moving over surfaces, can always be expressed by the form $R = Av + B v^2$. He scorns the attempt to express fluid resistances by logarithmic formulæ of the form $R = Av^n$ which, as he says, have been in favour. The accumulated evidence of the last fifty years shows, however, that the resistances of channels and boards moving through water are not independent of the nature of the surface, and though, as Loos has shown from an investigation of the experiments of a number of writers that for smooth pipes a general formula of the form $R = C\left(\frac{v}{d}\right)^n + B v^2$ expresses the fluid resistance of air, water and oil, the coefficients C and B only varying with temperature and density, with a very great degree of accuracy, the index n is certainly not unity.

Space forbids further discussion of the work. As already suggested, it is interesting as giving descriptions of experiments of the old workers, but as its conclusions are based upon a neglect of the enormous mass of data gathered during recent years, they must be accepted with considerable reservation.

F. C. Lea.

GENERAL NOTES.

The Imperial Institute.—In a General Note published under this heading in the *Journal* of March 5th (p. 350), it was stated, on the authority of the annual report on the work of the Institute for 1913, that it was hoped that a Technical Information Bureau would be established shortly. As a matter of fact, this Bureau was established in October last, and has therefore been at work already for five months. It is a special branch of the Scientific and Technical Research Department, and is staffed mainly by experts who have had the advantage of experience in the work of that department, which is carried on in communication with producers in the Colonies and with manufacturers and users of raw materials in this country. The present is a specially opportune moment for the formation of such a Bureau, since the paralysis of German and Austrian trade and industry opens up opportunities for the development of many industries in this country, and in the Colonies, which have hitherto been monopolised by Germany. Apart from its general activity, the Bureau is already playing a part in this work. Special circulars drawing attention to Colonial and Indian raw products of technical interest to British manufacturers will be issued as required, and distributed to all manufacturers likely to be interested. A number of these circulars are already available, dealing with such subjects as "New Markets for British, Colonial, and Indian Copra," "Wattle or Mimosa Bark for Tanning," and "The Production and Uses of Molybdenite." The circulars are carefully prepared from reliable sources, and contain a great deal of valuable information on the subjects with which they deal.

Shipbuilding in Italy.—The *Rivista Marittima* states that fifty new steamers have been added to the Italian mercantile marine during 1914. Of these eight were launched from Italian shipbuilding yards, and the other forty-two were either purchased or built abroad. Of the eight built in Italy, the largest, the "Lampo," of 6,296 gross tonnage, a tank steamer, was built for the Società Italo-Americana per il Petrolio, of Genoa. Three other steamers, of 5,604, 5,459, and 5,366 tons respectively, for the Società di Navigazione Italiana; two others, of 5,503 and 5,479 gross tons, for a private firm of shipowners; and two smaller vessels, the "Aosta," 562 tons, and "Zeta," of 104 tons, for the Società Commerciale di Navigazione Italiana, which are fitted with internal-combustion engines, were completed last year. On January 1st, 1914, nineteen steamships with an aggregate tonnage of 77,637, were on the stocks in Italy, and probably will be launched in the course of the present year.

Rubber Cultivation in British Guiana.—The area under Para rubber cultivation in British Guiana during the 1913-14 season was 4,018 acres—an increase of 879 acres over the preceding crop year. British Guiana lies within what may be termed the "rubber zone," and is adjacent to the home of the Para (Hevea) rubber tree. The plant is cultivated chiefly on the coast. The labour employed on the rubber estates is both negro and free East Indian. The major portion of the cultivated area has been opened up from the original forest and planted with Hevea alone, or with a mixture of Hevea and other crops, but some Hevea has been planted on previously existing plantations. Where rubber has been planted on land previously cleared for other crops, the cost of bringing it to maturity is low. Areas formerly devoted wholly to cacao, coffee, fruit trees, and sugar cane are being utilised for rubber, the existing crops being employed to cover some of the cost of bringing the rubber to maturity. Planting is mostly done by means of basket plants, but where seeds can be obtained in quantity for germination in a nursery on the property, this method is preferable. Various distances have been employed in planting, but the one now in common use is 20 by 20 ft., and is generally considered to give the best results.

SAMUEL MORSE AND THE SOCIETY OF ARTS.—The great reputation acquired by Morse for his telegraphic inventions has caused the fact to be overlooked that he was, at all events in his earlier years, much better known as an artist than as a man of science. The recent publication in America of his "Letters and Journals," edited by his son, Mr. E. L. Morse, records the fact that in 1811 he came to London with an American painter of note, Washington Allston, and that he was awarded a gold medal by the Society for a model of the "Dying Hercules." This award was made in 1813 for "an original cast of Dying Hercules." It was the lesser gold medal. Up to now the fact has never been noticed that the recipient of the award was the great American inventor. It was not until about 1832 that Morse turned his attention to the study of electricity, and not until after 1844 that telegraphs were working under his patents. He died in 1872.

BRYAN DONKIN FUND.—Applications for grants in aid of original research in mechanical engineering should be sent to the Council of the Institution of Mechanical Engineers before October 11th, 1915. The third award will be made in February, 1916, and the amount available will be about £34.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock: –

APRIL 14.—T. THORNE BAKER, "The Industrial Uses of Radium."

APRIL 21.—MORETON FREWEN, "The State and the Fisherman."

APRIL 28.—A. S. E. ACKERMANN, B.Sc., Assoc. M.Inst.C.E., "The Utilisation of Solar Energy."

MAY 5.—AUGUSTUS VERNON HARCOURT, D.C.L., LL.D., D.Sc., F.R.S., "On the Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate."

INDIAN SECTION.

Thursday afternoons:—

APRIL 15, at 5 p.m.—PERCEVAL LANDON, "Basra and the Shatt-ul-Arab." The RIGHT HON. EARL CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., will preside.

MAY 13, at 4.30 p.m.—SIR CHARLES H. ARMSTRONG, late Chairman, Bombay Chamber of Commerce, "Indian Trade and the War."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

MAY 4.—S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials." The HON. SIR GEORGE H. PERLEY, K.C.M.G., Acting High Commissioner for Canada, will preside.

Dates to be hereafter announced:—

C. H. SHERRILL, "Ancient Stained Glass."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

M. H. BAILLIE SCOTT, "House Building: Past and Present." Three Lectures.

Syllabus.

LECTURE III.—MARCH 29.—*Houses of the Present.* The average house of the craftsman period adorned the world—The average modern house disfigures the world—Normal modern building a disease rather than an art—The causes and cure of this disease—Difficulties of the architect—Building by-laws—The qualities of various types of houses discussed—An ideal house described.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. M. H. Baillie Scott, "House Building: Past and Present." (Lecture III.)

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. W. A. Pite, "King's College Hospital."

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Mr. R. Todhunter, "Two Notes on Questions of Office-Practice."

TUESDAY, MARCH 30...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Medicine, Royal Society of, 1, Wimpole-street, W., 5 p.m. Sir Almroth Wright, "The Septic Infection of Wounds."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. G. Avenell, "The Home and Haunts of William Cowper."

WEDNESDAY, MARCH 31...Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. G. C. Jones, "Estimation of Methyl Alcohol in presence of Ethyl Alcohol." 2. Mr. A. G. Levy, "Note on the determination of Niobium in presence of Tantalum, and some reactions of Tantalum Compounds." 3. Mr. T. Macara, "Estimation of Carbon Dioxide in Self-raising Flours and Baking Powder." 4. Dr. W. Versfeld, "Bromine Method of determining Phenol." 5. Miss E. C. V. Cornish and Mr. J. Golding, "A Method for the determination of Chlorine in Cheese."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m.

Electrical Engineers, Institution of, Victoria-embankment, W.C., 7.45 p.m. (Students' Section.) Mr. E. T. Driver, "Some Notes on High Tension Overhead Transmission Lines."

Correction.—For the name "Mr. Campbell M. Hunt," in the report of the discussion on p. 421, column 1, of the *Journal* of the 19th inst., read "Mr. Campbell M. Hunter."

Journal of the Royal Society of Arts.

No. 3,254. VOL. LXIII.

FRIDAY, APRIL 2, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

LECTURE BY M. PAUL LAMBOTTE.

M. Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, has offered to give a second lecture on "Constantin Meunier et les Sculpteurs Belges de son Temps," as a supplement to the Aldred Lecture which he delivered on "L'évolution de l'école Belge de Peinture (1830-1900)" on March 11th.

The lecture, which will be copiously illustrated with lantern-slides, will be given on Thursday, May 6th, at 4.30 p.m.

CANTOR LECTURES.

On Monday evening, March 29th, Mr. M. H. Baillie Scott delivered the third and final lecture of his course on "House Building: Past and Present."

On the motion of the Chairman, Mr. John Slater, F.R.I.B.A., a vote of thanks was accorded to Mr. Baillie Scott for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, March 18th, 1915; The Right Hon. Viscount Bryce, O.M., D.C.L., LL.D., F.R.S., in the chair.

The Chairman, in introducing the author of the paper, said that he was a distinguished officer, who had had much experience, not only in the direct work of soldiering but as an explorer. When he (Lord Bryce) had the honour of being Under-Secretary of State at the Foreign Office, nearly thirty years ago, Colonel Yate was wandering about in the least explored parts of the wild region that lay between Mesopotamia and Persia on the one side, and our Indian dominions on the other. He was then making explorations, which proved to be of great value, among the wild tribes of that country, and learning facts on his own initiative, which he was afterwards able to communicate to the proper quarter; and he (Lord Bryce) learnt even then what an adventurous spirit the author possessed, and how capable he was as an explorer. He, however, was not going to deal with those experiences: but he proposed to give some impression of the history and work of the Indian Army, and to pay a very deserved tribute to the gallantry which it had shown at many periods in its career, and which it was showing at the present time quite as brilliantly as ever upon the battlefields of Northern France.

The paper read was—

THE INDIAN ARMY.

By Lieut.-Colonel A. C. Yate, I.A. (Retired).

The Great War of 1914 has been a surprise or rather, an appalling shock, to civilisation. Austria's very ultimatum to Servia was an outrage on justice and on diplomatic precedent. When that ultimatum was delivered, Austria and Germany meant either the subjection of Servia, as a further stepping-stone towards Constantinople, or war. What they got was "War," and war it has been with a vengeance. Journalism revels in the head-word "Hun," and crams "Kultur" down the Teutonic throat. Cathedrals, universities, priceless libraries and art treasures, homes and human life—nothing has been sacred to Germany. The crews of defenceless merchantmen and lives in peaceful dwelling-places have met with no mercy. Hatred of the most venomous type animates all German action towards England. Happily, thanks to the cherub aloft who keeps watch and ward over civilian-run War Offices, and in the hour of danger commits them to

soldiers, our Navy and Army have held their own.* So far, we have given fully as good as we have got, and better. Now look back forty-five years. Our War Ministry then knelt down and worshipped Prussian military organisation. Our Army adopted a territorial system, and our cornets and ensigns became second or sub-lieutenants.† In this case we may well ask, "What is in a name?" Change of title leaves the British officer, the British soldier, and the British regiment what they were before. This war has proved it to the hilt, and never more nobly and gallantly, as the battlefields and trenches of Northern France, and, to the honour of our noble Navy, the icy waters of the North Sea and Falkland Islands know. Yet, almost up to the very day of the declaration of war, the farce of a prospective Anglo-German *rapprochement* was being rehearsed, and even our own infantry, when they faced the Germans on the battlefield, did so in the "double company" formation adopted from our enemies.

Just ten years have elapsed since Lord Kitchener first tried the double company in the Indian Army.‡ 1904 little thought that 1914 would see thousands of Indian troops thus reorganised operating under him, as War Minister, in Europe, Egypt, East Africa, Tsingtau and Turkish Arabia, while the Territorial Army of Great Britain garrisoned the East Indies and Egypt and fought all the world over.

For the brief space of about forty-five minutes I am to have the privilege of giving you my idea of the mould in which the Indian Army has been so shaped that it has become, as it is to-day, a World-power. My essay, to succeed, must fit into a nutshell. I once saw a Limerick kid glove—it should have been a Tipperary glove, but then, you know, it is *not* "a long, long way" from Limerick to Tipperary—I once saw a Limerick kid glove so fine that it fitted neatly into the half of a walnut-shell! I have tried to persuade my paper to model itself upon that kid glove.

The Charter of the East India Company was granted by Queen Elizabeth on December 31st, 1600. That Company had to face at once Dutch and Portuguese rivalry, and from 1660 onward French in addition. The merciless massacre in 1623 of the English at Amboyna—a Dutch settlement in the Molucca group—indicates the intensity of that rivalry. We know what were the methods of Drake, Hawkins, and Raleigh with our Spanish rivals in the Atlantic in the last half of the sixteenth century. Queen Elizabeth's charter enjoined on the East India Company that their trade should not interfere with the rights of any Christian Prince friendly to the British Crown who might already be in possession of territories in the East Indies. We have very early proof that the Company could not possibly, in its relations to and dealings with Europeans and Orientals, dispense with a naval and military protective force. Commander C. R. Low, writing to the *Times* about a year ago, tells us that the Indian Navy was raised in 1613, and for 250 (till 1863) years defended the Company's factories against Dutch, Portuguese, and Mahrattas, policed the waters of the Persian Gulf, and took part in wars in China, Burma, Java, Mauritius, Persia, New Zealand, Sind and Aden. On land it served at Mysore, Multan, and in the Mutiny. One of its earliest exploits was the capture in 1622, aided by the Persians on land, of the famous Portuguese emporium and fortress of Hormuz. The ruins of the Portuguese fortifications are still to be seen near Bandar Abbas. Milton pays a tribute to it in the well-known words, "The wealth of Ormuz and of Ind." The riches of Persia, Baghdad, Samarcand and Bokhara, Herat, Balkh and Kabul, found their way thither, and were exchanged for the products of Europe and the Indies.

By treaty in 1632 with the Shah of Persia and the King of Golconda the English company secured the trade between the Persian Gulf and Southern India, and specially the right of importing horses from the Gulf to the Coromandel coast. This is the origin of the Arab horse trade of to-day, which supplies our Indian cavalry with thousands of remounts annually, and so has its effect even on the fortunes of this great war. The resources of the Remount Department of the British Army are taxed to the utmost in providing horses for the mounted branches of the Home service. We may well be thankful that the Indian Army can horse

* The admirable article on "Civilian Control in War" in *Blackwood* for February, 1915, should be read, coupled with the letters of Lord Roberts and Sir Lonsdale Hale in the *Times* of December 2nd and 4th, 1912, on "The Art of Strategy" learnt in German Schools of Law and Philosophy.

† Professor Spenser Wilkinson writes, in the *Westminster Gazette*, March 18th, 1915: "The fate of the country is in the hands of the new second lieutenants. I think they are better men than their German counterparts. That is the basis of my hopes for victory."

‡ General Sir E. G. Barrow, Military Secretary at the India Office, wrote on March 15th, 1915: "The double-company system was experimentally started by me in 1892 in the Hong Kong Regiment, and either in 1898 or 1899 General Sir William Lockhart, then Commander-in-Chief in India, introduced it into the Indian Army." Lord Kitchener finally introduced it.—A. C. Y.

itself, be it with Arab, Australian, or country-bred.

By the beginning of the reign of Charles II. (1660), through whose marriage with an Infanta of Portugal England secured Bombay, the seats of government of the three great Indian Presidencies—Madras, Bengal, and Bombay—were practically settled. We may say that from that date all military and naval operations conducted by or for the East India Company were based on those three headquarter settlements. If I were for one moment to attempt to follow in detail the kaleidoscopic changes which, as history records, passed over the troops on which the safety of those settlements and the advancement and security of their trade depended, I should overstep the limits of my nutshell. We have already spoken of the Indian Navy. When the Home Government saw that some foreign power was seriously threatening our mercantile position in India, it sent out squadrons of the Royal Navy to protect our settlements and interests, and those squadrons generally escorted English troops. Between 1685 and 1780 I find the records of six such squadrons, commanded respectively by Admirals Nicholson, Boscawen, Johnstone, Watson, Pococke, and Hughes. With them came five or ten, or even, as with Boscawen, twelve Independent Companies, each consisting of four or five officers and about 100 rank and file, drawn from the King's troops. These Independent Companies were the English equivalent of the Infanterie de la Marine and the Légion Etrangère of the French. In 1758, when Wolfe and Amherst were driving the French out of Canada, a score or more of these Independent Companies were sent out to the American and West Indian Colonies. The first British battalion, or King's regiment, to land in India came out in 1754 with Admiral Watson, viz., the 39th, or 1st Dorsetshire, which still bears the motto, "Primus in Indis." It was Admiral Boscawen who backed up Stringer Lawrence, "the Father of the Indian Army," as he has been christened, and the first Commander-in-Chief in India. Lawrence reached Fort St. David in January, and Boscawen in August 1748, and then began the struggle with the great Frenchman Dupleix, which was continued by Clive, among several other able soldiers, such as Dalton,* Joseph Smith*; Forde, Eyre Coote, Kilpatrick and Caillaud, and by Admirals Watson and Pococke. The finest French sailor who ever brought a squadron to the East Indies was the Bailli de Suffren, a Knight of St. John of Jerusalem, who came out as the ally of Haidar Ali of Mysore.† Our Admiral, Sir Edward Hughes, was his match, but never scored a decisive victory over him.

During the century which preceded this vital struggle, immortalised in Macaulay's "Clive," grew up the nondescript army, European and native, with which the East India Company protected itself, its trade, its servants, and its possessions. Mr. John Fortescue, in a recent article in the *Times*, states specifically that the three original regiments of European infantry in India the Madras, Bengal, and Bombay Fusiliers (now the 1st Battalion Royal Dublin and the 1st and 2nd Battalions Royal Munster Fusiliers)—had their origin in Independent Companies. Clive did most of his fighting with Bengal and Madras troops, but a Bombay contingent was with him at Chandernagore and Plassey, and in the attack on the Angria pirate stronghold at Gheria; and in 1754, when Dupleix was pressing Madras very heavily, Bombay sent round to them 450 European infantry (100 being Swiss) and 300 Sepoys. The records of the first half of the eighteenth century show that the material of which these Independent Companies in the service of the East India Company was composed was, to use the words of the historians of the period: (1) "The sweepings of the English seaports," "the refuse of the vilest employments in London," and "the off-scourings of prisons and workhouses"; (2) Swiss mercenaries; and (3) Topasses, or half-castes of Portuguese extraction.‡ Companies of artillery, manned by English and Swiss, and troops of Dragoons (English) were also raised. Under Stringer Lawrence, Clive, Dalton, and their successors, the infantry companies were united in battalions for fighting.

* Romney's portrait of Captain John Dalton is in the possession of his great-grandson, Major-General J. C. Dalton, late R.A., and the memoir of him was written by another great-grandson, the late Mr. Charles Dalton, in his day a well-known writer on Army matters.

* Marlborough with his Dutch deputies, Wellington with his Portuguese Regency and Spanish Juntas, and the generals of the French Revolution with their "Representatives of the People," suffered no more than Colonel Joseph Smith with his Madras Council. *Vide* Fortescue's "History of the British Army," Book XI. Chapter VI.

† The Order of St. John of Jerusalem was instituted early in the twelfth century to oppose Islam. Its statutes forbade its Knights taking part in any national or international wars among the States of Christendom. Yet here we have a French Knight aiding a Mussulman against the English. Was it that Order's revenge for Henry VIII.'s suppression of the English Grand Priory in 1540? Or was the act a presage of the ruin that even then overhung the Order?

‡ I even find Caffres, as they called them, *alias* natives of Madagascar, fighting stubbornly at the assault of Nellore in 1757 under the leadership of a British officer.

and about 1760 permanent infantry battalions were formed. When, after the Mutiny, the Crown finally took over the forces of the Honourable East India Company, nine battalions were added to the infantry of the line, and the entire artillery of the three Presidencies was absorbed into the Royal Artillery. To-day the two scientific corps, artillery and engineers, are represented in the Indian Army by three powerful and efficient corps of sappers and miners, and by twelve admirably trained and organised mountain batteries. I find no evidence that European cavalry, even in single troops, were to be found after 1740 in the service of the East India Company, until the time came when His Majesty's regiments of horse were sent out from England.

It has been said that Dupleix taught the English how to conquer India with its own inhabitants. Let it suffice here to say that from about 1745 onwards both English and French commanders took the field with small bodies of European troops supported by some thousands of Sepoys, and occasionally by the ill-disciplined rabble in the service of native princes. Mr. S. C. Hill has just brought out "Yusuf Khan, the First Indian Commandant," which gives us some insight into the formation of the early Indian native regiments. They had English sergeants, it seems, but no English officers till they went on active service. Yusuf Khan, the Subadar of Nellore, was a most able man, and from 1750 to 1762 the trusted ally of Lawrence, Clive, and Dalton. Injudicious treatment then made him revolt, and the Nawab of Arcot, in 1764, was allowed to put him to death.*

Some twenty-six years ago, when the abolition of Presidential armies was already foreshadowed, the Council of the Royal United Service Institution were advised that it would be well, before the last of the old officers of "John Company" had passed away, to have some record of the origin and formation of the three Presidential armies. Major-Generals J. J. H. Gordon, J. Michael, and W. E. Macleod lectured, in March 1888, at the Institution, each on his own Presidency. Vol. XXXII. of the Institution Journal reprints the lectures and the instructive discussions that followed, in which Sir Henry Havelock-Allan, Sir John Watson, Sir William Olpherts, Sir Robert Hume, and Sir Peter Lumsden, among other distinguished officers of the Indian Army, took part. There is a wealth of knowledge there which can only be referred to by me.

Within a few years after these lectures were delivered Presidential armies ceased to exist. Our Indian Army was formed under one Commander-in-Chief, divided at first into four commands—Punjab, Bengal, Madras, and Bombay—and later, as it is to-day, into ten divisions and the Aden Brigade, which are grouped half in the "Northern" and half in the "Southern Army."

It was unquestionably the rivalry of the French that gave an impetus to the improved organisation both of European and native troops in India. As long as the East India Company had only to deal with the princes and people of the country, moderate armaments sufficed. But when such men as Labourdonnais, Dupleix, Lally, and Bussy, supported by French naval forces, came upon the scene, the contest became one of life or death for the Company, and for English prestige in the East. Not only did the English and French leaders realise that every nerve must be strained to create and maintain a fighting force capable of crushing the adversary, but the princes of India themselves saw that, in order to cope with each other and with foreigners, they must have troops trained and organised on the European model. They did, in fact, in the eighteenth and early nineteenth century, what the Japanese began to do after the Meiji. The Nizam of the Deccan, the great Rajput and Mahratta Chiefs, the Peishwa, the Holkars and the Scindiahs, Haidar Ali and Tippoo Sultan of Mysore, and the Sikh Maharaja Ranjit Singh, employed European adventurers of all nationalities to train their armies. The names of Boigne, Reinhardt, Perron, George Thomas, Michel Raymond, Avitabile, Van Cortlandt, Allard, Ventura and Filose, among many others, are well known to students of Indian military history, and to these we may add two names which mark the origin of the 1st, 2nd, and

* Lieut.-Colonel Forde, of the 39th Foot, who on certain conditions gave up the King's service and entered that of the Honourable East India Company, is an instance of a fine soldier sacrificed to what the Company would term "expediency." Clive was so impressed with Forde's pluck and skill in capturing Masulipatam and its French garrison with a force numerically inferior to that garrison, that he brought it to notice in most special terms. The Memoir of Forde, written by a descendant, tells the story of Captain Yorke at the storming of Masulipatam, carrying a breach and several bastions at the head of his English company, and then suddenly left alone, his men having bolted in a panic, with two little native drummer-boys "beating the Grenadier march." Going back, he rallied his men, and brought them on again, but in the rush on the next bastion the two little drummer-boys, who had stood by him when his men fled, were both shot dead; while Yorke himself fell with a ball in each thigh, and sixteen soldiers.

3rd Regiments of Indian Cavalry to-day, viz., Col. James Skinner and Col. William Linnaeus Gardner. Mr. Keene's "Hindustan Under Free Lances" tells the story of these remarkable leaders of *condottieri*, the lives of some of whom embody a romance which has left its mark even to this day.

I will touch briefly on the story of three, Gardner, Boigne, and Reinhardt, respectively of English, French, and German (believed born near Trèves, but entered French army) race. William Linnaeus Gardner descended from an Irish line of soldiers (his grandfather having commanded the 11th Dragoons, and his great-grandfather helped to defend Derry), and was himself a captain in the 30th Foot. His uncle, Alan, was a very distinguished naval officer, and in 1800 was created Baron Gardner. William Linnaeus, when he took service with Holkar, married a daughter of the Nawab of Cambay. His grandson married a reputed grand-daughter of the last King of Delhi, and therefore a descendant of the great Moghul line of Tamerlane, Baber, Akbar, and Aurangzeb. The succession to the Barony of Gardner has since 1883 been in dispute, and one of the claimants is the direct descendant of William Linnaeus Gardner, and on the maternal side of two Indian princesses.

Turning to Boigne, we find that he came home with a fortune towards the end of the eighteenth century and married Adèle, the penniless daughter of the Marquis d'Osmond, a French Royalist refugee resident in England. The beautiful Comtesse de Boigne, the pages of whose "Mémoires" so many of us have, at least, skimmed, found the rich and now titled but elderly husband a dull companion, and left him to lead her own independent life. The Comte de Boigne went to reside at Chambéry, in Savoy, where his memory is still revered for his good works. Colonel Tod, of "Rajasthan" fame, visited de Boigne there in 1826, four years before his (de Boigne's) death.

The Reinhardt romance is almost the strangest of the three. "Sombre," as Reinhardt was commonly called, died in 1778, but his relict, the famous Begum Sumroo, with her stepson, settled at Sardhana, near Meerut, and maintained there the Sardhana Brigade, consisting of five battalions, forty guns, and a regiment of horse, containing 300 Europeans, at the head of which she herself took the field, finally receiving the Sardhana property as a fief from the East India Company. When she died, in 1836, she left all her property to her step-grandson, David Ochterlony Dyce Sombre.* He married a daughter of the third Viscount St. Vincent, and died leaving her his property. She married *en secondes noces* the third Baron Forester, and left to the Forester family a very large sum of money (£400,000, it is said) for the erection and maintenance of hospitals for the poor of certain Shropshire districts. With this fund are maintained two hospitals and a convalescent home, which are, I hear, now being used for the treatment of the sick and wounded of this war. When we look back on the chequered careers of Walter Reinhardt and the Begum Sumroo, it is curious to think that they were unwittingly working for the future welfare of the British soldier in this war.

The century which preceded the admission to the ranks of the East India Company's Army of the Pathan, Sikh, Punjabi and Baluch, covers a broad field of warfare of the most momentous character, on one or two incidents only of which I can touch. After our struggles with the French and the formidable power of Haidar Ali and Tippoo Sultan and our earlier wars with the Mahrattas were past,† came the expedition under Sir David Baird to Egypt and the very difficult march across the desert from Kosseir to Cairo. David Baird was among the prisoners made by Haidar Ali in 1780, the tale of whose sufferings at Seringapatam makes a man shudder as he reads it. There is a story afloat that when Mrs. Baird, David's mother, heard that the prisoners were chained two and two, she exclaimed, "Heaven help the chiel that's chained to oor Davie!" That speaks volumes

* I find that Sir David Ochterlony was, in his later years, appointed Agent to the Governor-General at Karnal, then the North-West Frontier Station of British territory in India. The Begum at Sardhana would be in his Agency, and it is not impossible that Sir David might be godfather to the young Dyce Sombre.

† We hardly, perhaps, realise to-day the hostile forces with which the Marquess Wellesley had to cope at the time when Tippoo Sultan's power was at its zenith. Lord Brougham, in his "Statesmen of the Time of George III.," Vol. III. pp. 279-285, defines them well. Tippoo Sultan had the support of the Government of France, and, in prospective, of 14,000 troops in the service of the Nizam, trained by the Frenchman, Michel Raymond. Moreover, Shah Zaman, of Kabul, was ready—following the stereotyped route *viâ* Peshawur, Lahore, and Karnal, and passing the sites of the famous battlefields of Panipat and Thanesar, the route of Alexander, Mahmud, Taimur, Baber, and Nadir Shah—to march on Delhi. To break up this possible coalition, Tippoo and the Mahrattas had to be crushed or overawed. In the school of these wars the Marquess's brother, Colonel Arthur Wellesley (the future Great Duke), learnt some of his early lessons, and won the fame that recommended him for the command in Spain.

for "oor Davie's" boyhood, and foreshadows his fine future. He was terribly wounded in the action in which he and many others were made prisoners, and when Haidar Ali's brutal myrmidons wanted to put irons on poor Baird, despite his wounds, Captain Lucas sprang forward and said he would wear two sets himself rather than that Baird should be fettered. Try a weight of 9 lbs., the weight of the Seringapatam fetter, round your feet for a few hours, and then think how you would like 18 lbs.* This terrible imprisonment lasted four years. In 1799 Sir David Baird led the storming party of 4,000 at the second siege of Seringapatam, and had his revenge. His expedition to Egypt followed in 1801. When we recollect that in 1885, despite all the preparations made for a railway from Suakin to Berber, Lord Wolseley declined to face that route for the relief of Gordon, we will appreciate the ability of Baird and the merit of the troops under his command, some of them being Sepoy regiments from Madras and Bombay, who, after a long sea voyage from Bombay to Kosseir, performed the onward march to Cairo without loss or mishap. On the other hand, native troops have on occasion proved "kittle cattle." The Vellore mutiny of 1806 is a terrible story, the redeeming feature of which was the gallantry of Colonel Gillespie, the same fine soldier who, in 1815, as Sir Rollo Gillespie, died nobly leading his men against the Gurkhas in the passes of Nepal.

A poet whom the King has recently delighted to honour, Sir Henry Newbolt, has told us in his attractive verse, which seems by its very *élan* to carry us onward on the airy wings of its loosely woven narrative, the stories of David Baird and Rollo Gillespie. We grasp the spirit and force of Newbolt's verse best when we know something of his story beforehand. Thus he writes of Baird as a prisoner :—

"Baird was bonny and Baird was young,
His heart was strong as steel,
But life and death in the balance hung,
For his wounds were ill to heal.
That was the hour when Lucas first
Leapt to his long renown;

Then Lucas speaks :—

"'Tell ye the lord to whom ye crouch,
His fetters bite their fill;
To save your oath I'll wear them both
And step the lighter still.'"

Baird stormed Seringapatam in 1799, and in Newbolt's verse thus dismisses his hostages, Tippoo Sultan's sons :—

"'For all the wrong your father wrought
Your father's sons are free;
Where Lucas lay, no tongue shall say
That Mercy bound not me.'"*

Captain Lucas died, after two years of captivity, in July 1782. We owe Sir Henry Newbolt a debt of gratitude for reviving Lucas's noble memory. The spirit of Captain Oates was in him.

On July 10th, 1806,† at 2 a.m., 1,500 native troops, many of whom had been in the old Mysore army, mutinied and attacked 400 of the 69th Foot, who held Vellore Fort, their wives and children being there with them. At 6 a.m. Colonel Gillespie, at Arcot, fourteen miles off, got news of this. He was then in command of the 19th Light Dragoons. Sir Henry Newbolt tells the story thus. Gillespie speaks :—

"'Trumpeter, sound for the Light Dragoons,
Sound to saddle and spur,' he said.
'He that is ready may ride with me,
And he that can may ride ahead.'

* * * * *

"Alone he came to false Vellore,
The walls were lined, the gates were barred.

* * * * *

"'A rope! a rope!' Gillespie cried.
They bound their belts to serve his need.

* * * * *

"And lightly swung and rightly swung
Over the gate Gillespie came.

"He dressed the line, he led the charge,
They swept the wall like a stream in spate,
And roaring over the roar they heard
The galloper guns that burst the gate.

"Fierce and fain, fierce and fain,
The troopers rode the reeking flight.
The very stones remember still
The end of them that stab by night."

* When I was in command, some fifteen years ago, at Chaman (railway terminus sixty miles from Kandahar), an Hazara ex-sepoy arrived there from Kabul. He had been arrested and put in irons for eight months. He escaped, and, traversing the Ghilzai country, reached Chaman. His leg was suppurating, the bone having been eaten into by the fetter. We tended him for some months in our hospital and he improved. I was then *ordered* to send him to the civil hospital, where in less than a month he died.

* At the St. John Ambulance and Red Cross sale to be held at Christie's in April, the sword of Tippoo Sultan, taken by Colonel the Hon. Arthur Wellesley in 1799, is to be sold. The Duchess of Wellington has received it from Mrs. Matthews, of Portumna, to whose ancestor the great Duke's brother had given it.

† Gillespie was to have dined with Colonel Fancourt at Vellore on the evening of the 9th. Urgent Government business obliged him to forego this engagement. This probably saved both him and the Vellore garrison.

Six hundred of the mutineers were killed on the spot, and most of the remainder were captured. The bulk of the 69th Foot and their women and children were saved; but in officers the 69th lost very heavily, though to Sir Henry Newbolt's version of that point we must, I think, allow some measure of poet's license.*

Just a year before this moving incident Lord Lake had made a stern effort to take Bhartpur. Four attacks were made and repulsed, the 12th Bengal Native Infantry having in three of those attacks successfully planted their colours on the top of the breach or rampart, but by not being supported had to withdraw.

The 12th Bengal Native Infantry has passed away. Lake's siege of Bhartpur is borne on no colours or list of regimental honours, as the siege resulted in failure. The "Bhartpur" that is commemorated is the successful siege of 1826, under Lord Combermere. In 1825 a deputation from Leadenhall Street waited on the Great Duke, and said, "We want a Chief who will take Bhartpur." Said the Duke, "Lord Combermere's your man." Said the deputation, "We doubt his genius for a siege." "Bless his genius," said the Duke, "I tell you, Combermere's the man." The directors took him, and within the year he took Bhartpur. We may run through innumerable engagements and sieges, Assaye, Kirkee, Koregaum, Laswari, Dieg, Asirgarh, Mahidpur,* and so on, till we come down to the battles of Maharajpore and Punniar, on December 29th, 1843, where Sir Hugh Gough and General Grey severally defeated Scindia's forces, numbering about 30,000 men competently trained and disciplined by Christian officers of European descent. Sir Charles Napier and Sir Harry Smith in their correspondence present us with a humorous picture of Gough's army so taken by surprise that Ladies Gough and Smith were seen careering about on an elephant in the thick of the bullets. Writes Sir Charles to Sir Harry: "How came the ladies to be in the fight? I suppose you all wanted to be rid of your wives? Well, there is something in that; but I wonder the women stand so atrocious an attempt. Poor things! Well, I dare say they too had their hopes!" Can we understand the animosity of Lord Dalhousie and Outram and Jacob against the genial old gentleman who could write such pleasant and kindly chaff? But Sir Charles Napier could be a Tartar.

I must lead you now to a scene, a scene of stern fight and death, with which Sir Charles was himself in part associated. The scene is in or about 1846 in the Cutchee Hills, on the border of the Marri and Bugti countries, which lie between Upper Sind and the Pishin plateau. Napier's biographers tell how an English sergeant and ten English soldiers of the 13th (Somerset) Light Infantry, Jelalabad men, veterans of Sale and Dennie, misunderstanding their orders, pushed on up a steep ascent till they were met at the top by eighty hillmen, Bugtis, Jakranis, or Dumkis, and fought with them to the death. The eleven all fell, having killed seventeen hillmen. The Baluch survivors tied a red thread on both wrists of each Somerset man and left them. Thus they were found. Sir William Napier adds: "They had done the same before (in 1840 or 1841) to the heroic Clarke, whose personal prowess and intrepidity had been remarkable." I must make the story short. Seventy years ago, in the Indian Army, "Kāhun Brown," *alias* Captain Lewis Brown, 5th Bombay Native Infantry, was a name familiar to all. He held Kāhun, the principal Marri village, for several months with 150 men, hemmed in by

* The following passage in "The Mahratta and Pindaree Campaign of 1817-18-19," by "Carnaticus" (Captain Marshall Clarke), came to my notice recently. The story is given by Captain Clarke to illustrate the evil resulting from the ignorance of the native colloquials then almost universal among the officers of the King's Service. "Had Lieut.-Colonel Fancourt, who commanded at Vellore in 1806, understood the native language, he might have profited by the information of a Seapoy who discovered the plot to him; but the Colonel and his family being totally ignorant of the language, he was obliged to have recourse to a Subahdar implicated himself in the conspiracy, and who interpreted the Seapoy's report into a piece of merriment, adding of himself that the Seapoy had been mad for years. The succeeding evening brought about the well-known calamities of the 21st July, 1806" (p. 320). Major-General Sir R. R. Gillespie was killed in 1815, in the attack on the Gurkha stockade at Kalunga. His Memoir, dedicated to H.R.H. the Prince by "the Author" (anonymous), appeared in 1816. The only copy I know is in the India Office library. To know what manner of man Gillespie was the Memoir should be read. Three noted men in India are said to have speared tigers on horseback, viz., James Skinner, Rollo Gillespie, and James Outram. "On the racecourse at Bangalore Gillespie attacked and speared a royal tiger of the largest size and most furious description. The horse which he rode on this occasion was a high-bred Arabian, and the only one that could be brought to face the tiger. This fine animal (presumably the horse, not the tiger, is meant) is now, or was lately, in England, having been sent home by the colonel as a present to His Royal Highness the Duke of York."—Gillespie's "Memoir," p. 111.

* "Carnaticus" (Captain Marshall Clarke), writing in 1820, says that at the time of the battle of Mahidpur (December 21st, 1817) the British force under Sir T. Hislop and Sir John Malcolm, amounting to 8,000 fighting-men, was accompanied by *two hundred thousand* camp-followers. About 1840 Sir Charles Napier in Sind put his foot down, reduced his own baggage to four camels, and gave subalterns one each. Even the Political Officer kept up his hundreds of camels for his preposterous camp.

the hillmen. At last he told the Marris that if they did not at once let him out with all the honours of war, he would just stay where he was for another six months. This so worked upon the Marris, whether upon their fears or their sense of humour I leave you to judge, that they agreed that he should march out with all the honours of war, and they faithfully kept their word. The Commander-in-Chief ordered the account of the defence of Kāhun to be read out to every regiment in the Bombay army (this was in 1841), and the Government of India made "Kāhun Brown" —there was neither V.C. nor D.S.O. in those days—a "Political Officer."* He became President at Baroda and died there from the kick of a horse. Baroda is somewhat fatal to Residents. Diamond dust is reported to have threatened to end the career of one Resident.

Walpole Clarke was a young cavalry officer who, with his troop, had escorted Captain Brown to Kāhun, and then went back for supplies. The Baluchis, in hundreds, attacked his small escort and annihilated them. Clarke fought and died most gallantly, so gallantly, that the Baluchis honoured him as they honoured the Somersets. Sir Francis Doyle thus concludes the Somerset men's story in his poem "The Red Thread of Honour":—

The Baluch chief speaks:—

"'Enough!' he shouted fiercely,
'Doomed though they be to hell,
Bind fast the crimson trophy
Round *both* wrists! Bind it well!'

"Then all those gallant robbers
Shouted a stern 'Amen!'
They raised the slaughtered sergeant,
They raised his mangled ten.

"And when we found their bodies
Left bleaching in the wind,
Around *both* wrists in glory
That crimson thread was twined."

—*The Red Thread of Honour.*

* At that period many a good soldier was made a Political, a fact that may palliate the cool statement made by a great Indian ex-official a year ago, before the Royal Geographical Society, that the success of every frontier military expedition which he had known was due to the ability of the Political Officer. Political Officers have often brought disaster upon the expeditions which they accompanied, as the Duke of Wellington told Lord Ellenborough after the Macnaghten and Burnes fiasco in 1841 at Kabul. The opinion of Sir Joseph Thackwell, who commanded the cavalry at the Battle of Goojerat, on this subject is thus expressed: "A solemn protest must be made against the system of hampering the Commander-in-Chief with Political Agents. Lord Gough was entangled with these political shackles. Major Mackeson, the Governor-General's Agent, controlled the movements of the Chief. Sir Charles Napier would not undertake the office of Commander-in-Chief save on the condition that he should be perfectly exempt from all control in the field. The mischief of which the Political Agents have been productive is prodigious."

Now let me relate an incident of these wars which shows that we English are in no way behind in testifying our admiration of an enemy's valour. In the fort at Hyderabad, Sind, hard by the tombs of two British officers slain at Miani and Dubba, stands a monument, the inscription on which records the death, "while bravely fighting the gun placed over his tomb," of the Ameer's soldier buried there. Whether it is the tomb of Hosh Mohammed Sidi, to whose bravery Charles Napier himself is a witness, I have not been able to decide. The body was brought in by Napier's English troops and honoured by burial side by side with Napier's English officers. In 1898 an old man, who had fought at Miani, took me to see the site of Outram's Residency, near Hyderabad in Sind, close to the left bank of the Indus. The story of Outram's escape therefrom in 1843 to the Indus Flotilla boats is told in Outram's "Life" and Sir William Napier's "History of Sir Charles Napier's Administration in Sind." The traces now of the old Residency are mere unevennesses of the ground.

As Kaye, in his "History of the Afghan War," says nothing about Upper Sind and the hill regions below Quetta and Pishin, little is known of the fighting in that quarter from 1839 to 1842 and later. Yet the famous John Jacob took a most prominent part in it. That 5th Bombay Light Infantry which sat so tight at Kāhun was then nicknamed the "Kāli Paltan," because it was recruited from small dark Bombay men. At that time the Bengal army recruited mainly in Oudh and the North-West, the Bombay in its own Presidency, and both in Rajputana. The Madras army recruited in Southern India. The old Coast army of the eighteenth century was recruited from all parts, and from all kinds and conditions. You know, naturally, that the Mutiny wiped out many of those old regiments which had in their day done gallant service. A solid stiffening with British troops was, as a rule, essential to the best exercise of their prowess. On the other hand, at Lake's siege of Bhartpur, it is a positive fact that Bengal Sepoys planted themselves on breaches which British regiments had failed to reach.*

The Madras and Bombay armies rarely, if ever, made any difficulty about serving overseas. The Bengal gave much more trouble in this respect, though it is recorded that they served

* The Bhartpuris are Jāts, and many think the Jāts are gipsies. Knowing as we do the gipsy's love, not for a walled city, but for the life of the open country, this gipsy theory about the Bhartpuris must be regarded as illusory.

in Java and Isle de France. But only *batta* reconciled them to Sind and Trans-Sutlej service, and to Burma in 1852 they refused to go. This spirit is now dead or dormant in the Indian Army and in India. As we know, almost all classes of Indians now visit Europe freely, and the present war proves that the Indian soldier will go anywhere and do anything. When duty spares them from the theatre of war in France, they may occasionally be seen dining at the Carlton.

I am afraid I have said scarce a word about the long First Afghan War, so full of incident, romance, and deeds of derring-do. The defence of Herat by Eldred Pottinger took place in 1836, and he it was who, with John Colpoys Haughton, had such a marvellous escape from Charikar in November 1841. "We welcomed them as men risen from the dead," wrote Lady Sale. The storming of Ghazni, in which Lieut. Henry Marion Durand played a notable part, the defence of Jalalabad, the vicissitudes endured by the Kabul captives and the Ghazni prisoners, the fates of Burnes and Macnaghten, the terrible scene of which Lady Butler's "Remnant of an Army" is a speaking memento,* and finally the revenge of Nott and Pollock; these are some of the memories of that war. The well-known Chaplain-General Gleig said of the 13th Somerset Light Infantry, who served from start to finish of the war (that is, for four years): "At the end they were as good as any Afghan on a hillside."†

Those words often come back to me when I read the accounts of the frontier fighting in the Tirah and Momand countries in 1897-98. Hillmen or Alpine troops are not made in a day. If you will walk across the Alps from Briançon to Fenestrelle, you will see how the French and Italians train their Alpine troops. Some of the French Alpine troops have been fighting on skis in the Vosges, and Germans also. We have none so trained, the result being that when our troops are ordered on such service they require, like our early Territorials, six months' training before they know their work.

When we go back to the momentous period of the Sikh, Burmese and Persian Wars, and the Mutiny, between 1845 and 1859, never-to-be-forgotten names rise up before our memories, to wit, Herbert Edwardes, Harry Lumsden, Henry Norman, William Hodson, Hugh Gough, Charles Napier, Sydney Cotton, John Nicholson, James Outram, Henry Havelock, Harry Smith, Colin Campbell, Neville Chamberlain, George Broadfoot, Henry and John Lawrence, and last, but not least, the revered veteran who passed away last December in the midst of Sir John French's army, Field-Marshal Lord Roberts. Gujerat, Chillianwala, Sobraon, must be passed over in silence. That fine old Indian soldier Sir Henry Green who with Jacob crushed the Baluch freebooters and charging with 300 Sind Horse routed 1,500 Afghan cavalry at Gujerat, in 1858 marched alone with the lawless Kelat troops right through the Bugti-Marri country, a dangerous experiment, not a tribesman, however, daring to touch him, and brought back the one gun which "Kāhun Brown" had been unable to carry away with him when he marched out with the honours of war. Sir Henry Green, twenty years ago, sent me a copy of a most interesting report which he had sent to Lord Wolseley on his experiences in the Sikh wars and frontier warfare. Green and Wolseley served together in the trenches before Sebastopol, and were lifelong friends. Green and Jacob served together for fifteen years or more on the Upper Sind frontier, and Green just got back from that Bugti-Marri march in time to see his old friend breathe his last. There are two men at whose grave or monument the natives of India still make obeisance. They are John Nicholson and John Jacob. Outram and Jacob carried our arms into Persia in 1856. We little foresaw then German influence at Baghdad. In 1890 I met the first German sent to spy out Baghdad, M. Richarz.* He was appointed

* I am informed by the descendant of an officer killed in the massacre of Elphinstone's army that Dr. Brydon, the one man who escaped, owed his life to carrying a copy of *Blackwood's Magazine* in his helmet. It broke the blow of an Afghan tulwār. Lady Butler depicts Brydon bareheaded.

† It is Harry Lumsden, of the Guides, and his brother Sir Peter, who speak so highly of Sir Colin Campbell as a Frontier leader. That fine soldier who declined the Viceroyalty of India, Field-Marshal Sir Henry Norman, was in those days—*i.e.*, about 1850—on Sir Colin's staff. These are the words of Lumsden's biographer: "In all retirements he stuck doggedly to the rearguard until he saw the last of his column safely out of danger." In the Tirah Campaign Sir Richard Westmacott and Colonel John Haughton acted up to that maxim, and won honour accordingly. If Colonel John Haughton's gallant death had taken place more directly under the eyes of the Nation and the War Office, he would, I venture to believe, have been awarded the Victoria Cross after death.

* We met at Karachi on the Messageries-Maritimes boat, and travelled home together to Marseilles. He told me he had been there two years, engaged in archæological work, having a steam-launch of his own. He was an excellent pianist, and fortunately the M.-M. piano was a good instrument. His conversation left the impression on my mind that the British Resident at Baghdad was a "slacker," and the Russian Agent an active intriguer among the Arabs. The *Times* of March 10th, 1915, has an interesting leader in this connection on "A Picture of German World Politics," and No. 29 of the *Times* "History of the War" still further enlightens us. Lastly, an India Office *communiqué*, of March 19th, 1915, sheds light on the intrigues of German consuls and traders in Persia, and on Persian intrigues in which the German Legation at Teheran are clearly implicated.

German Consul-General there in or about 1891. He did not foresee that he was paving the way for a British protectorate over the Shatt-ul-Arab district, which General Sir A. A. Barrett's force has now occupied, and to which the Viceroy of India has promised, in the near future, a more "benign rule."

The "Napier" antagonism burnt so strong in Jacob's breast that it extended to the two Napier Baluch Battalions, now the 127th and 129th. If Jacob had had his own way, he would have had them disbanded in 1856. They rewarded the Commander-in-Chief in Bombay for his indignant refusal to do any such thing that very same year in Persia, and afterwards throughout the Mutiny, by rendering to the Government the most loyal service. Lord Napier of Magdala specially recognised the services of the Baluch Battalion at Delhi, and in Oudh and Rohilkhand, and again had them under his command in the Abyssinian expedition of 1868; and Captain Griffith, of the 61st Foot, in his "Mutiny Diary," sums them up in these words: "The Belooch Battalion, a savage-looking lot of men, who, however, did good service and fought well." They are now fighting very well in France. The laurels which they have already won are a V.C., the first ever won by an Indian soldier, two Indian Orders of Merit, and four Distinguished Conduct Medals. Of these seven soldiers, five have been killed, and one, Private Khudadad, V.C., very seriously wounded.

Among my private papers is a remarkable story connected with the first Sikh war. On the night of December 22nd, 1845, the wife of a well-known London clergyman (his name is in the Clergy Lists of that period) dreamed that she saw the postman hand to her a black-edged letter containing her son's commission. Her son had very recently joined a regiment of the Indian Army. On the morning of December 23rd she told her husband of her dream, and later in the day other friends. In due course the father and mother heard that their son had been killed on December 22nd, 1845, in the very first action of the first Sikh war, that of Firozshah. It seems clear, from an examination of dates and having due regard to the comparative slowness of communication between Lahore and London in 1845, that not even a rumour of the coming Sikh war could have reached the ears of the parents by the night of December 22nd. For the rest, I leave the case in the hands of the Psychical Research Society.

In the sixties of the last century the Presidential armies of India began more to conform themselves to that composition and classification which is now in vogue. Details on such a point as this must really be left to official publications; but I can assure you that a study of the brief historical headings which now appear in the Indian Army lists will well reward the reader. We have come to the era of the Gurkha, Pathan, Sikh, and Punjabi, an era which for the three races last named may be said to date from 1850. The Gurkha entered our service from 1815 onwards—in short, immediately after the conclusion of the Nepal War, in which the gallant Sir Rollo Gillespie was killed, and Sir David Ochterlony, a close friend seemingly of the Begum Sumroo, won his laurels. It is evident from Jacob's aversion to them that Pathans had found their way into the East India Company's service some years before his death. Jacob detested them, and many others have denounced them. They claim an Israelitish origin. Moses pronounced the Israelites "stiff-necked"; the Pathan does full justice to his reputed forbears, and makes none the worse soldier for it. Could Jacob—not the Patriarch, but the famous Frontier officer—have foreseen that Afridi Maliks would in 1915 give garden parties in the Islamiya Garden at Peshawur, and invite thereto the Chief Commissioner of the North-West Frontier Province and the *élite* of the local society?

For those who desire statistics about the Indian Army there is an excellent article by Mr. Vivian in the January number of the *Asiatic Review*, and another in the February number of the *National Review*. All space permits me to say is that when war broke out the British Empire could look to a regular Indian army 160,000 strong (British troops excluded), consisting of thirty-nine regiments of cavalry, about 140 battalions of infantry, thirteen mountain batteries, and three corps of sappers and miners. To these are to be added 39,000 volunteers, 22,000 Imperial Service Troops, and 35,000 Indian Army reserve. The duty of the Volunteers, composed of Europeans, Eurasians, and Parsis, is to preserve peace in India. The rest serve in India or abroad. Pathan, Punjabi, Gurkha, Sikh, Mazbi, Dogra, Rajput, Maratha, Jāt, Garhwāli, Hazara, Baluch, Mhair, Brahman and Mussulman of Hindustan, and inhabitants of Kashmir, the Carnatic and the Deccan—all these races are represented in the Expeditionary Force under

General Sir James Willcocks now fighting in France.

The Russian attack on the Afghans at Penjdeh, on March 30th, 1885, is said to have given rise to the idea which has matured in the fine force known as the "Imperial Service Troops"; and it was also about that time that it was decided to confer honorary rank in the British Army upon the most distinguished of His Majesty's Indian subjects. The Imperial Cadet Corps, formed under H.H. Sir Pratap Singh, is an Officers' training corps for the princes and nobility of India.* It fell to the lot of the late Field-Marshal Sir George White, as Commander-in-Chief in India, to amalgamate the three Presidential armies in one.

Among the native attachés who accompanied the Afghan Boundary Commission of 1884–86 were some of the picked men of the Indian Army, viz., Hon. Colonel Sir Mahommed Aslam Khan, Commandant of the Khyber Rifles and an Hon. A.D.C. to the King, who died not long ago, and Risaldar-Major (afterwards Hon. Captain) Baha-uddin Khan, of the Central Indian Horse, and others. We count now among the hon. major-generals and field officers of the British army and hon. aides-de-camp to the King several reigning princes of the Indian Empire, whose loyalty and ability His Majesty has desired to recognise, and it has for some time been customary to confer the honorary rank of captain or lieutenant on senior officers of the Indian Army when they retire on their pensions.

The *Times* includes in its excellent "History of the War" two ably written Parts (Nos. 22 and 29 of Vols. II. and III.) devoted to the Indian Army as it is seen in France, Egypt and the Persian Gulf to-day.† Two months ago it was stated that the Indian Expeditionary Force in France, not a large one, had had 10,000 casualties, including 228 British officers. One battalion, I know, had by Christmas lost 75 per cent. of its original effective. In our last important war, in South Africa, the only Indians we sent there were hospital bearers and orderlies and ambulance tonga drivers. They did admirable work. Since then the formation of the Indian branch of the St. John Ambulance Association has been carried out.* I laid my scheme for this, in 1900, before the late Viscount Knutsford, and, at his request, undertook the task of organising and establishing the branch. This, thanks to help from many good friends, I was enabled to do, as Lord Knutsford publicly acknowledged in a speech in the House of Lords on July 21st, 1910.† The Indian Army has greatly profited by this during the present war, in which we have loosed all that can be spared of the strength of our magnificent Indian Army and Indian Empire against our foe. In self-defence we could do no other. On December 8th, Sir John French telegraphed to Sir James Willcocks: "I owe the Indian troops a deep debt of gratitude for the splendid services they have rendered," and after the fighting from March 8th or 9th to the 14th, near Neuve Chapelle, both Sir John French, in his telegram to the Viceroy of India, and Lord Kitchener, in his speech in the House of Lords, testified to the fine behaviour of the "I.E.F." Humbler but not less telling evidence appeared in the Press. The Indian Army will now take its place as an Imperial Force, a position for which it has for more than a century and a half been vigorously qualifying. When our naval and military leaders first met the French in India, a blow was struck for the Empire. When Indian troops landed in Egypt (1801 and 1882), and in Malta in 1878, they foreshadowed the part they play to-day. When they mingled in 1900 among the army of all nations at Peking, they were serving a phase of their apprenticeship. The Germans, as insolent as they are ignorant, called them "coolies." An Indian chieftain and soldier of the purest

* In the discussion which followed this paper attention was drawn to the necessity for establishing in India a Military and a Staff College, similar to those at Sandhurst, for the education and training of Indian officers, if they are to become "leaders of men" equal to our British officers. To some such result this war seems likely to lead. Our public schools have been a tower of strength to the Army at this juncture, and the Prime Minister himself paid in Parliament a just tribute to the Universities of Cambridge and Oxford as military training schools. India has her Aitchison, Mayo and Aligarh Colleges, which may well begin this work which the future military colleges of India will complete. It will doubtless be open to the great Princes or groups of Princes of India—Rajput, Sikh, Mahratta, Mussulman—to found their own military colleges, the instructors being, at the outset, British.

† Our operations in the Persian Gulf have led not only to fighting on the Shatt-ul-Arab, but also to war between Arab adherents of the British and Turkish Governments (in these Captain Shakespear lost his life), and to a Turkish invasion of neutral Persian territory near Ahwaz, where the Turks were ultimately, it seems, repulsed. They aimed at the oil-pipe line, and it seems to be thought in some quarters that they cut it.

* To give an idea of medical provision a century ago, it is recorded by "Carnaticus" that "there was great want of medicines, scarcely a bit of dressing-plaster, and no amputating instruments, except those belonging to individual surgeons. Out of every three amputations two died in hospital."

† Sir Steuart Bayley (whom I had consulted about this project) very kindly invited me to lecture on this ambulance scheme in or about November, 1900, before the Royal Society of Arts. I have always regretted that I was unable to accept this invitation.

Rajput blood never forgot that word "coolie," and he and his brother Rajputs are now wiping it out on the battlefield of Northern France. When they landed at Marseilles, Pathan and Gurkha pipers played the "Marseillaise" through the streets of the home of that famous patriotic song. Sir James Willcocks will not impossibly march his Indian force to the strains of the same pipes down the "Unter-den-Linden" and past the palace of William the Second before they return to India. The German Emperor, throwing down his gage of war, and trusting to sow discord, wove the web of "Peace" among contending factions, and drew the bond of union closer between each unit of our Empire. He relied on his compact with the Turk to alienate from Great Britain her Mohammedan millions. He has but strengthened the ties that attach them to us. The commanding officer of a Mussulman regiment wrote to me from India, "Our men are dying to have at the man who seduced Turkey." Our great departed soldier, Lord Roberts, sees his cherished scheme of a National Army practically realised. As the Dean of Manchester said, the war has made class respect class, and we know what its effect has been upon "Party." When we glance backward over the history of our Empire during the past sixty years; when we reflect that some heedless indiscretion or arbitrary impulse might have raised up in Canada, New Zealand, or Australia a second Washington or Franklin; when we recall the Mutiny, the war in South Africa, and the slenderness of the tie that forty years ago bound the Dominion of Canada to the Crown, we can but rejoice and be thankful that a glorious union now animates the peoples of our world-wide Empire, and that our King commands the services of a Navy and Army which in themselves are the mightiest witnesses to our unity. And let me suggest one other reflection. If in the eighteenth century we won India from France and in the nineteenth century safeguarded it from Russia, in this twentieth century we hail both as our trusty and valued allies in the stubborn task of teaching the Teuton and the Turk their true sphere.

The movement of a division of the Indian Army to Mesopotamia, a country rich alike in soil and in Biblical tradition, is an event of high significance, whether it be regarded as a step towards that hegemony of the Mohammedan world to which Great Britain has some authority for aspiring, or whether it simply portends an annexation of territory. We must remember that the Turks looted Kerbela of two millions sterling. The British Empire has guaranteed the protection of the Holy Shrines of Islam, and that guarantee embraces Kerbela as well as Mecca and Medina, and the Shi'ah as well as the Sunni. Constantinople plunders the Shi'ah without scruple. The problem of the fate of the remnant of European Turkey and of the Dardanelles is not for discussion here. The best future for Mesopotamia is that it should be joined to our Empire, and colonised by some of the vast surplus Mussulman population of India. Sir William Willcocks, an Englishman, has projected a scheme for restoring its system of irrigation; let the English race administer it. Indian emigration is one of the crying needs of the day. Mesopotamia and Southern Persia will surely commend themselves to the notice of the emigration office of the Indian Government. We cannot, I think, do better than reward the gallant ranks of the Indian Army—whether commanded by Sir William Willcocks's brother in France, or by other generals elsewhere—with jaghirs and grants of land in the fabled home of the first Parents of Mankind.

DISCUSSION.

The Chairman (The Right Hon. Viscount Bryce, O.M., D.C.L., LL.D., F.R.S.) said the audience had listened to an exceedingly interesting and suggestive paper. Colonel Yate certainly had had a worthy theme for his large and recondite knowledge, because the story of the Indian troops was inextricably associated with the whole romantic and varied history of British rule in India. The paper suggested a great many subjects upon which discussion might turn, and opened up many vistas, both political and military, which it was not possible at the present time to follow. Colonel Yate had pointed out what he (Lord Bryce) thought was one of the most interesting things in Indian history and in British history, viz., the gift which British people seemed to have possessed, perhaps beyond those of any other European race, of getting into touch with the natives of another country and of another speech—even when they did not fully understand that speech—and of being able to secure their loyalty and attachment, the gift of entering into their hearts and feeling with them and for them, and showing themselves apt leaders of brave men. Colonel Yate had also pointed out what a magnificent training-ground the experience of India was for many great soldiers. Time had not permitted him to speak of the early career of Sir Arthur Wellesley; but everybody knew that the experience which Sir Arthur had in India, and

the opportunity which India gave him of displaying his great gifts, made him the man most fit to be chosen at the darkest hour of England's fortunes—when the power of Bonaparte seemed to be overspreading the whole Continent—to take command of our troops in the Peninsula, and to begin that career of conquest which ended at Waterloo. During all the years from Clive's time downwards there was arising in the Indian Army that spirit of loyalty and of devotion to its leaders, as there was arising amongst us and amongst our soldiers that appreciation of the noble qualities of the Indian troops, which had now found a most remarkable illustration and display in the events of the last eight months. Those events had been by far the most remarkable events in the whole long and brilliant history of the Indian Army. It was impossible to conceive a more striking instance of the loyalty and attachment of the people and princes and troops of India to the British Empire, than was displayed when that spontaneous offer, which touched us all, came in the month of August last. Since then, what deeds of brilliant valour! The Indian troops had shown themselves worthy compeers of our own troops and the troops of our Allies, not only in courage and devotion, but in endurance of hardships, and in unfailing loyalty. It was one of the redeeming incidents of a time so full of sorrow for all, that that spirit of attachment should have been shown by the people and princes and troops of India to the British Empire. This was a new tie, and perhaps the deepest and the most binding of all ties, that would hereafter unite Great Britain to India; because it showed that the efforts Great Britain had made in discharging worthily the duties which Providence had laid upon it, and the spirit in which Britain had tried to discharge those duties, had been appreciated in India. On the other hand, it showed that the people of India recognised that the future had in store for them, as for us, a closer connection than ever before, based upon the endurance of common suffering and upon the devotion to a common cause. It might reasonably be hoped that this country's relations to India would rest upon a surer foundation of mutual affection and respect hereafter than it was possible it ever could before, and that was one of the compensations for all the struggles which we were now called upon to endure. There was every reason to believe, and to hope, that there would henceforth be a feeling of common interest and pride in the glory of the Empire and a common devotion to its welfare.

Sir Steuart Colvin Bayley, G.C.S.I., said there were one or two points on which he could have wished Colonel Yate had dwelt a little longer. As it was, however, he had given a delightful paper, beginning with war and ending with war, in the midst of it being a great deal of what the Scotsman said of a sheep's head, "Good confused feeding." One point which he wished the author had made a little more of was the early beginning of the Indian Army in the different Presidencies. He himself had looked up the subject when studying the history of Lord Clive a few years ago, and he got to be interested in it very much indeed. As the author remarked, the Sepoys with whom Clive had to fight the French were a very nondescript lot; they were very little better than the soldiers of the native Courts. They were armed better, because we armed them; and occasionally supplied a non-commissioned officer to drill them. Later, English officers also commanded them in the field. They were men who had taken up a military life, and they came in the following way: A jemedar, or any partisan leader who had collected a hundred men or so, would bring them and enlist them as a separate company, and they remained separate companies. On one occasion in Madras no less than 600 came over from the defeated enemy with their native officer. They appeared to have thought that Clive was in the ascendant, and that their own commander was decadent, and, therefore, they joined Clive in a body. In fact, they resembled the *condottieri* of the Italian wars and the followers of Dugald Dalgetty. That was the way things were managed as long as Clive was fighting the French in Madras. When he went to Bengal, in 1757, he changed things a good deal. He landed in January, and proceeded to form a regiment. Instead of having individual companies, he formed what was called the Red Regiment. He drilled them with European non-commissioned officers, clothed them in the same uniform as his own soldiers, gave them British arms, and British officers to command them in the field. The first battalion numbered a thousand, and included Pathans and Rohillas, Rajputs and Jats, but mainly up-country Mussulmans. Clive raised another battalion of the same size in August of that year, and a third battalion before the year was over. He left Bengal and came back six years afterwards as Governor of Bengal. By this time there were twenty of these battalions. He then took a larger and very much more important step. The British officers up to that time in the Bengal army had been in one general list, and were temporarily attached to different regiments for particular purposes in the field. Clive did away with the general list, and broke it up into regimental lists; that was to say, an officer was attached to a native regiment during all his service. Then he brigaded those native infantry regiments with a due proportion of other arms of the service, each brigade being under a general officer. That was the system which Clive founded in Bengal, and which

lasted for about a hundred years until the time of the Mutiny. That system produced a class of officer of which Colonel Newcome, in Thackeray's book, was a typical example. He (the speaker) did not object to Stringer Lawrence being called the grandfather of the three Presidential armies; but he did think that Clive was the father of the Bengal Presidential army.

Colonel Sir Thomas H. Holdich, K.C.M.G., K.C.I.E., C.B., D.Sc., called attention to one point on which the author had not insisted, and which demanded a little more attention than it received in the present day, when the public at home desired to know as much as possible about the Indian Army. He referred to the extraordinary admixture of nationalities of which that army was composed. If Roumania, Italy, and Greece were to join with Belgium, France, and England in the present great war, there would not be amongst the Allies quite as large an admixture of totally distinct nationalities as existed among the Indian Army at present serving with them. They were not only distinct nationally, but they were distinct in their idiosyncrasies and in their social customs. There was a tendency to pay attention to the picturesque side of an army, and to admire, perhaps in a greater degree than was fair to the rest, certain regiments, or certain groups of regiments, which more or less filled the public eye. In the British Army he thought that was the case with the Highlanders. They really occupied a good deal of public attention when there was no war going on. Why that should be so he could not quite understand. It was not because the men were Scotsmen, because very often they were not; but there seemed to be something about their dress which attracted everybody's attention to them, and made them popular heroes wherever they went. It was the same more or less in the Native Army. There was a notion that the Indian Native Army consisted of Sikhs and Gurkhas. Sikhs and Gurkhas made very fine soldiers, and no doubt were to a large extent the backbone of the fighting strength of the Indian Army; but they did not compose the whole army. It was therefore with very great pleasure that he had heard what the author said about his own particular section of that army, the Baluchis, and that he had heard directly and privately from the seat of war of the excellent performances and fine fighting qualities of the Mahrattas and Rajputs. It was a satisfaction to think that those perhaps rather unconsidered units in the great Indian Army were getting a little bit of their own back again. They had been good fighting men in their time, and their traditions were evidently still with them. He entirely agreed with Lord Bryce in thinking that after the war all India, both military and civil, would be knit together in a new bond of loyalty to the British Government, which would last as least as long as those hardy warriors who had served so well in the trenches. These men, when they returned to their native villages and sat in the market place, or under their own peepul trees, would tell their children and their children's children of the great deeds done while they were fighting in Flanders shoulder to shoulder with the Sahibs.

Colonel C. E. Yate, M.P., C.S.I., C.M.G., said reference had been made in the paper to the Imperial Service troops and the Imperial Cadet Corps, and he would like to explain what they really were. The Imperial Service troops might be termed the outward and visible sign of the loyal desire of the great ruling chiefs of India to take their proper share in all actions for the defence of the Empire. Those troops were raised by the ruling chiefs, and were mostly composed of the men of the Native States to which their officers also belonged. They differed from regiments in the Indian Army in having no British officers. All present knew that each regiment of the Indian Army had, as a rule, an establishment of fourteen or fifteen British officers as well as seventeen or eighteen native officers. The Imperial Service troops practically had only the Native officers. Nothing had been more completely proved during the present war than the necessity of a large establishment of trained British officers with all Indian regiments. Without the leadership of scientifically-trained British officers the Indian was helpless in France and Belgium. He did not wish to see British officers posted to Imperial Service regiments, but if the Imperial Service troops were to form a permanent part of the Imperial army they would have to be put in the same position of equality, so far as the training of their Indian officers was concerned, as British and Indian regiments. With regard to the Imperial Cadet Corps, he hoped to see it very much more than simply a training corps for the princes and nobility of India as described by the author. He hoped to see, in the future, every State in India contribute its due and proper proportion of Imperial Service troops on an equal basis with regard to its revenues and its treaty obligations with the British Government. He looked forward to seeing Indian cadets from the Imperial Cadet Corps drilled and trained in an Indian Sandhurst, as were English cadets in England; after that they might be gazetted out as second lieutenants to the Imperial Service regiments and be eligible to go up with British officers to the same boards of examination and exactly under the same regulations; to be examined at the same time for promotion; to be admitted on equal terms to the Staff College at Quetta; and

to be sent through the varied courses of instruction in India on perfectly equal terms with British officers. We should welcome them with open arms as loyal comrades in arms; but if the Imperial Service troops were to take their proper place in the Imperial defence, it was necessary that their Indian officers should be as well trained as British officers. He hoped the Indian Government would take up the question in all seriousness.

THE RIGHT HON. SIR HENRY MORTIMER DURAND, G.C.M.G., K.C.S.I., K.C.I.E., in proposing a vote of thanks to the author, said he was in France the other day and went to see the Indian wounded in one or two hospitals. The cheeriest and most amusing fellows he saw were two wild frontiermen, Mahsud Wazirs. They were in the highest spirits and extremely pleased with themselves. He said to one of them, "I suppose you know that your tribe is fighting against us at the present moment." The man roared with laughter, and said, "No, sahib, are they? The blackguards!" And then, "Sahib, are they putting up a good fight?" As to the Imperial Service troops, he himself was responsible to some extent for the fact that they had not any British officers. It was thirty years ago, after the apparent imminence of war with Russia, and the great display of loyalty which was shown by the Indian chiefs of that time, that the idea of forming corps of Imperial Service troops was brought forward. He was with the Government of India at the time, and the idea was not only to raise a supplemental body of good troops out of the rather loose, undisciplined levies of the chiefs, but to afford an outlet for the martial spirit of the Native States. Therefore it was specially laid down that there should be no officers except those from the Native States themselves. But nobody then anticipated that those Imperial Service troops would be called upon to fight the Germans in France. He was sure the Society and all present were very grateful to Lord Bryce for being so good as to spare time from his very numerous engagements to preside at the meeting, and for making the speech to which they had listened with so much interest.

The resolution was seconded by SIR STEYNING W. EDGERLEY, K.C.V.O., C.I.E., and carried

THE FOREIGN POPULATION OF MILAN AND LOMBARDY.

From some statistics lately published in a Milanese journal it appears that the foreign population in Italy has increased about one-third since 1881. Amongst the various regions of Italy, Lombardy contains the largest alien population, whilst about 60 per cent. inhabit Milan.

The following show the relative number of foreign inhabitants from 1881 to the present time:—

Year.	Foreign Population in		
	Italy.	Lombardy.	Milan.
1881	About 60,000	12,254	5,641
1901	„ 61,600	11,947	7,761
1914	„ 80,000	17,258	10,110

The foreign population of Milan has increased at the rate of about 2 per cent. every year between 1881 and 1901, and 3 per cent. during the last thirteen years.

Respecting nationality, it is estimated that 90 per cent. are Europeans, 79 per cent. being natives of the following four countries:—

Switzerland	2,598
Austria-Hungary	2,142
Germany	2,129
France	1,033
Total	7,902

The number of English residents in Milan does not exceed 426.

MOVEMENT OF SHIPPING AT MARSEILLES, 1914.

The Port Authority of Marseilles has published the following statistics of the movement of shipping during the past year. These figures show clearly a considerable falling off in the traffic of that port which has taken place since the outbreak of the war. The number of ships which entered during the year ending December 31st, 1914, was 7,234, with an aggregate tonnage of 8,992,977, with 5,203,876 tons of merchandise and 249,626 passengers. The sailings were: 7,201 ships, of an aggregate of 8,961,930 tons, 2,999,579 tons of merchandise and 216,076 passengers. The total movement (arrivals and sailings) for the twelve months was, therefore, 14,435 ships, 17,954,907 aggregate tonnage, 8,202,955 tons of merchandise and 465,702 passengers. This shows a decrease of 2,843 ships, with an aggregate tonnage of 3,135,913, 1,644,600 tons of merchandise and 11,468 fewer passengers, as compared with the traffic during 1913.

It may be observed, however, that the returns for the first six months of 1914 show an increase of 118 ships, with an aggregate tonnage of 551,000 and 48,500 tons of cargo; so that, taking this into account, the total decrease due to the war may be estimated at 2,961 ships of 3,686,913 aggregate tonnage and 1,693,100 tons of cargo. These figures do not include the number and tonnage of the vessels chartered by the Allies for the transport of troops and war material, the landing of which was the cause of great activity at the port, particularly during the months of August and September last year.

MANUFACTURE OF CONCENTRATED APPLE CIDER IN AMERICA.

The specialists of the Fruit and Vegetable Utilisation Laboratory of the United States Department of Agriculture have completed arrangements for a commercial test of the recently discovered method of concentrating apple cider by freezing and centrifugal methods. As a result a cider mill in the Hood River Valley, Oregon, has undertaken to manufacture and test on the retail market 1,000 gallons of concentrated cider, which will represent 5,000 gallons of ordinary apple cider with only the water removed. The new method, it is believed, makes possible the concentrating of cider in such a way that it will keep better than raw cider, and also be so reduced in bulk that it can be shipped profitably long distances from the apple-growing regions. The old attempts to concentrate cider by boiling have been failures, because the heat destroys the delicate flavour of cider. Under the new method nothing is taken from the cider but the water, and the resultant product is a thick liquid which contains all the apple-juice products, and which can be restored to excellent sweet cider by the simple addition of four parts of water. The shippers and consumers, therefore, avoid paying freight on the water in ordinary cider. In addition, the product, when properly barrelled, because of its higher amount of sugar, keeps better than raw cider, which quickly turns to vinegar. The process, as described by the specialists of the Department of Agriculture, consists of freezing ordinary cider solid. The cider ice is then crushed and put into centrifugal machines such as are used in making cane sugar. When the cider ice is whirled rapidly the concentrated juice is thrown off and collected. The water remains in the machine as ice. To make the concentrated syrup, the cider mill must add to its equipment an ice-making machine and centrifugal machinery; so that the process is not practicable on a small scale. The specialists are hopeful, however, that the commercial tests to be inaugurated will show that it will be possible for apple-growers to concentrate their excess cider and ship it profitably to the far South or to other non-producing regions. The specialists also believe that it will enable apple-producers to prolong the market for cider.

RECENT INCA AND PRE-INCA DISCOVERIES.

The researches and travels about Cuzco, which are being pursued with considerable energy and interest by American antiquarians, and which have brought to light not only Inca but also pre-Inca remains, encourage Professor E. A. Ross to anticipate that at no distant period Cuzco will become a great goal of pilgrimage like Rome, Jerusalem and Cairo, and make the fortune of a Cook who could organise a good tourist service.

Since the discovery by Professor H. Bingham, of Yale, of the wonderful stone city of Machepicchu, 2,000 ft. above the River Umbamba, at a point about two days' journey from Cuzco, much discussion has arisen among the expert antiquarians of the latter city as to the aboriginal remains of this region; for it has been revealed that of these pre-Inca times the Incas themselves knew nothing. Dr. Giesecke, the American rector of the University of Cuzco, has travelled altogether more than 10,000 miles in quest of relics of the past, and, interesting as the finds are, the Doctor declares he and his companions have not done more than scratch the surface. Portions of fourteen palaces of Inca rulers line the streets of Cuzco, and much of the walls of the Temple of the Sun has been incorporated into the Church of San Domingo. These walls are of finely-cut blocks laid in courses without cement. It has often been said that the joints in the walls will not admit the point of a knife blade or needle being inserted between the great blocks, and the microscope shows that the stones were wrought with tools of champi, an alloy of copper and tin.

The vast fortress above Cuzco with its stupendous stonework belongs to a period long before the sun worshippers existed. They are supposed to be in all probability monuments of the same civilisation as those at Tuahuanacu, a few miles south of Lake Titicaca, at an elevation of 12,000 ft. Here lie the ruins of a city of a million inhabitants, the existence of which is accounted for by the idea that it dates from a period when the Andean Plateau was some thousands of feet lower than now, and thus enjoyed a milder climate. Three hours' ride from Cuzco is Chinchero, an Indian town, whose plaza occupies the site of a great Inca palace, the niched side-wall of which is still standing. Below slope royal gardens surmounted by numerous seats, stairways, and passages, cut with beautiful precision in the living rock. Here, no doubt, were wont to sit the Incas while they took their ease and feasted their eyes over the abundant and picturesque panorama. The remote valley is a peephole into the old simple life of mankind before the advent of trade and requirements and letters—the life of Egypt, Babylonia, of the Hittites and Etruscans, before ever there was Jew or Greek or Roman.

ENGINEERING NOTES.

The First Steel Manufacture in Australia.—Amid the din of war it is satisfactory to know that Australia was helping last month to increase the world's supply of steel. Mr. Paull, an expert from Scotland, a few years ago was employed by the New South Wales Government to report on the matter, the result of which has been the completion of the works in Newcastle, New South Wales, run by the Broken Hill Steel Proprietary Company's works. It is hoped that, notwithstanding the high price of labour, the local importation of iron ore will enable the work to be carried on profitably. It is understood that the South

Australian Government has already accepted a tender from the Company for the supply of 2,000 tons of 60-lb. steel rails, and 140 tons of fish-plates. The rails will be manufactured on the basic open-hearth method, and the Sandberg process applied. In connection with the utilisation of some of the large iron-ore deposits in the same State, it is interesting to note that a shipment of 2,800 tons of ironstone was recently dispatched to the Company's works at Newcastle. The ironstone was obtained from Iron-Knob, some forty-one miles from Port Augusta, where is situated the largest deposit in that State. This is contained in two great ore-bodies known as the Iron-Knob and Iron-Monarch, the latter being the larger of the two. The ore from the Iron-Knob has, during the last twelve years, been used by the Proprietary Company for fluxing purposes at the smelting works at Port Pirie, and its average content of metallic iron has been found to be over 68·5 per cent. The extent of the deposits has not yet been actually determined, but on the assumption that the average depth of ore is no more than 100 feet, it has been calculated that over 21,000,000 tons of ore are available.

The Failure of the Panama Canal Crane.—The Panama Canal Commission decided some time ago to purchase two large floating cranes. These cranes were intended to handle such heavy loads as the largest dock-gate leaves. They would have to meet the needs of the Navy Department and be capable of lifting any weights which have to be moved in connection with the repair of warships, or the heaviest guns to be mounted on the Canal fortifications. The possibility of the cranes being required for the wrecking work on commercial vessels led the Commission to decide on two cranes of 250 tons capacity each. On January 13th, 1913, four tenders had been received. These were the Deutsche Maschinen Fabrik A.G., of Duisburg, Germany, £171,000; the Werf Gusto, Holland, £192,000; Cowans, Sheldon Company, England, £230,000; and the Welman-Seaver-Morgan Company, U.S.A., £300,000. The contract was finally awarded to the German firm. The crane consists of a tower on which is mounted a revolving jib 140 feet long, weighing 165 tons. The cranes, complete as to hull and superstructure, were towed out to Colon from Emden, the jibs being shipped separately. The first crane left Emden in April last, and was seventy-four days on the voyage owing to bad weather. Tested on December 1st with a 120-ton load, which was not even out to the specified distance, the jib collapsed. Fortunately only one man was injured, but the damage is estimated at £25,000 and will take six months to repair. In commenting on the accident, a writer in *Engineering* expresses the opinion that some lateral stress, caused by wind or inaccurate erection, was not provided for. In connection with the construction of the Canal an Act was passed restricting the purchase of material and equipment to firms in the United States unless for special reasons the President decided otherwise. The Commission, however, found that the proposal of the German firm "was so much lower in price than any other, and the experience and reputation of this firm so excellent, that it was unquestionably the best of those received." In view of what has now happened it would be interesting to know if the Commission still hold the same views.

Concrete versus Earthworks for Fortifications.—The *Engineering Record of New York*, in a recent leading article, states that every war affords great scope for the skill of the engineer, and the present terrific struggle has already presented some questions of startling significance, reference being made to the gigantic tasks of transportation which are being performed. Not less in importance, however, are some other problems which demand immediate attention for efficiency and solution. One of these is to find the material of maximum effective resistance to high explosives. It seems to have been demonstrated effectively that concrete, which has been the main stand-by in modern fortifications, is almost useless in its customary form. The turrets of permanent concrete forts were rendered useless by a few rounds of shells charged with high explosives. From the photographs of the demolished works it appears that, even when the turrets themselves were not demolished, they were fairly blown off their foundation by the complete shattering of the concrete bases. On the other hand, temporary earthworks, and one or two forts heavily supported with earth, appear to have resisted attack by high explosives measurably well. A shell penetrating a few feet into concrete rends the whole mass, while in earth it merely opens a crater, which is partly filled in again by the falling dirt. It was noticed in the American Civil War that an active shovelling party could in a short time repair the damage of a heavy bombardment where an earthwork was concerned. The questions now to the front are whether any reinforcement of the concrete will be of service, or whether a proper choice of earth construction will so muffle the explosives as to make them comparatively ineffective. A few feet of loose dirt, or even of snow, will stop a bullet which would pierce a half-inch iron plate, and the same principle seems to hold good for heavy projectiles.

A Remarkable Wireless Station.—A powerful installation was recently opened by the Marconi Company for the Chilian Government at Punta Arenas, on the wild coast of Patagonia, in the Straits of Magellan, which is said to be the most southerly town in the world. The station is housed in a ferro-concrete building some three miles from the town, and contains a 100-kilowatt equipment for long-distance communication and a 5-kilowatt set for ship traffic, etc. Four distinct aerials are used, two for radiating different lengths of 100-kilowatt waves, one for the reception of long waves, and the fourth for the 5-kilowatt set. All are of the inverted L directive type, and are

supported on pulley blocks slung from porcelain insulators on 250-feet steel masts, so that an adjustable sag is allowed to prevent undue strain in heavy gales. Provision is made for passing current through the aerial wires to thaw them if covered with a dangerously heavy load of ice. The large generating plant is driven by a 270 horse-power Diesel engine, and develops 150 kilowatts at 200 to 360 volts continuous current. A 2,000 amperes-hour battery is also provided. The transmitting apparatus includes a condenser of 1·25 microfarads, made up of 416 Poldhu pattern pots of a new design charged at 10,000 volts, and a 36-inch radial disc discharger in a sound-proof chamber. Either 5,000 or 3,000 metre waves can be sent.

A Monster Locomotive Crane.—There is installed by the Browning Company of Cleveland, Ohio, at the New York Navy Yard, a locomotive crane which is the largest in the United States. Its main boom has a length of 85 feet and a capacity of 50 tons at the full radius. It handles big guns, armour-plate, boilers, and engines, which are used in the largest warships. A 38-foot extension boom is designed for the special purpose of handling the basket masts which are peculiar to the new Dreadnoughts. Formerly it was necessary to cut these masts in half, because there was no equipment of sufficient capacity to convey them as a unit. The new machine has ample stability for such work.

A Smart Piece of Military Engineering in Canada.—It is reported that Valcartier, Canadian Northern Railway Station, was recently transformed in less than two weeks into an important railway terminal with twenty miles of sidings. One of the items in the speedy construction work accomplished was the building of a pontoon bridge, to connect the main camp with the artillery practice-grounds belonging to the Royal Canadian Engineers. Work was begun on the bridge, which is 350 feet long, at eight o'clock in the morning and at ten minutes after noon the commanding officer was able to hurry a heavy gun across the completed structure. About 500 barrels were used in the construction of the bridge, which is of the pontoon type. The work was done by 300 men divided into squads, so that while one squad was making the barrels watertight another lashed them to heavy planks on which the superstructure rests, and still others carried the pontoons to the water's edge, floated them to position in the river or spiked down the superstructure. Simultaneously with the construction of the bridge a twenty-foot bank was graded down to afford an easy approach for the roadway. The builders were hampered by the large quantity of logs that were being carried down with the current, but no damage to the structure resulted. The work was carried out by the Royal Canadian Engineers, acting under the direction of Major W. B. Lindsay, of Winnipeg.

CORRESPONDENCE.

THE INDIAN INDIGO INDUSTRY.

In Sir Lewis Hay's letter to the *Journal* dated January 15th, he refers to the Japanese natural indigo industry in these words: "There is, or was up to a few years ago, a small indigo industry in Japan, but I do not know what method of extraction they employed."

As a matter of fact the industry still exists, though rapidly declining. The process employed for extracting the dye follows closely on the lines of the Chinese system, viz., by the use of lime in the steeping vats.

I have never heard of "replanting the steeped plants after extracting the dye," either in China or Japan, or even in the Loo Choo Islands, where probably the most primitive methods of indigo cultivation and dye extraction are employed.

In conclusion, I would refer anyone interested in the Japanese natural indigo industry to that very useful work "The Industries of Japan" (pages 173-176), by J. J. Rein (Hodder & Stoughton).

HENRY F. BRAY.

Tokyo Higher Commercial School,
Tokyo, Japan, February 20th, 1915.

THE HARDWOODS OF PANAMA.

The general article on the above subject in the *Journal* of February 26th gives some interesting facts; but I fear the writer has stated his case too loosely as to values, and unless expressed more clearly they can be of no guidance here, and are certainly misleading to the owners in Panama. As an instance, the article states that the lumber of "Guarea caoba" and "Carapa guianensis," is so similar to Honduras mahogany that it is equally valuable, about £18 per 1,000 ft. This does not indicate whether in log form, converted lumber, nor if the point of delivery is f.o.b. steamship or landed in England, or New York, or if the value is for standing lumber in the forest. To determine the value of proposal these are elementary points to know, and the nearness of lumber to a good river, so that it can readily be floated to seaboard, is an important factor when seeking a market. Your author gives the value of Panama hardwoods as over £98,000,000.

I will take the figure £18 per 1,000 ft. of the wood said to be equal to Honduras mahogany. If this is meant either standing in the forest or in log form, at the seaboard, the figures are misleading. I have before me offers of mahogany estates where the logs at seaboard would not cost one-third of this, so I will leave your readers to judge the value of trees in the forests; in fact, the expert opinion before me states \$2 per M feet as the value. Even if the author intended the values to be delivered at New York or London, they are too high; that

is overhead, the cost of logging, transportation to the seaboard, freight and landing charges, are serious items in this business, and faulty wood seldom makes freight and charges.

Wood has been intermittently shipped from Panama for many years, but unfortunately it arrives frequently seriously shaken, and is liable to be wormy, so that it has not commanded the universality of demand which is accorded to other shipments of mahogany.

There is certainly much in the article which needs explanation, especially if the author wishes to get the timber of Panama on to either the European or New York markets.

FRANK TIFFANY.

Leamington Spa, March 19th.

OBITUARY.

SIR JOHN CAMERON LAMB, C.B., C.M.G.—By the death of Sir John Lamb, which took place at his residence in Hampstead on March 30th, the Council has lost a highly valued member. Sir John joined the Society in 1892. In 1906 he was elected a member of the Council, in which capacity he served till 1909. During the year 1910–11 he was Chairman of the Council, and from that time till his death he continued a Vice-President of the Society. In 1910 he read a paper on "The Lifeboat and its Work," in which he worked out very carefully and exhaustively the question of the invention of the lifeboat. The Society of Arts in 1802 awarded a gold medal and a sum of fifty guineas to Henry Greathead, of South Shields, for its invention; but Sir John Lamb came to the conclusion, after very full research, that the rewards should have been given to Lionel Lukin, of Long Acre.

The subject of his Chairman's address, which opened the Session 1910–11, was the part played by the Royal Society of Arts in assisting the development of telegraphy. This was a question on which his official position at the Post Office entitled him to speak with authority, and he certainly made out a very good case for the Society. In addition to contributing these two papers to the Society's records, Sir John presided at several meetings and took part in discussions on various occasions.

Sir John Lamb was born in 1845. He entered the Post Office in 1864, became Assistant Secretary in 1889, third Secretary in 1896, and second Secretary in 1897, an office which he held till his retirement in 1905. He was chairman of many departmental and inter-departmental committees; he acted as British delegate to international conferences for the protection of submarine cables, which were held in Paris in 1886; he represented Britain and the Cape and Natal at the International Telegraph Conference held at Paris in 1890, and at Buda-Pest in 1896; and he presided over the Conference in London in 1903. He was the senior British delegate to the Conference on Wireless Telegraphy at Berlin in the same year; and he acted as chairman of the Government Committee to inquire into Injuries to Submarine Cables by Trawlers, which reported in 1908.

In addition to his other duties, Sir John Lamb took a very deep interest in the work of the Royal National Life-boat Institution, of which he was Vice-President and Deputy Chairman at the time of his death. He was also President of the British Consultative Council of the Hungarian Society.

In acknowledgment of his public services he was awarded the honour of C.B. in 1895, of C.M.G. in 1890, and he was knighted in 1905. He also received a number of foreign decorations.

GENERAL NOTES.

THE WILD CITRUS FRUITS OF MADAGASCAR.—Citrus fruits grow in a wild state in Madagascar, though in the centre and on the east coast of the island oranges and mandarins are grown in small quantities from planted trees. Oranges and lemons ("voasary" in Malagasy) of no fixed varieties are most common on the east coast, and are found either near the shore in sandy soil or more in the interior in compact soil, more or less flinty or rocky, and as a rule poor and arid. The trees do not grow in the shade of forests, but are scattered among bushes, usually next to guava and "voavontaka" (*Strychnos ipcnosa*) trees. The quality of the fruit, excepting the lemons, is generally poor. There is an orange tree (*Citrus aurantium*) on the west coast which contains little juice, and is attacked by a small larva which eats the pulp. The tree is also attacked by a larva or moth which devours the leaves completely. A small lemon ("voasary makirana" in Malagasy), about the size of a hen's egg, also grows on the north-west coast. On the east coast there are two local varieties of mandarins, and one imported variety from Zanzibar. Grape fruit or shaddock of an imported variety is found on the east coast. Semi-tropical fruits, such as mangoes, figs in small quantities, pomegranates, etc., also grow in Madagascar, but not in a cultivated state, except at the experiment stations at Tamatave and Nanisana.

NEW METHOD OF HATCHING SILKWORMS.—A new method of hatching silkworms is reported to have been perfected in Aichi Ken, Japan. The method is very simple. Egg cards are immersed in dilute hydrochloric acid for five to ten hours just before they are hatched. In a fortnight or twelve days after the immersion the eggs are perfectly hatched, and worms that are stronger and more healthy than those hatched in any other way may be seen coming out of the shells. The silk produced by the worms thus hatched is better and longer than that produced in any other way. It has been stated that the silk produced by the

worms bred in the newly-invented way measures 1,200 ft., whereas the thread produced by the worms hatched in the ordinary way measures only 700 ft. at the longest. It has been further stated by the inventor that anyone can make use of the new process, which, although declared by the American Consul at Yokohama to be worthy of being fully protected, will not be patented, as the inventor's sole desire is to strengthen Japan's position as a silk-producing country. The inventor is Mr. Kawahito, the Director of the Aichi Ken Sericulture Experimental Station.

The Internal-combustion Engine on the Oil Field.—In the course of a paper on this subject, read before the Institution of Petroleum Technologists by Mr. F. G. Rappoport, attention was drawn to the fact that the oil engine has created a large and important sphere of its own by facilitating profitable operation in certain wells which have a small yield. Each well had formerly to be closed, but the low fuel-consumption of the oil engine has rendered it possible to work them. The oil engine is admirably adapted for outlying districts and for prospecting work. In the Binagadi oil field, which has no adequate water supply, and in the new Ural and Biellik districts in Russia, it is very widely used. The only defects of the system as used at the present time are decentralisation and want of flexibility in transmission of the power.

The Tali-pot Palm.—A short account of the tali-pot palm (*Corypha umbraculifera*) is contained in the January number of the *Indian Forester*. The tree is indigenous in the Andaman Islands and Southern India, where it is put to many uses. The pith is used for flour, some thirty headloads being obtained from one tree. The leaves serve for umbrellas and thatching, and the seeds are converted into buttons. At Hanowar bats live under the shelter of the tali leaves, and when the lendi fruit (*Calophyllum inophyllum*) is ripe they bring back large quantities to their palm and drop the hard drupes. These contain oil, which is much valued, and the natives are, therefore, planting the tali-pot palm in order that they may obtain oil in this easy manner.

Canadian National Exhibition.—The Imperial Trade Correspondent at Toronto (Mr. F. W. Field) reports that the Canadian National Exhibition will be held in that city as usual this year during the last week in August and the first week in September. Mr. Field remarks that this Exhibition is considered to be one of the best annual exhibitions held on the American Continent, and there are indications that great interest will be taken in it this year despite the war and that a large number of manufacturing, machinery and miscellaneous exhibits will be made. Any British firms desiring space at the Exhibition should make early application to Dr. Orr, Secretary of the Canadian National Exhibition, City Hall, Toronto, from whom further particulars may be obtained.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

April 14. — T. Thorne Baker, "The Industrial Uses of Radium."

April 21.—Moreton Frewen, "The State and the Fisherman."

April 28.—A. S. E. Ackermann, B.Sc., Assoc. M.Inst.C.E., "The Utilisation of Solar Energy."

May 5. — Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., "On the Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate."

May 12.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry." Sir Robert Abbott Hadfield, D.Sc., F.R.S., will preside.

Additional Lecture.

Thursday afternoon, at 4.30 o'clock :—

May 6.—M. Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Constantin Meunier et les Sculpteurs Belges de son Temps."

Indian Section.

Thursday afternoons :—

April 15, at 5 p.m. — Perceval Landon, "Basra and the Shatt-ul-Arab." The Right Hon. Earl Curzon of Kedleston, G.C.S.I., G.C.I.E., will preside.

May 13, at 4.30 p.m.—Sir Charles H. Armstrong, late Chairman, Bombay Chamber of Commerce, "Indian Trade and the War."

Colonial Section.

Tuesday afternoon, at 4.30 o'clock :—

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials." The Hon. Sir George H. Perley, K.C.M.G., Acting High Commissioner for Canada, will preside.

Date to be hereafter announced :—

C. H. Sherrill, "Ancient Stained Glass."

Cantor Lectures.

Monday evenings, at 8 o'clock :—

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Journal of the Royal Society of Arts.

No. 3,255. VOL. LXIII.

FRIDAY, APRIL 9, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

NEXT WEEK.

WEDNESDAY, APRIL 14th, 8 p.m. (Ordinary Meeting.) T. THORNE BAKER, "The Industrial Uses of Radium."

THURSDAY, APRIL 15th, 5 p.m. (Indian Section.) PERCEVAL LANDON, "Basra and the Shatt-ul-Arab." The RIGHT HON. EARL CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., will preside.

Fellows are requested to note that this meeting will be held at 5 p.m., instead of the usual hour, 4.30.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

ALDRED LECTURE.

A meeting of the Society, under the terms of the Aldred Bequest, was held on Thursday, March 11th, 1915; LORD SANDERSON, G.C.B., K.C.M.G., in the chair.

THE CHAIRMAN, in opening the meeting, said that the late Dr. Aldred, a former member of the Society, left a bequest of £100 to be devoted to obtaining essays or lectures upon scientific and literary subjects. The money was invested, but it was only at occasional intervals, when the income had attained sufficient proportions, that the Society was able to use it, and on those occasions some subject had to be chosen for the lecture which it was thought was likely to be of general interest. It was a matter of common observation that people of ordinary education knew a good deal more about the distant events of history than they did of those which took place in the time of their grandfathers, and equally, in regard to Art, people knew a good deal about the artists and the pictures of the Renaissance down to the end of the seventeenth century, while of modern Art outside their own country they knew little or nothing. Circumstances of a painful character had recently drawn a great deal of attention to, and excited their interest in, Belgium, and those who, like himself, had gone to the recent Exhibition of the Royal Academy, would probably have been struck by finding how very little they knew of the modern schools of painting and sculpture which had grown up in Belgium since the time it had a separate existence in 1830. Everyone had some elementary knowledge of the old Flemish school; the names of Van Eyck, Mabuse, Memling, Rubens, Van Dyck, Snyders and Teniers were probably familiar to most people, but of the later painters they knew very little. The Society was fortunate in having been able to secure the assistance of M. Paul Lambotte, the eminent Director of Fine Arts in the Belgian Ministry of Science and Art, to illuminate their ignorance on the subject, and he would ask him to deliver his lecture.

The lecture delivered was—

L'ÉVOLUTION DE L'ÉCOLE BELGE DE PEINTURE (1830-1900).

Par M. PAUL LAMBOTTE,
Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique

Mesdames, Messieurs,—

Je me suis laissé dire que notre école belge du dix-neuvième siècle n'est qu'imparfaitement connue en Angleterre.

Et bien volontiers j'ai répondu à l'invitation si flatteuse de la Royal Society of Arts qui m'a demandé une causerie sur ce sujet.

Je ne puis vous parler, dans ce court espace d'une heure, du développement *de l'art* en Belgique pendant trois quarts de siècle. Il faudra bien laisser de côté aujourd'hui et la sculpture, dans laquelle cependant nos artistes ont excellé pendant la seconde moitié du dix-neuvième siècle, et l'architecture, qui a sa physionomie et son originalité chez nous, et la musique, qui prêterait à développement, et l'art décoratif, et bien d'autres choses encore.

En me bornant à vous entretenir de la peinture et des peintres, ou plutôt *de l'évolution de la peinture en Belgique*, j'aborde déjà un sujet beaucoup trop vaste et complexe. Je ne pourrai vous donner que des aperçus et des résumés.

Car nous avons eu et nous avons encore en Belgique un très grand nombre de peintres de beaucoup de talent et, à moins de vous réciter une sorte de catalogue, je n'aurai même pas le loisir de vous dire tous les noms marquants.

Je préfère tenter de vous expliquer quelles furent les tendances successives ou simultanées de notre peinture et vous montrer comment, dans un pays qui n'a pris conscience de sa personnalité qu'au moment où il a obtenu son indépendance avec un régime politique conforme à ses aspirations, les influences étrangères, tout à fait préponderantes d'abord, ont bientôt disparu sous la poussée d'une sorte de renaissance vraiment autochthone et locale, logique en somme, si l'on considère les traditions et les goûts de la race.

Cette étude m'amènera chemin faisant à vous entretenir des artistes qui ont apporté dans la peinture de notre pays quelque chose de personnel et de neuf, qui ont marqué comme chefs de groupes, ou comme individualités isolées, dont la personnalité a eu de l'influence sur le développement général de l'école.

Vous connaissez les œuvres de quelques-uns de nos peintres. Vous avez lu leurs noms, vous avez vu leurs œuvres. Un Leys, un Gallait, un Wiertz, un Alfred Stevens ne sont pas pour vous des inconnus.

Mais avez-vous songé qu'une école qui a produit ces maîtres doit compter *autour d'eux* un grand nombre d'artistes excellents ? Ces maîtres ne sont pas des exceptions, des étoiles isolées. Ils tiennent au milieu, au pays, à l'école.

Les circonstances ont fait que vous n'avez pas eu, en Angleterre, l'occasion de voir leurs œuvres et de les étudier. Il faut pour cette étude se rendre à Bruxelles, à Anvers, à Gand, à Liége, suivre dans les musées de ces villes le développement de la peinture en Belgique. J'ai parlé l'autre jour, non loin d'ici, d'Alfred Stevens, peintre de la Parisienne du second Empire. Mais j'ai pris la précaution d'éviter d'isoler le peintre de ses confrères. J'ai comparé notre école à une forêt touffue, compacte, pleine d'arbres de belle et saine venue. Alfred Stevens n'est que l'un d'eux. Beaucoup d'autres l'entourent.

Mais ces artistes, par suite de circonstances diverses, n'ont jamais participé aux expositions anglaises, ils ne sont représentés ni dans vos musées ni dans vos collections.

Tandis que le musée du Luxembourg à Paris ou le musée municipal de Venise sont riches en œuvres de l'école belge, les galeries britanniques n'en contiennent que peu ou pas. J'oublie les galeries d'Allemagne et d'Autriche qui en fourmillent. En ce moment, grâce à la munificence de M. Edmund Davis, qui a dépouillé sa maison au profit d'une entreprise charitable, vous pouvez admirer quelques belles pages d'Alfred Stevens à la French Gallery dans Pall Mall—et même vous pouvez constater que ses toiles ne sont nullement déplacées à coté des chefs-d'œuvre des diverses écoles et des diverses époques avec lesquels elles voisinent. Même elles vont et "tiennent" très bien avec deux merveilleux "Whistler," sur le même panneau ! C'est là un fait que je puis mettre en lumière avec un légitime et patriotique orgueil. Mais évidemment, je le répète, une école qui compte ce Stevens compte aussi beaucoup d'autres peintres non moins intéressants. Seules les circonstances ont fait que vous ne les connaissez pas.

La faute en est à l'indolence de nos artistes, qui ne tentèrent rien pour exposer à l'étranger. A part une exposition organisée au Guildhall, en 1900, par les soins du très distingué M. Temple, avec mon concours, je ne crois pas que les amateurs britanniques aient eu l'occasion de voir un ensemble d'œuvres belges du dix-neuvième siècle, un ensemble de pages maîtresses des peintres dont je vous dirai tout à l'heure, peu à peu et chemin faisant, les noms principaux.

Sans nul doute vous connaissez beaucoup mieux l'école hollandaise de la même période et vous pouvez vous étonner de cette différence entre des peintres contemporains les uns des autres et qui, à première vue, semblent devoir vous être aussi familiers les uns que les autres.

Israels, les frères Maris, Bosboom, Mesdag, Mauve, Bakkerkorf : voilà des noms qui représentent à vos yeux de beaux talents, de nobles œuvres, des peintures de prix aussi.

Mais vous ignorez Henri de Braekeleer, Alfred Verwée, Louis Artan, Joseph Stevens, Hippolyte Boulenger, Eugène Smits et bien d'autres qui, croyez moi sur parole en attendant de pouvoir vérifier cette assertion, valent bien les premiers et même valent souvent mieux que les premiers parce qu'ils n'ont pas travaillé pour le *commerce*. Pourquoi cette difference ?

Mon Dieu, mesdames et messieurs, c'est bien simple et nous n'y insisterons pas. C'est une question de marchands, tout simplement. Les artistes hollandais ont eu la chance d'avoir des marchands habiles qui ont su faire valoir leurs ouvrages, rendre leurs noms célèbres en dehors de leur patrie, leur maintenir ouvert le

marché français, le marché anglais, le marché américain.

Cela a manqué aux Belges, et les collectionneurs n'ont pas été assez avisés pour se passer de ces intermédiaires et acheter—oh, pas bien cher dans ces conditions—des œuvres qui, dans quelque vingt-cinq ans, seront extrêmement recherchées, vaudront leur pesant d'or.

Mais cela n'a aucun rapport avec leur qualité d'art et leur mérite. Ce n'est qu'une question de gros sous et de patience !

L'histoire de la Belgique, royaume indépendant, commence, vous ne l'ignorez pas, en 1830, au moment de notre séparation violente—de notre divorce de raison—d'avec la Hollande. L'histoire de la peinture en Belgique commence en même temps. On peut dire que depuis Rubens et le groupe de ses élèves au dix-septième siècle—sous le gouvernement prospère et suffisamment respectueux du principe des nationalités de l'archiduc Albert et de l'infante Isabelle l'art a subi une longue et trop totale éclipse. Après 1830 il refleurit.

Nous constatons tout d'abord la prédominance d'influences étrangères. Évidemment elles ne peuvent venir que de France, et c'est David - David le régicide, qui a résidé à Bruxelles en proscrit—qui les a introduites et répandues. Jean François Navez, un Belge, le meilleur élève de David, a subi complètement son ascendant et recueilli avec ferveur ses enseignements. Il devient le chef de notre école, le directeur de l'Académie de Bruxelles, le professeur des jeunes générations. Il a vécu longuement à Rome et à Paris ; il a admiré passionnément Raphael et Andrea del Sarto. Il revient tout féru de classicisme et ne rêve que " grand art," c'est à dire peinture religieuse et peinture d'histoire. Autour de lui tout un groupe se forme. On veut de grandes compositions, des scènes réunissant de très nombreux personnages de grandeur naturelle. Et ces scènes ne peuvent pas être empruntées à la vie quotidienne. On veut de la peinture à costumes, de la peinture à tirades qui fait penser aux drames romantiques, à Victor Hugo, à Dumas père. La jeune Belgique de 1830 a toute un pleïade de peintres qui fait du biblique, de l'historique, de l'allégorique.

J'ai nommé Navez ; il y a De Biefve, auteur du " Compromis des Nobles " ; il y a Decaisne, qui peint une " Belgique couronnant ses enfants illustres " ; il y a Nicaise De Keyzer, qui peint la bataille de Woeringen ou la bataille des Éperons d'Or ; il y a Slingeneyer, qui peint la bataille de Lépante : et cette spécialité met dans nos musées comme un rappel de la Galerie des batailles à Versailles. Elle nous donnera plus tard l'Abdication de Charles Quint, de Louis Gallait, et plus tard encore Pierre l'Ermite prêchant la croisade, de Gustave Van Aise, les peintures décoratives d'Alfred Cluysenaar et d'Émile Delperée.

Sans doute, mesdames et messieurs, je sais bien que cet art est démodé, que ce n'est pas beaucoup de la peinture, que cela manque de tout ce que les vrais peintres ont introduit de plasticité, de sensibilité, d'impressionisme dans l'art. C'est froid, c'est figé.

Mais il faut bien reconnaître d'autre part que ces " vastes machines " résument une belle éducation technique. C'est composé, c'est dessiné, c'est exécuté. Quand on voit l'impuissance où se débattent maintenant tant de peintres quand il s'agit d'agencer un groupe ou de construire même une figure, on ne peut se tenir de rendre justice aux grands ancêtres qui *savaient* si bien tout ce qu'il faut savoir, sauf à mal utiliser ce savoir.

Seulement ces peintres, qui étaient peintres de figures, ont peint, par délassement ou gagne-pain, beaucoup de portraits. Et dans ces portraits ils sont évidemment très forts ; observateurs de la nature avec une simple et saine conscience, ils ne cherchent pas à en faire accroire et paient comptant, sans escamotages.

Le vieux Navez, comme son maître David, nous a laissé des portraits magnifiques. Nous ne regardons plus ses tableaux religieux ou ses anecdotes historiques, mais nous commençons à rechercher et à collectionner ses portraits. Il y a des groupes, parfois six ou huit personnes de grandeur naturelle réunies sur la même toile, qui sont remarquables.

Voici la " Famille de Hemptinne " ; elle est au Musée de Bruxelles. En outre de ses mérites d'agencement et de style, dont vous pouvez juger malgré l'imperfection de cette reproduction, cette toile a des qualités de couleur à la fois fortes et rares qui ne peuvent passer inaperçues.

Je dois demander l'indulgence pour la serie d'illustrations qui éclairera ma causerie ce soir. Par suite des circonstances douloureuses que nous traversons, je n'ai rien pu faire venir de Belgique ; il a fallu se contenter de reproduire des images prises dans des livres. Il y a beaucoup de lacunes. Je vous montrerai une série très incomplète de projections qui ne donnent qu'une idée très faible et parfois désastreuse des œuvres qu'elles devraient représenter. Mais vous m'excuserez et votre imagination suppléera ce qui manque.

Ce portrait de Hemptinne est déjà un premier gage d'un retour à l'observation de la nature, à la sincérité, à la simplicité, par réaction contre les conventions de l'académisme de David. C'est le commencement des conquêtes du sens réaliste inhérent à la race, rejetant les influences étrangères qu'il n'a pu s'assimiler.

D'ailleurs l'apparition même des grandes compositions dont je vous citais, il y a un instant, les principales, a suscité très vite d'autres réactions, a provoqué des querelles fécondes.

Le Baron Wappers a pris la tête de ce mouvement de retour à l'observation de la nature. Voulant peindre lui aussi une grande composition d'histoire, il a choisi cet "Épisode de la Révolution," et montré des contemporains en costumes contemporains. On a beaucoup discuté, ergoté, épilogué. Chaque tendance a gardé ses partisans, toutes deux ont coexisté longuement et toutes deux finalement ont disparu par un autre retour de la mode pour faire place à d'autres recherches.

Je veux vous dire quelques mots d'un homme qui a occupé, et occupe encore, une place isolée dans l'école, un homme en qui le Gouvernement Belge et le grand ministre Rogier ont cru profondément, un homme qui est consacré à Bruxelles par un musée de ses œuvres que tous les étrangers vont voir.

Wiertz, Dinantais un peu hâbleur, a fini par se persuader qu'il avait retrouvé les pinceaux de Rubens, et que dans la suite ininterrompue des artistes se passant symboliquement le flambeau de main en main il avait reçu du Maître directement le précieux don !

Wiertz est un philosophe grandiloquent, un chercheur curieux, mais il n'a, en fait, aucun instinct de la plasticité. Son dessin est emphatique ; il n'a ni style ni rythme ; sa couleur a des rapports faux ; il n'a pas le sens de l'harmonie.

Je concède volontiers que ses grandes compositions, "Les Grecs et les Troyens se disputant le corps de Patrocle" ou le "Christ et l'Humanité," offrent un certain intérêt, mais cela est tout ce que vous voudrez—excepté de la peinture ! Et quand Wiertz veut peindre "un morceau," un portrait par exemple, d'après nature, on sent à la fois son impuissance et son dédain orgueilleux.

Je vous parlais il y a un instant des beaux portraits de Navez et de ses contemporains.

Il est un peintre de cette époque dont je me plais à évoquer un instant la figure déjà devenue mystérieuse et lointaine. François Simoneau, tel est son nom, est représenté au Musée de Bruxelles par deux œuvres de grande valeur, et nous connaissons un portrait de lui chez la fille du peintre de marines Clays. Nous savons que Simoneau fut formé à l'Académie de Bruges, qu'il a travaillé à Paris avec le Baron Gros, et qu'après un court séjour à Bruxelles il s'est fixé à Londres où il a achevé une carrière qui paraît n'avoir point été heureuse. Il y est mort en 1859. On retrouve trace de l'apparition de ses portraits aux salons de la Royal Academy et à des expositions diverses. Mais à chaque nouvelle apparition le peintre réside à une adresse nouvelle. Il descend vers les quartiers humbles, il est visiblement un homme qui ne réussit pas, que la gêne d'abord, la misère ensuite ont étreint. J'ai vainement cherché à retrouver en Angleterre des portraits de François Simoneau, et M. Marion H. Spielmann, votre érudit critique d'art, a bien voulu tenter de m'y aider sans y avoir réussi plus que moi, malgré sa bonne grâce obligeante. Les trois peintures jusqu'à présent uniques—conservées à Bruxelles, aiguisent mon désir d'en voir d'autres. Elles semblent apparentées aux œuvres de Sir Joshua Reynolds ou de Sir Thomas Lawrence. Je me demande si déjà les meilleures de celles qui furent peintes en Angleterre n'ont pas changé d'état civil et augmenté le catalogue des œuvres d'autres peintres britanniques "qui se vendent bien" ? Je serais reconnaissant à tous ceux qui connaîtraient ici des peintures de François Simoneau de me les indiquer.

Nous n'avons pas eu seulement en Belgique des peintres d'histoire qui peignirent—accessoirement—des portraits. Nous avons eu aussi des portraitistes exclusivement adonnés à cette spécialité.

Le plus éminent fut Liévin De Winne, qui fut essentiellement l'historiographe d'une société intellectuelle et un peu puritaine. C'est un peintre de la vie intérieure, sachant ne jamais se parer des prestiges d'une technique cependant très savante et très expérimentée. Je dirai que Liévin De Winne fut le peintre des grands bourgeois, hommes politiques, hommes de science, professeurs, magistrats. Beaucoup de ses portraits sont psychologiques, profondément, et bien avant le trop fameux Lenbach, avec une sincerité toute simple, De Winne a sacrifié à l'expression des visages tout le pittoresque un peu facile des arrangements de costumes et de décors. Les portraits de Liévin De Winne sont graves, ressentis ; ils n'attirent pas les regards, mais ils les retiennent intensément dès qu'ils les ont fixés. Les fonds sont neutres,

les vêtements noirs et discrets, et même dans les portraits de femmes il n'y a pas de concessions à l'effet, à la mode. Non, seuls les visages, traités avec un art qui ne s'affiche pas, respirent, pensent, avèrent des individualités originales.

Nos musées belges ont commencé de recueillir des portraits de L. De Winne. Quand les familles des modèles s'éteignent ou se dispersent le moment des musées arrive. Nous avons fait cela à Bruxelles pour Navez et pour De Winne. À Gand, ville natale de l'artiste, toute une série de ses œuvres a été groupée déjà au musée

Il est un peintre qui a conquis dans notre école une place prééminente et dont l'influence a été considérable, même hors de Belgique. J'ai nommé le Baron Henri Leys, qui fut l'initiateur de tout un mouvement d'art. Il a formé des disciples éminents. Directeur de l'Académie d'Anvers, il fut le maître d'Henri de Braekeleer et de nombreux peintres belges remarquables. Il fut aussi, et la gloire n'est pas mince, le maître d'Alma Tadema, ce Hollandais qui devait devenir un grand Anglais, et de James Tissot, Américain, je crois, que la France a adopté.

Leys a rompu avec la tradition des peintres d'histoire qui se recommandaient, à la suite de Navez, de la Renaissance italienne. Avec une prescience curieuse il est remonté aux influences des maîtres primitifs de la Flandre et de l'Allemagne. Il s'apparente, sans pastiche, à Holbein et à Cranach. Il ne les imite pas, il ne les continue pas, il peint comme s'il était l'un de leurs contemporains, avec un sens du passé qui confond l'entendement.

Leys paraît retrouver la vision d'autrefois comme si la mémoire d'une existence antérieure ranimait les scènes abolies sous ses yeux. Les personnages qu'il met en œuvre ne sont pas des modèles costumés plus ou moins à l'aise dans des oripeaux de hasard. Ils ne posent pas. Ils vivent leur vie, à l'aise, sans anachronisme, dans le décor authentique, le milieu exact de leur temps. Les habits vont aux corps, aux habitudes de l'être, tout est plausible, harmonieux. Leys est un évocateur qui paraît retrouver dans les profondeurs d'un passé lointain des visions fidèles et complètes. Avec cela il est peintre de race, coloriste à la manière des vieux maîtres du pays, somptueux et brillant.

En outre d'une nombreuse série de tableaux de chevalet, Leys a laissé deux ensembles de compositions monumentales qui assurent la pérennité de sa gloire: les panneaux de la grande salle de l'hôtel de ville d'Anvers et ceux qu'il avait peint pour la décoration de sa propre salle à manger et qui, après son décès, ont été transportés eux aussi à l'hôtel de ville d'Anvers. On a détaché très habilement les fresques des murs et on les a disposées, conformément aux conceptions de Leys, dans une salle de dimensions analogues. Leys avait peint à l'huile des répliques de tous ces panneaux. Les Musées de Bruxelles et d'Anvers et divers collectionneurs se glorifient de les posséder. L'un d'eux, acheté par le sénateur américain Vanderbilt, est encore en exil quelque part à New-York.

Toute une école a suivi les enseignements de Leys, mais dépourvus de son curieux instinct d'archaisme ses imitateurs ont été en affaiblissant l'effet de ses découvertes.

Cependant la grande salle échevinale de Bruges, décorée par Albert de Vriendt, l'escalier de l'hôtel de ville d'Anvers, orné de panneaux peints par divers élèves de Leys, la salle des mariages à l'hôtel de ville d'Hoogstraeten et quelques autres ensembles ne sont point négligeables.

Dans un autre esprit et, je dirai, une autre formule, et pour achever la revue des grandes compositions monumentales, je dois citer encore les peintures de la Halle aux draps à Ypres, que les obus incendiaires des armées de Guillaume II. ont si lamentablement et inutilement détruite Pauwels avait peint sur ces murs des compositions intéressantes, mais un autre artiste, Louis Delbeke, y avait consacré toute sa vie et tout son art. L'ensemble de cette décoration évoquait une belle et originale figure d'artiste.

Ces peintures n'étaient pas très connues, Ypres étant éloigné des centres et mal desservi par le chemin de fer. Sans doute on y allait en automobile, mais combien d'excursionnistes ont su apprécier cet art singulier et savoureux auquel tous les artistes rendaient hommage ?

L'autre jour encore votre grand maître décorateur, Frank Brangwyn, me parlait avec admiration de l'œuvre de Delbeke, et ensemble nous avons deploré avec une tristesse profonde, la disparition définitive, irrémédiable, de tout ce qui devait assurer à cet homme, mal apprécié et connu, les revanches de la célébrité future. Hélas . . . la pauvre Flandre, la pauvre Belgique, meurtries, écrasées, brutalisées, ont perdu bien d'autres trésors d'art, c'est leur destin historique d'être sacrifiées et depouillées, mais de se relever toujours ensuite et de créer de nouvelle beauté !

Louis Gallait a occupé une place très importante dans notre école. Il fut en quelque sorte le peintre officiel de la Belgique et son ambassadeur

artistique à l'étranger. Son "Abdication de Charles Quint" et, surtout, "Les Derniers Honneurs rendus aux Comtes d'Egmont et de Horne" (les têtes coupées) lui ont valu une notoriété européenne. Il est représenté dans beaucoup de musées et c'est à lui que le gouvernement a commandé des panneaux décoratifs pour la salle du Sénat, les portraits du Roi Leopold II. et de la Reine Marie Henriette et bien d'autres choses.

Charles Hermans est l'auteur d'un tableau célèbre intitulé "A l'Aube," qui, en outre de ses rares mérites de peinture, offre un intérêt quelque peu social. Hermans, qui vit encore, et n'a jamais cessé de travailler dans la méditation et l'isolement, laissera un œuvre très important et curieux, encore mal connu et apprécié.

Alfred Cluysenaar a décoré de grandes pages d'histoire violentes et hautes en couleurs le grand escalier de l'Université de Gand.

Emile Delperée a peint à Liège des compositions illustrant l'histoire locale. J'ai la bonne fortune, grâce à l'obligeance de M. Clifford Smith, de pouvoir vous montrer une esquisse excellente de Delperée, qui résume les qualités de ses œuvres définitives.

André Hennebicq est l'auteur d'autres panneaux placés dans les hôtels de ville de Louvain et de Tournai.

Enfin un homme qui s'est acquis en Belgique une situation prépondérante, et qui maintenant vit à Paris, Émile Wauters, est l'auteur de grands tableaux d'histoire qui ont renouvelé le genre en y introduisant, avec un souci curieux de la réalité et de la simplicité, des éléments de pittoresque et une saveur d'exécution très personelle. Il faut voir au Musée de Bruxelles et dans l'escalier d'honneur de notre hôtel de ville, ces compositions qui s'éloignent autant de Navez ou de Gallait que de Leys, et qui respirent un ardent amour de la vie.

Alfred Cluysenaar, Delperée, Hennebicq, Jean de la Hoese, Jean G. Rosier et Wauters principalement ont peint un grand nombre de portraits. Ils nous ont dotés d'un panthéon de célébrités non seulement locales mais cosmopolites.

L'hôtel de ville de Bruxelles, la salle des séances du Sénat de Belgique, les Musées de Bruxelles et de Gand montrent des décorations importantes et très originales exécutées par le Comte Jacques de Lalaing, peintre et sculpteur à la fertilité prestigieuse, à l'invention intarissable.

Léon Frédéric, plus spécialisé dans les tableaux de chevalet, a peint pour la salle de milice de l'hôtel de ville de Bruxelles un important panneau, "Le Départ des Conscrits," montrant la jeunesse d'un village partant pour la caserne au moment des moissons. C'est une page d'une profonde humanité, rustique, familière, éternelle.

En suivant le développement d'une lignée de peintres adonnés à la même spécialité, j'ai descendu le cours des années sans tenir compte de contemporains auxquels il faut que je revienne. Je viens de vous parler des peintres encore vivants, et même jeunes, relativement, quoique notoires. Je remonte vers le passé pour rejoindre d'autres peintres de figures—Alfred Stevens, Charles de Groux, Henri de Braekeleer, Eugène Smits, qui furent des hommes de premier plan, je veux dire des hommes qui seraient au premier plan dans toutes les écoles d'Europe et qu'une notoriété universelle consacre déjà; et puis Madou, Florent Willems, Portaels, Édouard Agneessens, qui ont leur importance chez nous et qu'on ne peut omettre.

Alfred Stevens est le plus connu, le plus étudié. Il fit à Paris la majeure partie de sa carrière et, comme je le disais il y a un instant, les grands collections d'Europe et d'Amérique, tous les musées, ceux de Bruxelles et d'Anvers principalement, mais aussi le Luxembourg à Paris, et la Pinacothèque de Munich, et la galerie de Buda-Pest, et le Musée de Marseille et celui de Liége, et le Metropolitan de New-York et bien d'autres montrent en bonne place ses pages d'exécution parfaite, dignes des plus appréciés d'entre les petits maîtres hollandais. Je vous remémore vite, sur l'écran, quelques-unes de ces pages charmantes et fortes.

Charles de Groux est moins connu hors de Belgique. C'est un peintre ému de la vie des humbles, un réaliste qui toujours cependant fait preuve d'un sens pathétique de la poésie élémentaire de la nature. Ses tableaux ne sont pas déclamatoires, ils ne prêchent pas, ils persuadent la grande pitié pour les pauvres, les souffrants.

De Groux a débuté comme peintre d'histoire. Lui aussi a exposé d'abord de grandes pages, une "Mort de Charles-Quint," un "Prêche dans une cave sous la réforme," que nos musées abritent. Mais il est devenu lui-même plus tard, quand il nous a révélé, avec un dessin parfois un peu gauche, mais un sens si exquis de la beauté de la vie et de la couleur, les scènes simplement poignantes dont il s'est fait une spécialité.

Voici "Le Bénédicité," d'une tranquillité si imposante, et cette "Scène de Cabaret," si touchante dans sa réalité pitoyable.

Charles de Groux fut l'ami et le maître de

notre grand Constantin Meunier. C'est près de lui que Meunier a trouvé au début un confident pour ses rêves, des encouragements pour ses essais. Simple et pathétique dans l'extériorisation de ses conceptions, Meunier a longtemps recherché des modes d'expression adéquats. Il a tenté toutes les expériences, éprouvé tous les procédés. C'est, en somme, le grand statuaire que l'humanité d'aujourd'hui a compris et aimé, mais nous avons en Belgique les traces des deux carrières successives du maître, celle du peintre, qui fut discutée, celle du sculpteur, qui ne parvint à la notoriété qu'après la soixantaine sonnée et pour si peu d'années de sérénité enfin acquise après les traverses d'une vie qui fut un Calvaire.

Henri de Braekeleer est un peintre d'Anvers qui fut le neveu et l'élève favori de Leys. Son œuvre n'est guère connu hors de Belgique. Il n'a pas laissé un très grand nombre de peintures parce que chacune fut longuement réalisée par un travail appliqué et patient.

Encore une fois il faut venir aux Musées de Bruxelles et d'Anvers étudier cet intimiste qui sut réaliser des harmonies si imprévues et si rares et exprimer par le plus simple décor, par des figures populaires et banales, une conception de la vie si tranquille, si enfermée dans un petit cycle moral. C'est un matérialiste ému par la couleur, les harmonies sourdes et somptueuses de la lumière sur les choses, un homme tout à fait isolé et à part dans toutes les écoles.

Voici de ses œuvres, mais combien affaiblies et incompréhensibles dans ce résumé photographique. C'est la polyphonie de Wagner réduite pour le piano, ou moins encore. J'ai trouvé au Musée de South Kensington, parmi les œuvres intéressantes léguées par M. Ionides, un petit paysage d'Henri de Braekeleer qui pourrait donner envie de voir des choses plus importantes et plus caractéristiques de ce peintre.

Eugène Smits, peintre de Bruxelles, mort il y a deux ans seulement, n'est pas connu encore selon ses mérites. Sa peinture est celle d'un être exquis, d'un être sensible à toutes les élégances morales, à toutes les influences de la beauté. Nous avons au Musée de Bruxelles son prestigieux "Cortège des Saisons" :—

"Cortège harmonieusement rythmé dans lequel la jeunesse fleurie du printemps, enveloppée de voiles roses, salue gracieusement la paleur triomphale de l'été qui s'avance calme sous l'or de son chapeau de paille, devant la sérénité bleue d'un ciel splendide. L'automne apporte ensuite la sumptuosité de ses rouges cuivrés, sonores comme des fanfares. Et l'hiver paraît enfin, dans des draperies de deuil. Mais sa vieillesse n'est pas isolée, car un être jeune (symbole des recommencements de la nature) l'accompagne doucement de son dévouement discret" (Fernand Khnopff).

Voici "Roma," une toile célèbre de la jeunesse de Smits, composition exécutée à Rome, actuellement en possession de Sa Majesté le Roi des Belges.

"Le Bonheur et le Malheur," d'après le poème de H. Heine. Le bonheur est une jeune fille qui passe un instant et s'enfuit en vous envoyant un baiser ; le malheur est une vieille femme qui s'installe à votre chevet et prend son tricot.

"Perdita," un petit bijou de raffinement coloriste, "une délicieuse figure féminine sur un petit panneau où l'on voit des blonds carminés, délicieux comme une soyeuse relique vénitienne, et des noirs aux profondeurs dorées, tels qu'en offrent les plus riches laques du Japon."

En voila assez pour vous donner l'envie de connaître l'œuvre d'Eugène Smits, ce Smits exquis qui fut l'intime ami de Ricard, de Jongkind, de notre grand sculpteur Paul de Vigne, d'Octave Pirmez, un pensif homme de lettres dont notre littérature s'honore.

J'insiste un peu sur cette personnalité d'exception d'abord parce que je l'aime, et c'est une excuse peut-être suffisante, et aussi parce qu'elle est encore inconnue à l'étranger et que je me sens en quelque sorte le précurseur de sa prochaine et inévitable gloire en lui rendant hommage avant que ce soit une opinion banale, consacrée par cette admiration toute faite qui ne voit plus, ne discute plus, demeure convaincue sur le dire de gens autorisés.

Vous n'avez pas pu constater ce que ces œuvres doivent au charme de leur couleur rare et personnelle, montrent de mesure et d'équilibre. La grâce des formes, l'eurythmie des attitudes, leur confèrent un attrait séducteur.

Comme l'a finement discerné Camille Lemonnier, "la peinture d'Eugène Smits éveille un goût de volupté langoureuse et noble. Il suggère le songe, la méditation, le désir, les regrets et l'amour . . . C'est le rêve de la vie qu'elle exprime dans des harmonies douces et ardentes comme des cuivres lointains. Les œuvres de Smits tiennent d'une sorte d'état d'âme silencieux et nostalgique."

Cela est justement pensé.

Si nous considérons quelqu'une de ces belles œuvres de Smits qui "par un côté touchent au

rêve,"* un profil de femme rousse, un coin de paysage sous un ciel bleu, une épaule nacrée au bord d'un corsage rose, la gaze noire d'une écharpe sur la pâleur d'un front, nous retrouvons dans notre propre passé, avec quelle émotion attendrie, un parfum qui fleure notre jeunesse, nos beaux espoirs que la vie devait decevoir, des apparitions fugitives qui firent battre notre cœur dans la sérénité ancienne des soirs d'été, des paysages entrevus au cours des prestigieux voyages, et, d'un mot, tous les mirages du passé aboli dont la mélancolie du présent est faite.

Je vous parlerai très brièvement de Madou, peintre de genre spirituel, un peu bourgeois, qui a laissé des ouvrages très fins dans lesquels se retrouve la verve d'un Teniers ou d'un Ostade; de Florent Willems, qui pasticha—un peu trop à mon gré—Terborgh ou Metsu, mais que la vogue a adopté longtemps; Jean Portaels, parce qu'il fut principalement un éducateur, un chef d'atelier, le continuateur de la tradition de Navez et de son maître David. Un grand nombre des hommes marquants de notre école doit quelque chose aux enseignements de Jean Portaels. C'était un professeur respectueux du tempérament et des dispositions de ses disciples. Il n'a pas coulé dans un moule unique leur inspiration et leur technique. Des peintres et des sculpteurs extrêmement différents entre eux se formèrent sous sa direction clairvoyante.

L'un des plus curieux fut Édouard Agneessens, qui mourut jeune et n'a pas laissé beaucoup d'œuvres. Ce fut un peintre sans grande imagination; il n'a guère traité que des figures isolées ou des portraits. Mais chacun de ses tableaux est un morceau de peinture d'une rare et personnelle saveur et qui durera.

Malgré mon désir d'éviter les énumérations et les notices et de m'en tenir à des aperçus généraux, il est difficile d'omettre les noms et les œuvres des hommes qui ont apporté une vision à eux et renouvelé des aspects de notre peinture.

Les images que vous venez de voir et les commentaires que vous avez écoutés vous ont fait apercevoir, je pense, quelque chose de l'évolution de la peinture pendant un demi-siècle chez nous, depuis le classicisme du début jusqu'au naturalisme discret des plus jeunes.

Le tempérament national a réagi contre les influences du dehors, il se les est assimilées en les adaptant à sa nature, en les transformant, en les rendant méconnaissables, ou bien il les a éliminées. Sans doute dans un pays au territoire exigu situé comme le nôtre au confluent de races et de civilisations diverses ces influences du dehors ont toujours été perceptibles. Nos artistes sont toujours attentifs à ce qui se fait à l'étranger, en France principalement. Il n'est par douteux que Courbet d'abord, Jean François Millet et plus tard les impressionistes n'aient leur reflet dans certaines œuvres belges d'une certaine époque. Courbet de son côté à été pénétré d'influences belges. Il a beaucoup travaillé chez nous. Le succès de Manet a eu son contre-coup dans nos ateliers. On s'est mis alors à étudier Velasquez!

Tout cela, qui est perceptible dans les tableaux à figures et les portraits que vous venez de voir, ne l'est pas moins dans le paysage ou la nature-morte.

Notre école de paysage d'après 1830 débute par des "compositions" artificielles, péniblement élaborées. Elle arrive assez vite à l'observation pure et simple de la nature, à la simplicité. Notre petit pays offre des aspects charmants et très variés. C'est comme un raccourci, un résumé des aspects de diverses contrées. La plaine stérile de la Campine avec ses marais, ses bruyères, ses sables, ses sapinières est bien différente de la plaine des Flandres fertile et grasse. Le Brabant ondulé, le Hainaut hérissé de charbonnages, de hauts fourneaux, d'usines et de manufactures, montrent des paysages très caractéristiques.

Dans nos Ardennes c'est la colline, les fagnes, les hauts plateaux, en Condroz les vallons rocheux, les sentiers creux entre les haies fleuries. Le cours de la Meuse, sinueux, parfois encaissé, reflétant les forêts, les villages de ses rives, diffère complètement du cours de l'Escaut, large, étalé, blond. Nos villes anciennes et pittoresques, nos villages aux types si différents entre eux, comme les sites agrestes ont trouvé leurs interprètes. Et la côte maritime, les plaines liquides de la mer du Nord ont inspiré nos peintres.

Chacun mit au service de ses interprétations ses dons personnels et ses croyances, ses recherches et son acquis. Cela forme une pléiade compacte d'artistes qu'il est bien difficile de grouper et de caractériser.

Fourmois est l'un des plus anciens. On goûte son talent de dessinateur, son sens d'observateur et la solidité de sa touche, en même temps que son coloris sobre et puissant.

Alfred de Khnijff aima des sites plus simplifiés, des paysages plus amples et moins encombrés. Il les traita avec une discrète maîtrise.

* Eugène Smits, "Écrits sur l'art."

Hippolyte Boulenger fut l'un des plus significatifs parmi nos paysagistes. Il rejeta les traditions académiques et le souci des compositions élaborées pour se consacrer ingénuement à l'école du plein air. Il a laissé des pages amples et fortes, très hardies pour leur temps, avec des orages, des arcs en ciel, des coups de vent, un souci d'observation météorologique très prime-sautier et très prenant.

Autour de lui se groupèrent les paysages de l'école dite de Tervueren, assez nombreux, dont je ne puis à peine vous citer les noms, Theodore Baron, Joseph Coosemans, Jean Degreef. Boulenger peut-être doit-il quelque chose à Constable, votre grand maître anglais, qui, formé lui-même d'ailleurs par notre bon paysagiste flamand Siberecht, est très compris et admiré chez nous.

Louis Dubois fut un de nos beaux peintres du dix-neuvième siècle, considérable surtout par des dons de coloriste et d'exécutant. Il a touché tous les genres et excellé surtout dans ceux qui exigeaient précisément le judicieux emploi de ses facultés un peu restreintes, la nature-morte, le paysage. On ne peut le passer sous silence.

Nous avons eu deux marinistes tout à fait éminents : Louis Artan, qui fut le peintre ému de la Mer du Nord, coloriste délicieux, capable de rendre tout le fugace et tout le mouvant de la vague et du nuage; et Jean Pierre Clays, qui peignit plutôt les bateaux que la mer, et trouva ses meilleures inspirations par de calmes journées, à l'estuaire de l'Escaut, parmi les chalands vernis sortis des canaux et déployant leurs voiles goudronnées.

Alfred Verwée est, à mon sens, un homme de tout premier plan parmi les peintres du dix-neuvième siècle. Il a étoffé de grands animaux les larges paysages de la Flandre, sous leurs cieux mouvementés. Sa couleur est une merveille de fraîcheur, de charme et d'harmonie. On lui a reproché parfois le dessin imprévu de ses chevaux ou de ses vaches. Mais depuis que les instantanés photographiques ont permis de décomposer les mouvements successifs des bêtes en marche, on a dû reconnaître que Verwée avait su apercevoir, discerner et rendre avec une merveilleuse précision des attitudes, fugitives sans doute, mais parfaitement justes. Un beau paysage de Verwée animé de bétail s'étend sous un ciel que la brise anime, il flatte les yeux par l'émail précieux la qualité incomparable de ses pâtes, il rafraîchit et réconforte comme l'air même de la terre natale.

La personnalité d'Alfred Verwée m'amène a vous présenter les peintres spécialistes de la peinture d'animaux : Verboeckhoven, Verlat, qui ne nous retiendront pas ; Joseph Stevens, qui a peint des chiens avec une incomparable maîtrise et composé des tableaux égaux aux plus appréciés d'entre ceux des meilleurs maîtres hollandais ou flamands du dix-septième siècle. Son frère Alfred lui écrivait un jour : "Moi je suis de mon temps, mais toi, Joseph, avec Fyt, Snyders et Jordaens, tu es de ta *race*. Ainsi tu es de tous les temps."

On ne saurait mieux dire, et c'est un jugement que la postérité ratifiera.

Jean Stobbaerts fut aussi un animalier de marque. Il a consacré ses pinceaux aux intérieurs d'étables, aux recoins vétustes des fermes et des logis populaires où les bêtes vivent pêle-mêle avec les gens.

C'est aussi un virtuose de la pâte, un remarquable exécutant qui sut faire de la robe tachetée d'une vache, de la croupe baie d'une jument ou des peaux rosées des petits cochons, des prodiges de peinture.

Une femme, Madame Henriette Ronner, hollandaise il est vrai d'origine, mais belge de cœur, et dont toute la carrière s'est déroulée à Bruxelles, fut l'interprète avertie et agile des chats, dont elle a peint les jeux ou les repos du bout d'une brosse désinvolte, avec de charmantes recherches de colorations.

Ce sont ces recherches de colorations, en même temps que la beauté du "morceau" d'exécution, qui fait tout le charme des "natures-mortes" et des tableaux de fleurs. La disposition native de nos artistes pour les harmonies de couleurs toujours renouvelés leur a permis d'exceller dans ces genres. Presque tous en ont essayé. Les "intérieurs" d'Henri de Braekeleer sont souvent des "natures-mortes." Alfred Verhaeren a continué de creuser ce sillon avec une brillante et savoureuse virtuosité. Mlle Alice Ronner, de son côté, y réussit à merveille, avec des dons très différents.

En parlant de ces artistes qui sont maintenant en pleine production je sors peut-être un peu des limites de mon sujet ét j'aborde un terrain glissant et dangereux.

Mais puisque ces peintres étaient déjà notoires, représentés dans les musées et les collections avant 1900 je continue à m'aventurer parmi eux.

Notre école de paysage comptait en ce moment un grand nombre d'artistes très personnels.

Je citerai d'une part Adrien Joseph Heymans, et Émile Claus, d'autre part Franz Courtens, et je mettrai à part Albert Baertsoen.

Heymans et Claus, avec des dons très différents et dans des pays qui ne se ressemblent pas. l'un en Campine, l'autre en Flandre, sont des peintres de la lumière, de la vibration lumineuse. Ils sont arrivés tous les deux à la plus exacte notation des couleurs sous le rayonnement diurne ou nocturne, et par leur sincérité et leur amour de la nature ils ont atteint une poésie très éloquente.

Courtens, au contraire, a aimé les matérialités, la substance des choses. Il a peint des paysages opulents et lourds, d'une indéniable puissance. Victor Gilsoul peut lui être apparenté en quelque façon.

Albert Baertsoen fut le premier à apercevoir la beauté de certains sites de nos vieilles villes endormies. Il a su se garder des *jolis coins*, trop jolis, qui séduisent le touriste superficiel, la demoiselle aquarelliste amateur, et le photographe pour cartes postales !

Il a planté son chevalet devant des choses que personne n'avait regardées encore, et il en a fait sentir tout le charme intense et recueilli.

Voici un tableau qui appartient au musée d'Anvers. Je regrette que vous ne puissiez apercevoir la modulation infiniment subtile des valeurs, la rareté distinguée de l'harmonie, tout ce qu'un œil de peintre fervent et fin a découvert dans cette petite place sans architecture.

Baertsoen a fait école. Je citerai près de lui Opsomer, Viérin, et je tairai beaucoup de noms afin de n'être pas fastidieux.

Le temps s'écoule, et je suis effrayé du nombre de personnalités très curieuses que compte en ce moment notre école et dont je n'ai rien dit ou trop peu parlé encore.

Xavier Mellery, peintre de la vie des choses et créateur de symboles plastiques, mériterait une étude.

Fernand Khnopff, maître de toutes les recherches, de tous les raffinements, mystérieux, et même parfois mystificateur, vous est heureusement connu. Vous avez apprecié son dessin élégant, la delicatesse de ses colorations, la richesse de son imagination dans les détails, la perfection de sa technique.

Mais nous avons James Ensor, à qui le grand poète belge Émile Verhaeren a consacré une monographie copieuse et que je sens trop complexe et inquiétant pour oser l'exécuter en cinq . . . phrases.

Et Alexandre Struys, qui a des œuvres dans tous les musées.

Et Théo Van Rysselberghe, portraitiste et paysagiste tout à fait moderne, féru des formules récentes, artiste éminent que Paris et la société cosmopolite un peu d'avant garde ont adopté.

Eugène Laermans, sourd et muet de naissance, interprète un peu gauche, un peu sommaire, un peu brutal parfois, mais toujours éloquent quand il nous montre la misère des humbles. Ses œuvres sont rehaussées par l'attrait d'un coloris rare et original, et un certain air d'être inspirées par notre grand Pierre Breughel. Armand Rassenfosse, Auguste Donnay, sont les peintres de la femme, et du terroir wallon, Charles Mertens et Émile Vloors sont parmi les "*encore jeunes maîtres*," des notoriétés de bon aloi de la ville d'Anvers.

Oleffe eut des débuts éclatants, et pareillement Henri Thomas. En vérité, ils sont trop ! Je devrais vous parler aussi du groupe des peintres idéalistes spécialistes de peinture monumentale.

Jean Delville, qui est connu ici puisqu'il fut professeur à Glasgow, Montald, Fabry, Ciamberlani. Combien je passe de noms et combien parmi les morts eussent dû être cités.

Félicien Rops, inquiétant, pervers, dessinateur merveilleusement incisif.

Théodore Verstraeten, qu'une exposition d'ensemble posthume, à Anvers a mis fort en relief.

Isidore Verheyden, auteur du portrait de Constantin Meunier, et Henri Evenepoel, un élève excellent de Gustave Moreau, fauché à vingt-huit ans, et dont beaucoup de musées belges et étrangers (Paris, Vienne, etc.) se sont disputé les toiles — espérance déçue sur laquelle je m'arrête avec tristesse et conclus.

Je vous ai montré, mesdames et messieurs, beaucoup d'images et commenté sommairement beaucoup de personnalités de peintres. Mais j'ai un peu menti à mon titre, et je n'ai pas eu le temps—ni le talent—de vous montrer une évolution, un développement normal, se transformant peu à peu sous des influences successives, vers le progrès, ou vers ce que nous croyons un idéal artistique. J'ai laissé à ces images sur l'écran et aussi à votre imagination le pouvoir des déductions et des vues générales, des vues d'ensemble. Je vous demande seulement d'acquiescer à ma constatation que notre école belge au dix-neuvième siècle fut, et est encore maintenant, très touffue et riche en talents originaux, nombreux et variés. Peut-être peut-on apercevoir chez certains de nos peintres une certaine maladresse, une certaine inaptitude à tirer parti d'un réel talent, de beaux dons, d'indiscutables qualités plastiques. On voudrait parfois chez eux plus de maturité d'esprit, plus

de réflexion, l'indication d'une mentalité cultivée capable d'extérioriser des conceptions moins matérielles. Mais cela est une lacune inhérente à la plupart des écoles et spécialement à celles qui groupent des hommes goûtant, par tempérament, la sensualité de la vision, la beauté extérieure des choses, et qui s'épuisent à la rendre dans son éclat éphémère.

Cet éclat des choses belles, des surfaces sur lesquelles jouent les lumières et les ombres, n'est-il pas, après tout, le domaine essentiel des peintres ? En dehors de cela, pour eux, tout le reste n'est-il pas "littérature" ?

The Chairman (Lord Sanderson, G.C.B., K.C.M.G.) said he was sure all present would wish that he should express to M. Lambotte their grateful thanks for the very interesting lecture he had given, which had been accompanied by a remarkable series of illustrations. M. Lambotte's enforced exile had been the Society's opportunity, but he was sure all the members hoped that it would not be long before the lecturer resumed his sway at Brussels, where they might have the opportunity of seeing in their real colouring in the museums of the country some of the beautiful pictures which had been described There were two ways, in his experience, of looking at sights of different kinds in foreign countries. The first was to read a guide-book beforehand, and then go and look at them, which was rather a severe method. The second was to go and look at them, and come back and read the guide-book and discover what they had not seen, which was rather a disappointing method. Those who had listened to the lecture would be provided with a general knowledge of what they ought to go and look at.

The resolution of thanks was carried, and the meeting terminated.

THE FLOWER TRADE BETWEEN FRANCE AND ITALY.

Until 1908, the Italian wholesale exporters of flowers were amongst the best customers of the growers in France. The conditions which now prevail in this trade have undergone considerable change during the last five or six years. The cultivation of flowers on the Ligurian coast has increased to such an extent that the export firms in Italy are now able to obtain their supply of flowers from the home markets.

Formerly only the commonest kinds of flowers were cultivated in Italy, so that it was necessary to import the more choice blooms, such as the stove-grown roses and carnations, from France to the value of upwards of 1½ million francs (£60,000) every year. This did not include the value of the consignments sent direct by the growers to the retail florists in the principal towns in Italy. On the other hand, large quantities of rose trees, carnations, and other plants were sent to France by the Italian nurserymen. In 1911 consignments of cut flowers from Italy amounted to 804 tons, half of which were roses and carnations and the remainder stocks, violets, anthemis, etc.

This cross-current of exchange may be accounted for by the difference in the flowering seasons of the two countries, and competition is not to be feared except in February, for the reason that those grown in the open in Italy and sheltered only by matting do not bloom so early as the French plants.

In France the first flowering season for roses grown in the open air finishes in December, whilst those of Italy, which are remarkable for the beauty of their colouring and length of stalk, are available in January and February, before those grown under glass on the French side are ready for market.

If the open-air carnations of Italy are less choice than those grown under glass in the neighbouring country, they are, on the other hand, more rigid and travel better.

This mutual exchange gives employment to about a hundred or more small dealers in France, who cross the frontier daily with their produce, which they sell at Ventimille, Ospedaletti, or San Remo. They return to their homes in the evening laden with other flowers purchased at Ventimille, which are sold the following morning at the markets of Nice, Antibes, Cannes, and even Hyères.

During the season large quantities of roses for the distilleries at Grasse are brought daily from Italy. They are sent in sacks, which now must be sealed and accompanied by a certificate signed by a Government official to the effect that they came from a district unaffected by *disapsis pentagona*. Considering the importance of this trade, it is not surprising that a great outcry was raised on both sides of the frontier by those interested at the restrictions placed by the Government on the introduction of Italian flowers, many of which now have been removed. Cut flowers are now permitted to enter France from November 1st to May 1st, after which they must be accompanied by a certificate from the competent authorities appointed by the Italian Government as to their freedom from disease.

EXTERMINATION OF FLIES AND MOSQUITOES.

A French journal, *L'Agriculture Nouvelle*, gives an account of some experiments made by M. Lang, a veterinary surgeon, in the French colonial service at Noumea (New Caledonia), for the extermination of a species of horse-fly which infested the animals under his charge. This insect, which appears to be very tenacious of life and difficult to kill, is only driven away for a short time by applications of cocoa-nut oil, oil of juniper

berries and petroleum, and quickly returns to resume its attacks. Wounds or sores are very difficult to heal on this account, as the insect is a carrier of contagion.

The remedy, which is simple and is said to be effective, consists merely in anointing those parts of the body of the animal infested with these pests with cod-liver oil. The flies are killed immediately by contact with the oil. No caustic effect to the skin of the animal is produced by this oil as is the case with other fish oils.

The application of cod-liver oil is equally efficacious for the extermination of the common house-fly as well as the mosquito. Ticks, which infest dogs, sheep, and other animals, can be readily destroyed by an application of cod-liver oil. The effect of these applications lasts from ten to eighteen hours.

Spread on the surface of pools of water this oil has the effect of killing immediately the larva of the mosquito.

NEW USES FOR BY-PRODUCTS OF HENEQUEN IN MEXICO.

Several new processes have been recently discovered for using by-products of the henequen plant, which will favourably affect the fibre industry of Mexico, particularly in the States of Yucatan and Campeche. For many years methods have been sought to utilise the waste from henequen leaves after extraction of the fibre, but without much success, but recently certain experiments made with the object of discovering a perfect machine for simplifying labour in extracting fibre from the leaves, and for utilising the by-products, have proved successful. A machine has now been invented which is intended to reduce the labour in feeding the leaves into decorticating machines. One man feeds the leaves directly to the decorticators, and takes the place of six to ten labourers previously necessary. It is anticipated that a large number of similar machines will be manufactured for sale to the many henequen plantations in Mexico. In addition, experiments are being made with machinery for manufacturing paper from henequen-plant stumps, which have heretofore not been utilised. The experiments so far made have been successful. Henequen plants, after a number of years, fail to produce leaves of such quality that they can be utilised for fibre, according to the United States Consul at Progress, Yucatan. The stumps are left on the ground and destroyed. This is done at considerable expense, and any method by which they can be used adds to the farmers' profits. The new process accomplishes this, and it is proposed to erect paper factories on henequen plantations for utilising these stumps if the process proves as satisfactory as seems probable. It is said that not only can the stumps be utilised, but also the waste from the leaves known as "bagazo," enormous quantities of which are left to rot outside all henequen fibre factories. The paper, it is stated, can be produced from the stumps and "bagazo" in commercially satisfactory quantities, and sold on local markets at one-quarter to one-third the price of any other paper on the market. It is not probable that this paper will be exported to any great extent, as there is a sufficient market in Mexico for the quality which will be produced, but if the manufacture is carried out as extensively as anticipated it must have a large effect on the paper market in Mexico. The paper, which has been manufactured in experimental quantities, consists of brown, heavy quality paper, a dull buff colour, partially-bleached thinner paper, and a completely-bleached cream paper of excellent quality, similar to other wood-fibre papers, but of exceptional strength. It is stated that there will probably be a large demand for the machines referred to above. If the plan proves as successful as it is hoped, a larger income will be obtained by the henequen planters of Yucatan, especially as it contemplates the use of materials which have heretofore not only been without commercial value, but whose destruction has been a continual annual expense to the planters. In addition to the paper produced, alcohol is also produced from the stumps and "bagazo" by the same process.

THE PANAMA CANAL FROM AN ITALIAN VIEW POINT.

The probable effects on the world's trade, and on Italian commerce in particular, by the opening of the Panama Canal, appear to have been very carefully examined by Dr. Giovanni Tempini in "Il Canale di Panama," published by L' Instituto Italiano per l' espansione Commerciale e Coloniale of Venice. Commencing with a brief history of the undertaking, the author ascribes its earliest conception to Angelo Saavedra, who, in 1520, first proposed the cutting of an inter-oceanic waterway across the Isthmus of Darien. The *raison d'être* of the canal and its advantages to the United States first and foremost are too well known to English readers to need repetition here. England, amongst the nations of Europe, will certainly be the chief gainer by its construction, whilst France, Germany, Belgium, and Holland may benefit in a lesser degree. With regard to Italy, the author takes a decidedly pessimistic view. The shortening of the distance by sea between New York and Yokohama will enable the Japanese to flood the markets of the Eastern States with raw and manufactured silk to the detriment of Italian industry, by which they are at present supplied. Californian wines, canned goods, and other produce of the Pacific Coast will rapidly displace Italian in the markets of North America. The author urges his fellow-countrymen to cultivate commercial relations with other nations of the Latin race in the South American continent, and more especially with Peru and Chili. The new route to these countries on the Pacific Coast will no doubt attract Italian emigration, and open up fresh markets for goods of every description.

KAPOK CULTIVATION IN CEYLON.

Recent inquiries from Europe and the United States seem to indicate that a considerable commercial interest has developed in the production and uses of kapok. The kapok is a tropical tree found largely in both the East and West Indies. Another species, not so tall, is found in Mexico. In the East Indies the tree is more largely cultivated as a crop in Java and in the Philippines. Under American rule in the Philippine Islands, according to the American Consul at Colombo, the cultivation of kapok has been scientifically studied and developed to a certain extent along modern agricultural lines. In Java, however, from which place considerable quantities are exported to Europe, kapok is cultivated only as a secondary crop, and the methods employed in its production are primitive. In Ceylon, kapok could hardly be described as a seriously cultivated crop at all, though it is one of the easily-grown products of the island. It is generally planted along the roadside and around the boundaries of gardens, as a sort of extra crop from what would otherwise be waste land. About the environs of Colombo the tree is largely grown as a border tree for canals and earthworks, where erosion might otherwise destroy the banks. It has a wide distribution, however, over the low country, and up to an altitude of 2,000 ft. The kapok is a fairly tall, gaunt, deciduous tree with a straight trunk, and its many branches jutting out in groups of three at right angles to the bole, make it easily recognisable. The peculiar odour of its flowers has a strong attraction for bats, and consequently flowers are destroyed by thousands which would otherwise produce pods of the silky floss or kapok of commerce. One of the drawbacks against attempting to cultivate the tree in Ceylon with the expectation of any large profits is the presence of these bats in immense numbers. The principal obstacles so far encountered in its cultivation, however, are the cost of labour, as compared with the price paid for the product, and the difficulty of gathering the crop. Most of the pods containing the floss grow on the end of the branches, and it is not easy to induce the labourer to take the risk of gathering them among these slender branches at a considerable height from the ground. The use of step-ladders as a means of gathering crops has never been introduced in Ceylon, and it is hardly probable that for such a crop as kapok alone they could be employed with advantage. Moreover, the business of gathering the ripened pods is a rather slow one, as only the most careful and experienced coolies can tell when they are ready for harvesting. Before ripening, the kapok pods are of a light green colour and smooth, but at the right time they become wrinkled and brownish. If left even for a few days longer the floss often loses its lustre and soft quality, and is of little value. Most of the kapok now being exported from Ceylon comes from the Matale district to the north of Kandy. In this district the tree does not grow so tall, and with low outstanding branches is more like a shrub; it is, therefore, easier to gather the pods. The pods are picked by hand and cured by being allowed to dry thoroughly in thatched sheds at the homes of the villagers. They are then broken, and the "cotton" or floss is roughly hand-cleaned by coolie women. It is then packed in bales and sent to Colombo, where the seeds are removed by special machines.

VITICULTURE IN PERU.

Before its introduction into Peru the vine was imported into South America, at the beginning of the sixteenth century, by Francesco Caravantes, and according to M. Molinatti, an Italian viticultural expert, grapes were eaten at Cuzco, Peru, for the first time in 1555. At the present day the varieties of vine stocks existing in Peru are as follows: The most common is the Quebranta, then come the Negra and the Moyar. Less known are the Albilla and the Rosada, as well as the aromatic vines, Italia and Moscatel. After these—but at a long distance—are classed the Française, and last of all the Barbera, Alicante-Bouchez, Grand Noir de la Calmatte and Teinturier. In the Department of Moquegua are found the Sémillon and Sauvignon, and in the Department of Chincha, the Isabella. The three first varieties, which are local vines probably derived from the original vines imported into Peru, are the most productive. The others have a less prolific yield, and come from various vine-growing countries. The most productive vine of all is the Quebranta, which yields a wine which is, however, somewhat insipid. This vine suffers neither from the oidium nor the peronospora, pests which are very prevalent in Peruvian vineyards. Quebranta, Negra, Moyar and Moscatel yield black grapes, but the wines produced from them are not particularly good. These grapes, however, are largely cultivated for brandy making. The Albilla and Italia are very susceptible to attacks of the oidium and peronospora. The Albilla is sometimes mistaken for the Folle Blanche de la Charente, but the species are quite distinct. The Italia is one of the most highly appreciated vines in Peru. The grapes from this vine are held in high repute, and much business is done in them as fruit for the table. The Rosada has no particular value from a commercial point of view. The Moyar is used to fortify other wines. Wine from La Française has a distinct taste, it is said, of pitch. It is used for blending with other wines. The other vines do not call for any special mention, but they are all used in the production of wine which is consumed in Peru.

ABYSSINIA AND ITS TRADE.

The commercial future of Abyssinia, judging from the last report on the trade, is full of promise, for the country is naturally very rich and bears a large population with an aptitude for trade. This trade is as yet in its infancy, large tracts being up

till now practically unexploited. Development is, however, rapidly proceeding. Generally speaking, the southern half of Abyssinia is richer than the northern, and the districts in which trade is most highly developed are those of Jimma and Kaffa in the south west and of Harrar in the east. Adis Ababa, the seat of the central government, has a population of from 40,000 to 50,000, which fluctuates according to the number of troops which happen to be quartered in the town; the foreign population, viz, merchants, contractors, artisans, etc., numbers about 1,200, and consists largely of Indians, Greeks, and Arabs. Legations are maintained by the United Kingdom, France, Italy, Russia, and Germany, and a Consulate-General by the United States. Among the chief business offices are two telegraph offices, a postal service, a telephone system, and a custom house. Adis Ababa will be the terminus of the Franco-Ethiopian Railway. There are two hotels with comfortable accommodation, at which rates *en pension* are £6 and £5 per month. There is a large market place, which presents a busy appearance, and where on Saturday (the market day) a great concourse of people assembles from the surrounding country.

The Government has recently erected an electric power-station on the River Akaki, some 18 miles from Adis Ababa. The current is already laid on to the Government cartridge factory, a mile outside the town, and there is a project on foot for the electric lighting of the town. Land in and around the town is privately owned and very costly, as are also building materials and fuel; but it is anticipated that when the railway from Jibuti to the capital is completed, timber required for building purposes will probably be imported. There are forests of good timber that exist in various parts of the country, but these cannot be exploited owing to the difficulties of transport.

Harrar, which lies 6,000 feet above the sea, contains some 40,000 to 50,000 inhabitants, and is the centre of a rich coffee-producing district. A Chamber of Commerce was formed by the merchants at Harrar in 1914. The town has lost a good deal of its importance as a collecting centre owing to produce which formerly came thither now being taken direct to the stations on the Franco-Ethiopian Railway, this being, of course, the main avenue along which trade passes. At the end of 1913 goods were being received for transport as far as the Hawash River, 227 kilometres from the capital, which was expected to be reached about the present time (1915). The figures of the goods conveyed by the railway show a steady increase during the past five years, and an abnormal increase in the imports in 1913.

The value of the trade between Abyssinia and the British Somaliland ports amounts to about £61,700, the principal articles of export being skins, hides, glue, coffee and grain. It was inevitable that the construction of a railway from the port of Jibuti into the interior should adversely affect the prosperity of the adjacent port of Zeyla. From 1901, when the railway was partially opened for traffic, the value of the Zeyla trade began to diminish steadily till 1907-8; but since the latter year there has been a slow but steady revival.

Gondar, once the capital of Abyssinia, is now merely a collection of squalid huts clustered round the ruins of its former greatness. There are considerable possibilities, however, for trade in this corner of Abyssinia. The Italian Government has maintained a commercial agent and a doctor at Gondar for the last four years, while a British Consul for N.W. Abyssinia is also stationed there. Another convenient centre for trade is Gore, in the west, the headquarters of the British Consul for Western Abyssinia, and here the Bank of Abyssinia and several business firms have opened branches.

In the Adis Ababa export trade hides and skins are the largest item, 4,105 metric tons being exported by the railway in 1913. In normal times these are mostly exported to Hamburg, Havre, Marseilles, and Salonica, whence a considerable quantity find their way to the United States. Coffee is of two sorts—the Harrari, a fine yellow berry, which is mostly sent to Aden, where it is mixed with Mocha coffee and sold as "long-berry Mocha" in the United Kingdom and America. The other sort is Abyssinian coffee, the most important product of the south-west, where enormous forests of it grow wild and are hardly as yet exploited. There being a sufficient demand in Khartoum to absorb all that comes on to the market, practically the whole of this coffee finds its way out through Gambela on the River Baro, a tributary of the White Nile, by which way it reaches its destination by water. Other products include wax, ivory, rubber, civet and gold. Ivory and rubber are Government monopolies. Gold is washed by the natives in many of the rivers, and though so far the spasmodic efforts of prospectors have not met with much success, it is more than probable that some day the discovery of gold in sufficient quantities to make dredging operations pay will be made. At present the annual export of gold amounts to about £50,000; the total production is, doubtless, considerably more

ARTS AND CRAFTS.

The Exhibition at Goldsmiths' Hall.—**The exhibition of German and Austrian articles typifying successful design, held under the auspices of the Board of Trade at Goldsmiths' Hall, though it was only open for three days, aroused a good deal of comment, both favourable and unfavourable. That was due in a measure to the exhibition itself, but also in part to the literature circulated, both by the Board and by some half-dozen art workers, who advocate the foundation of a Design and Industries' Association, and who, by their whole-hearted enthusiasm for the work shown, did much to convince hesitating visitors of its excellence. With regard to the works exhibited, while there is**

no doubt whatever about their interest, there seems some danger that their significance and importance may be over-estimated in certain quarters. In the first place, it has to be remembered that the work shown at Goldsmiths' Hall, though it adequately represents a certain advanced type of German and Austrian manufacture, is by no means typical of German production as a whole, some of which—it would not be altogether unfair to say, much of which—is at least as dull and lifeless as anything produced in this country. Again, the exhibits represent what has found its way, for one reason or another, into Great Britain. There is no record of how the various objects have sold, or whether they can lay any claim to have been a commercial success. It looks, upon the face of it, as though the printed cottons and linens (all of them apparently Austrian, by the way) which made such a striking show at the exhibition, while they would undoubtedly attract attention in a shop window and be a useful extra line to help to introduce other goods, would only command a very limited sale. They were well worth study, for though some of them were delirious enough to justify the remark of a depressed manufacturer, who declared that if he produced stuff like that he would soon be ruined, there was a certain freshness about them, a clever recognition of the possibilities of black and of outline, a daring and occasionally happy use of bright colour, which made them very full of life It is worth recalling that the German cotton prints exhibited by the Board of Trade at Cheapside some weeks ago were dull and hackneyed in the extreme. This, combined with the fact that the very few wall-paper designs shown at Goldsmiths' Hall were not peculiarly fresh or original, leads one to wonder whether the statement in the official pamphlet that "a large section of the public is sympathetic towards original efforts, and hitherto their demand has been largely met by foreign productions. An instance of this is that half the wall-paper designs issued by the principal wall-paper manufacturers in this country are believed to have been designed abroad," is not rather misleading. It is always difficult to get at facts of this kind; but undoubtedly a considerable proportion of the foreign designs brought over here are purchased, not because they are original, but for a variety of other reasons. There are certain styles, for instance, demanded by the public which a Frenchman can handle successfully and an Englishman cannot. (There is, of course, no denying that many of the foreign patterns bought are French and not German.) There are certain technical conditions to which foreign designers are sometimes more ready to conform than British artists. Again, some of our best English paper-stainers procure their designs mainly, if not entirely, from native sources. In the face of all this, it is by no means safe to assume, without further proof than seems to be forthcoming, that the bulk of foreign patterns used in this country represent the newest or the best type of work, though some of them possibly do. Nevertheless in various simpler branches of design and workmanship there is abundant evidence that the German work is very much alive. People who covered their floors with linoleum chosen from the small samples shown would probably be more than a little disappointed with its effect when it was laid, but purchasers of smaller articles would have no cause to repent of their bargain. The collection of cardboard and tin boxes for cigarettes and the like showed much more cleverness than work of the same type designed over here, and the posters were a striking proof of what excellent cheap lithographic work is being done in Germany. Most of our best posters are designed for the three-colour process, but the German examples shown the other day prove beyond all gainsaying what good results can be achieved in this direction by a scientific use of lithography. Of the printing and general get-up of some of the catalogues and cheap books it would be difficult to speak too highly. The replicas of peasant pottery are on the whole better made than our own work of this kind, but the texture of the glaze of some of the "leadless glaze" ware was unpleasant in the extreme, whilst the more or less artistic cheap crockery probably appeals rather to those who see it for the first time than to the people who have met its like in numerous foreign hotels and restaurants. Further, the official note on ceramics, while it shows that its writer is well up in modern German production, makes rather scant acknowledgment of all that is being done over here. It is true that we are producing quantities of dull and inartistic designs and objects, but we are also doing some good and original work. Moreover there is evidence in the pottery as in other crafts of Germany's talent for borrowing. It looks as though her success may be in no small measure due to the inadequacy of the international arrangements for copyrighting designs. It is, to say the least of it, hard when a good design for which a fair price has been paid has to compete in the open market with a rather inferior rendering of itself sold at a much lower figure. There is room, plenty of it, for improvement in our design, but we shall hardly arrive at it by setting up German cleverness, which has succeeded partly through its imitation of us, partly through its not entirely commendable business methods, as a standard worthy of unbounded admiration. It is easy to praise the work shown at Goldsmiths' Hall and to say, with its admirers, that it represents a national ideal, but have we adequate proof that it does so? Besides, it has to be borne in mind that the national ideals of Germany, Austria and Hungary are not, to say the least of it, identical in the artistic any more than in the political sphere.

Design and Industry.—The plea for the foundation of a Design and Industries' Association put forward by the unofficial committee responsible for

the Memorial as to Industrial Design, and circulated at the Goldsmiths' Hall exhibition, comes at a good moment, and its object, the association of manufacturers, designers, distributors and others interested in order to encourage the production under ordinary commercial conditions of attractive and carefully-designed modern work, is wholly commendable. It is only too true, as the writers of "Design and Industry" urge, that hitherto "the designer and the manufacturer have...largely remained in separate compartments, and that the purchasing public had yet a third point of view." But an amelioration of that state of affairs can only come about when each of the three parties cries *peccavi*. No amount of pointing out their obvious duties to the other sinners by any one of the offenders will bring about the desired result, since the existing muddle is the outcome of faults on all sides, and not of one party alone. The authors of this appeal are artists, they naturally see that the manufacturers have been at fault. They rightly point to our Arts and Crafts movement as the fount and origin of the German advance, and they state the benefits which would accrue if the designer and the manufacturer came into touch by the simple process of "the employment of the best available talent." There is, however, one point which they seem to leave out of account. The Arts and Crafts movement in this country began as a movement more or less on the lines of the proposed association. It included within its ranks not only craftsmen, but "paper designers" and even manufacturers. That it has in some measure failed to attain the larger ends to which it originally aspired is due, no doubt, partly to the manufacturers and the general public, but also in no small measure to the younger generation of artist-craftsmen themselves who have been so carried away by the glamour of making something with their own hands that they have had little but contempt to offer to manufacture and everything connected with it. If they have repented of this attitude, or if a still younger generation is arising ready to give of its best to help forward the artistic interests of production on a large scale, not from a lofty and far distant height, but as loyal co-operators with the manufacturers, convinced that in so doing they are really furthering the highest claims of art, there is good hope that things may improve.

CORRESPONDENCE.

CUTCH IN MALAYA.

I am desired by the court to inform you that their attention has been drawn to an article which appeared in the issue of your *Journal* dated March 26th, on the above subject.

In paragraph two of the article particulars are given of the quantity and value of the product imported into the colony during the year 1913. It is noted that no mention is made of cutch manufactured in North Borneo, but it may interest you to know that in that year the product to the value of £23,423 was exported from the territory.

It has occurred to the court that you might care to supplement the article referred to by these figures.

HARINGTON G. FORBES, Secretary.

The British North Borneo Co.,
37, Threadneedle Street, London, E.C.
March 31st, 1915.

[The article in question was based on a report of the Malay States Information Agency, and the statistics only referred to the amount of cutch imported into the ports of the colony.—ED.]

OBITUARY.

LORD ROTHSCHILD, G.C.V.O.—The financial world has suffered a severe loss by the death of Lord Rothschild, which took place at his residence in Piccadilly on March 31st.

Nathan Mayer de Rothschild was born in 1840; he was educated privately and at Trinity College, Cambridge, and on leaving the University he entered the famous office in New Court, St. Swithin's Lane, which was directed by his father, Baron Lionel de Rothschild, with the assistance of his two brothers, Baron Mayer de Rothschild, and Sir Anthony, the President of the Jews' Free School.

The part played in British finance by the house of Rothschild is common knowledge. One of their greatest feats was to arrange the purchase by the British Government in 1875 of the 176,602 shares in the Suez Canal Company, owned by the Khedive Ismail. The transaction involved the enormous sum of nearly £4,000,000, but it was carried out with extraordinary ease and smoothness. The late Lord Rothschild also took an important share in reforming the finances in Egypt during the difficult period 1878-88, and the present condition of the country is due in no small measure to the services of his firm. He had also large interests in South America.

In 1865 Mr. Rothschild (as he then was) entered the House of Commons as member for Aylesbury—a seat which he occupied till 1885, when he was created a peer. He was naturally regarded in the House as the recognised authority on all financial matters. At first he was a follower of Mr. Gladstone, but he was unable to accept the Home Rule Bill, and he became a Unionist Free-Trader.

As is generally known, Lord Rothschild took a deep interest in the welfare of the Anglo-Jewish community, of which, like his father, he was considered the head. He was a most generous benefactor of all Anglo-Jewish institutions, his private benefactions and those of his firm being alike munificent.

Nor was his generosity by any means limited to Anglo-Jewish charities. His purse was always open to any deserving cause. Among the last

tasks which he undertook was the chairmanship of the council of the British Red Cross Society, to which over £1,000,000 has been contributed since the outbreak of the war.

His services to the agricultural industry should not remain unmentioned. In the breeding of pure-bred stock, Tring Park made a world-wide reputation. In horses, cattle, sheep, as well as poultry and dairying, it was regarded as an example to all, and in each of these sections Lord Rothschild himself took the warmest interest.

Lord Rothschild became a member of the Royal Society of Arts in 1887. In 1901 he was elected on to the Council, on which he served as Vice-President till 1905.

NOTES ON BOOKS.

First Principles of Production. By J. Taylor Peddie, F.S.S. London: Longmans, Green & Co. 5s. net.

Of recent years, and especially of recent months, a very great deal has been talked and written about the connection between science and industry. The question is undoubtedly of the first importance to us as a nation, and the more it is discussed—provided, of course, that the discussion eventually leads to something practical—the better it will be for the prospects of our industrial prosperity. For this reason we may extend a welcome to Mr. Taylor Peddie's volume, which is perhaps the more interesting, as the author approaches the subject from the industrial point of view, whereas most of those who have hitherto taken part in the discussion have spoken from the scientific side. The book consists of a number of articles, the main object of which is "to open up a series of opportunities from the workman at the machine to the student at the university." Most of these are from Mr. Taylor Peddie's pen; but he also includes articles on "The Co-operation of Science and Industry," by Mr. S. Roy Illingworth; on "The Influence of Brain Power on History and Industry," by Sir Norman Lockyer; on "Steel Industry: Opportunities for Britain," by Dr. William Lorimer; and on "The Chemical Industries of Germany," by Professor Percy Frankland.

To Fellows of this Society, who have attended the meetings held here during the present session, or read the reports thereof in the *Journal*, there will not be very much that is fresh in what Mr. Taylor Peddie tells us of the respective conditions of industry in Britain and Germany. Possibly his most interesting article is that which deals with "Finance and Industry." Dr. W. R. Ormandy, in a paper read before the Society in December last, described the part which the German banks play in assisting industrial development. There can be little doubt that this attitude of the German financiers accounts as much as anything for the extraordinarily rapid growth of German industry, and it is to be hoped that in this respect our banks may learn to take a leaf out of the German book; but, as Mr. Taylor Peddie points out, this system could only be adopted in this country with reservations. "The policy of advancing loans on the strength of prospective orders to individuals who do not possess established businesses is very unsound for the reason that costs of production during the first three years of the life of a business cannot be gauged with any degree of accuracy, even assuming the efficiency of the management to be good. The works have to be first of all created, then the right kind of machinery and labour has to be obtained, skilful managers selected, and last, but not least, good managing directors must be secured. The whole organisation then has to carry out tests and experiments, and tune itself up to work cohesively and efficiently in production. As the cost of completing the organisation, therefore, cannot be gauged with any degree of accuracy, it will be seen that any bank advancing loans without security to establish a new industry is embarking upon business of a highly speculative nature." These words, no doubt, represent with sufficient accuracy the conservative attitude of the British banker; but if the British manufacturer is to be lashed—as he has been for the last twenty years—for his failure to encourage the co-operation of science and industry, why should the British banker go scot-free when he is committing the same offence?

We have heard a great deal about the organising and administrative ability of the Germans, and a corresponding amount about our own methods of "muddling through." This is natural enough in a people that is always ready to see its own faults, and the virtues of others; but there are among us a certain number who venture to doubt whether Germany is after all so wonderful in this respect. Professor W. J. Ashley, for instance, who certainly speaks with high authority here, said at a recent meeting of this Society: "I decline to take it [the German Beamtenthum] quite at its face value. It makes a proud and justifiable display of all its achievements, but I doubt if it can show anything quite so big as the way in which this country took up the colossal task, not only of sickness insurance, but also of unemployed insurance—which German administrators had been afraid to tackle and all in a single year."

Mr. Taylor Peddie appears to be of those who believe that we are far behind our enemies in the matter of organisation, and the chief remedy he proposes is "to see that a proper commercial and technical educational system is established in the universities, technical colleges, and secondary schools in Great Britain. We must establish a B.Sc. degree in Industry, and assist in the drafting of the curriculum."

There are, no doubt, many intricate problems to be studied in connection with industry, as a glance at the syllabuses of the lectures delivered at such a college as the London School of Economics will

show; but is it yet proved that the kind of course which would lead to a B.Sc. in Industry is the best to turn out organisers? In a paper which was read here in 1912, Mr. H. A. Roberts, Secretary to the University of Cambridge Appointments Board, mentioned that of a certain group of 50 Cambridge men employed in commerce by five or six great organisations, 19 graduated in classics, 5 in history, 5 in law, 1 in theology, 4 in modern languages, 8 in mathematics, 5 in engineering, and 8 in natural sciences. "The classical ability," he added, "shows up extremely well." And what educational system was responsible for Mr. Lloyd George's "discovery of the war"—the man who organised the transport of our army to France? Winchester and Oxford—perhaps the most unpractical system of acquiring useless knowledge that even this country can boast. The gigantic task mentioned by Professor Ashley of establishing both sickness and unemployment insurance was also almost entirely the work of men of similar training.

Whilst we are all one in the desire to do everything possible to improve the condition of British industry, there are at least two schools of thought as to the way in which it should be done Would the commercialising of the universities assist? We doubt it, and even if it did so, what would be the price? Important as industrial prosperity may be, it is not everything. Germany has staked almost all on securing it, and to achieve her end she has not hesitated to use in business methods similar to those which have made her name infamous in war. Is commercial prosperity worth having at the cost of one's good name? It is not suggested that the effect of studying political economy demoralises one's sense of honour; but if material success is made our chief criterion, there is a danger of losing sight of those higher ideals which have certainly raised us above the level of Teutonic culture, and which have found their principal home in the older unpractical universities.

GENERAL NOTES.

British Industries Fair.—As a complement to the series of Exchange Meetings which have been organised by the Board of Trade in the last few months, at which samples of German and Austrian goods have been exhibited with a view to finding British manufacturers prepared to make goods to compete with them, a display of samples of British goods in a number of the trades in connection with which the Exchange Meetings have been held is now being organised. This display is intended to reproduce the main features of the well-known Leipzig Fair. It will be held at the Royal Agricultural Hall, London, from May 10th to 21st, and will be styled "The British Industries Fair." Only British manufacturing firms will be permitted to exhibit. No exhibitor may exhibit articles other than those of his own manufacture and included in the following trades: Toy and games trade, earthenware and china trade, glass trade, fancy goods trade, cutlery trade, electro-plate trade, clock trade, jewellery and drapers' jewellery trades, including buttons, studs, push-buttons, pins and needles, stationery and printing trade. The Board of Trade will undertake, among other things, the preparation of a catalogue of exhibitors and the general decoration of the hall.

Mercantile Marine of the World.—The following figures, published lately in America, show the tonnage of the seven principal merchant navies of the world in order of their importance:—

	Gross Tonnage.
Great Britain	20,075,791
Germany	4,998,746
United States	3,489,736
Norway	2,475,324
France	2,246,504
Japan	1,700,062
Italy	1,571,761

From this it will be seen that the tonnage of the British merchant shipping is about four millions greater than that of the six other countries taken together. It should be noted that the figures for the United States include about one and a half millions of tonnage of shipping on the great American lakes, and should be deducted, in order to compare fairly with the other nations, and the United States would therefore occupy the fifth instead of the third place, coming between France and Japan in the above list.

"Pusa 12" Wheat.—The *Agricultural Journal of India* for January contains further information about "Pusa 12," the wheat that seems to have a great future before it, thanks to the scientific work done by Mr. A. Howard, Imperial Economic Botanist, and his wife as his personal assistant, and Mr. Leake. The environment experiments undertaken from 1909 onwards showed that all the Pusa varieties did well in Bihar, the United Provinces, and Central India; but one variety gave equally good results in the Punjab, United Provinces, South Bihar, and the Central Provinces. This was "Pusa 12," and it proved itself to be the best wheat for India as a whole, both as regards yield and quality. The cultivators themselves grew the variety from seed supplied to them; so the experiments were absolutely fair in different parts of the country. We are told that "Pusa 12" has another advantage in addition to its yielding power and quality, namely, its characteristic appearance in the field which distinguishes it at once from the country wheats. "The beardless ears are long, with shining red chaff, and the straw is quite different in tint from that of most Indian wheats. Its appearance in the field and the large elongated grain enable this variety to be instantly distinguished. In any scheme of seed distribution, which aims at replacing the existing wheats by a new kind, it is a great advantage if the improved variety can easily be recognised in the field and in

the market." The time appears to have come for the establishment of this improved grade of white wheat over a large area of the wheat-growing tracts in India, and the wheat must be brought to the notice of the Home millers in the form of one or two experimental shipments, so that they may have an opportunity of getting first-hand experience of its qualities and behaviour. Then will come an efficient organisation of the seed-supply so that all demands can be met. In Bihar the bulk of the seed raised in the seed-farms in the province is to be concentrated into a single circle; and in the United Provinces the central circle has been chosen for work, mainly on account of the local development of the co-operative credit movement and of the close working arrangements that exist between the societies and the Agricultural Department. By means of the societies an effort will be made to replace the existing wheats as far as possible by the new kind, and to supply the trade with as much surplus seed as can be obtained. At the earliest moment this will be secured for the first shipments to Europe. In the work of buying in the seed and in placing it on the markets in Europe to the best advantage the interest and assistance of Messrs. Ralli Brothers have been secured. Mr. A. E. Humphries, a former President of the Incorporated Association of British and Irish Millers, has promised to bring the matter before the Home millers and assist in the establishment of the new grade in England as soon as the first shipment has been collected.

HONG-KONG'S WIRELESS STATION. — Writing from Hong-Kong on the subject of the long-discussed wireless telegraph for Hong-Kong, which is at last to be carried out, the American Consul-General there says that the proposed radius of service has been enlarged to 500 to 700 miles per day and 1,800 miles or over by night under normal conditions, and the plant is expected to be in operation within five months. The inauguration of this service has some additional importance in view of the fact that the large wireless stations of the Chinese Government at Canton and Woosung, near Shanghai, are now working, and those at Foochow and Hankow will be completed by the time the Hong-Kong station is in working order. The service of the two Chinese stations now ready was commenced with the beginning of the year. They cover substantially the same radius as the Hong-Kong station, the plants thus being able to exchange messages with each other as with all ships in Chinese waters. A typhoon warning service is one of the first features adopted by the new system. All these coast stations are of the same construction. The oscillating power in the antennæ radiating the waves is 5 kilowatts (6·7 horse-power) with a current of 32–38 amperes. An official statement reports that the stations are fitted out with a 28-horse-power benzine motor, driving a dynamo and supplying the necessary current for charging an accumulator battery, from which the current is then taken for transmission to the transmitting machinery. A "converter" run by this battery will supply an alternating current of 500 cycles per second, which is stepped up to some 10-1,200 volts. The plant produces waves with lengths between 600 and 3,000 metres. The receivers of all the stations can pick up waves of all lengths between 300 and 4,000 metres. The stations are manned by a Chinese staff educated by foreign experts in the Pekin College of Communications. The Woosung station has been opened for day and night service, and the Canton station is open from 8 a.m. to 10 p.m. The stations are supervised by managers with six to eight years' practical experience in wireless work.

AGRICULTURAL RESOURCES OF FRANCE.—The *Echo de Paris* announces the publication of a book entitled "Effort Agricole de la France pendant les Six Mois de Guerre," from the pen of M. Fernand David, the French Minister of Agriculture. It contains very reassuring information respecting the present supply of cereals and cattle in France. At the end of last year there were 13,300,000 head of horned cattle in France, as compared with 16,800,000 head at the end of 1913. The number of pigs was 6,280,000, as compared with 7,080,000 a twelvemonth ago.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

APRIL 14. — T. THORNE BAKER, "The Industrial Uses of Radium."

APRIL 21.—MORETON FREWEN, "The State and the Fisherman."

APRIL 28.—A. S. E. ACKERMANN, B.Sc., Assoc. M.Inst.C.E., "The Utilisation of Solar Energy."

MAY 5. — AUGUSTUS VERNON HARCOURT, D.C.L., LL.D., D.Sc., F.R.S., "On the Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate."

MAY 12.—CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry." SIR ROBERT ABBOTT HADFIELD, D.Sc., F.R.S., will preside.

ADDITIONAL LECTURE.

Thursday afternoon, at 4.30 o'clock :—

MAY 6.—M. PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Constantin Meunier et les Sculpteurs Belges de son Temps."

INDIAN SECTION.

Thursday afternoons :—

APRIL 15, at 5 p.m. — PERCEVAL LANDON, "Basra and the Shatt-ul-Arab." The RIGHT HON. EARL CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., will preside.

May 13, at 4.30 p.m.—Sir Charles H. Armstrong, late Chairman, Bombay Chamber of Commerce, "Indian Trade and the War."

Colonial Section.

Tuesday afternoon, at 4.30 o'clock:—

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials." The Hon. Sir George H. Perley, K.C.M.G., Acting High Commissioner for Canada, will preside.

Date to be hereafter announced:—

C. H. Sherrill, "Ancient Stained Glass."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

David Sommerville, B.A., M.D., M.R.C.P., D.P.H., "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

MEETINGS FOR THE ENSUING WEEK.

Monday, April 12...Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Mrs. W. Maunder, "Astronomical Allusions in Sacred Books of the East."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Cleveland Institution of, Corporation-road, Middlesbrough, 7.30 p.m.

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Messrs. C. S. Joseph and R. S. Gardiner, "The Report of the Land Enquiry Committee on Housing."

Tuesday, April 13...Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. J. H. Rider, "The Power Supply of the Central Mining-Rand Mines Group."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. B. Fletcher, "The War on French Architecture."

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. Mr. C. W. Anderson, "On Impact Coefficients for Railway Girders."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. H. C. Cleaver, "Russian Peasant Art and Life."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. R. E. Crowther, "Thio-indoxyl Development and its bearing on the Theory of the Latent Image."

Zoological Society, Regent's-park, N.W., 8.30 p.m. 1. Mr. G. A. Boulenger, "A List of the Snakes of the Belgian and Portuguese Congo, Northern Rhodesia, and Angola." 2. Dr. R. Broom, (a) "On some new Carnivorous Therapsids in the Collection of the British Museum", (b) "On the Organ of Jacobson and its Relations in the 'Insectivora.'" 3. Dr. G. E. Nicholls, "A Note on the Urostyle (*Os Coccygeum*) of the Anurous Amphibia." 4. Mr. E. Gibson, "Some Notes on the Ñato Breed of Cattle (*Bos taurus*)."

Engineers, Society of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. F. Groves, "Main Roads, Past and Present, and Modern Methods of Construction and Maintenance."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Sir Gilbert Parker, "Lights and Lessons of the War."

Wednesday, April 14...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. T. Thorne Baker, "The Industrial Uses of Radium."

Geological Society, Burlington House, W., 8 p.m. Mr. S. H. Warren, "Further Observations on the late Glacial or Ponder's End Stage of the Lea Valley."

Automobile Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. F. W. Lanchester, "The Screw Propeller."

Japan Society, 20, Hanover-square, W., 8.30 p.m. Mr. N. Kato, "Eastern Ideas and the Japanese Spirit."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7.30 p.m. Mr. J. H. Rider, "The Power Supply of the Central Mining-Rand Mines Group."

Literature, Royal Society of, 20, Hanover-square, W., 5 p.m. Lecture by Dr. W. L. Courtney.

Thursday, April 15...Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. (Indian Section.) Mr. P. Landon, "Basra and the Shatt-ul-Arab."

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. Mr. C. F. M. Swynnerton, "Experiments and Observations bearing on the Interpretation of Form and Coloration in Plants and Animals."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. S. Eddington, "Star Colour and its Significance."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Rev. F. D. Morice, "Paradoxical modifications of Structure in Stinging-Insects and Sawflies."

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. Colonel J. W. Gifford, "Optical Instruments for Military Purposes."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. J. H. Rider, "The Power Supply of the Central Mining-Rand Mines Group."

Historical Society, 7, South-square, Gray's Inn, W.C., 5 p.m. Mr. F. A. Kirkpatrick, "The Spanish Municipal Administration in South America, 1500-1800."

Architects, Society of, 28, Bedford-square, W.C., 7.30 p.m. Mr. S. D. Chalmers, "Artificial Lighting in relation to Architectural Effects."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 8 p.m.

Friday, April 16...Royal Institution, Albemarle-street, W., 9 p.m. Mr. S. Graham, "The Russian Idea."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 8 p.m. Address by the President, Dr. W. C. Unwin.

Saturday, April 17...Royal Institution, Albemarle-street, W., 3 p.m. Colonel A. G. Hadcock, "Modern Artillery." (Lecture I.)

Correction.—A correspondent points out that in the article on "Production of Quinine in Italy" in the *Journal* of March 12th, 1915 (p. 379), in the last paragraph but one, a mistake was made in converting grammes to grains. The paragraph should read: "The average consumption last year, in Italy, of quinine manufactured by the State was 569 grammes (8779·67 grains) per 1,000 of population, as compared with 545 grammes (8409·35 grains) of the previous one."

Journal of the Royal Society of Arts.

No. 3,256. VOL. LXIII.

FRIDAY, APRIL 16, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, APRIL 21st, 8 p.m. (Ordinary Meeting.) MORETON FREWEN, "The State and the Fisherman." The RIGHT HON. WALTER H. LONG, M.P., LL.D., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PRESENTATION OF THE ALBERT MEDAL TO SENATOR MARCONI.

At the last meeting of the Council, on Monday afternoon, the 12th inst., Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.S.I., C.B., D.Sc., Chairman of the Council, on behalf of H.R.H. the Duke of Connaught and Strathearn, K.G., President of the Society, presented the Society's Albert Medal to Senator Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., "for his services in the development and practical application of wireless telegraphy."

In addition to the Chairman, the following members of the Council were present:—Sir George Ranken Askwith, K.C.B., K.C., D.C.L. (Vice-President), Sir Steuart Colvin Bayley, G.C.S.I., C.I.E. (Vice-President), Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D. (Vice-President), William Henry Davison, M.A. (Treasurer), Sir Steyning William Edgerley, K.C.V.O., C.I.E., Francis Grant Ogilvie, C.B., LL.D., Sir Westby B. Perceval, K.C.M.G. (Vice-President), Sir Boverton Redwood, Bt., D.Sc., F.R.S.E., Lord Sanderson, G.C.B., K.C.M.G. (Vice-President), John Slater, F.R.I.B.A., Alan A. Campbell Swinton, Carmichael Thomas (Treasurer), and Professor J. M. Thomson, LL.D., F.R.S. (Vice-President).

EXAMINATIONS.

This year for the first time the Examinations are being held twice. The first examination was held from March 22nd to 31st. The second will be held from May 10th to 19th.

As the entries for the May Examinations have been received, the figures for both are given below.

It will be seen that the total number of entries for both Examinations is 32,113. This shows a falling-off of 5,860 as compared with last year, when 37,973 entries were received. The large decrease is no doubt entirely attributable to the conditions prevailing throughout the country owing to the war.

March	May	Total.
Stage I.—Elementary.		
8,649	5,981	14,630
Stage II.—Intermediate.		
4,290	8,120	12,410
Stage III.—Advanced.		
1,488	3,585	5,073
14,427	17,686	32,113

In 1914 the figures were:—Stage I., 17,213; Stage II., 14,425; Stage III., 6,335.

The decrease in the different stages is:—Stage I., 2,583; Stage II., 2,015; Stage III., 1,262; Total, 5,860.

There were 221 Centres for the March Examinations, and there will be 252 for May.

Last year there were 406 Centres.

NORTH LONDON EXHIBITION TRUST.

In 1865 the Committee of the North London Working-classes and Industrial Exhibition (1864) presented to the Society of Arts a sum of £157, the balance of the surplus from that Exhibition, with a view to the annual award of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society of Arts. The Art

Workmanship Competitions were discontinued after 1870, but since that date various prizes have been awarded under this Trust. Prizes were offered to the students of the Artistic Crafts Department of the Northampton Institute, Clerkenwell, in 1903, and have been continued annually to the present time. These have been awarded, for the present year, as follows:—

Senior Section.—Prize of £2 and a Certificate to W. G. Cook, for an Engraved Plate.

Prize of £1 and a Certificate to A. W. Broderick, for an Engraved Plate.

Prizes of 10*s.* each and a Certificate to W. F. Elmore and to W. A. Hill, for Drawings and Specimens of Work.

Junior Section.—Prizes of 10*s.* each and a Certificate to A. Vecchione, for a Cloth Case, and to I. Chambers, for a set of Steel Dies.

The awards have been made on the recommendation of Mr. Alan S. Cole, C.B.

PROCEEDINGS OF THE SOCIETY.

SIXTEENTH ORDINARY MEETING.

Wednesday, April 14th, 1915; Capt. Charles E. S. Phillips, F.R.S.E., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Best, William Newton, M.Am.S.Mech.E., 11, Broadway, New York City, U.S.A.

Higman, Ormond, M.I.E.E., Electrical Standards Laboratory, Ottawa, Canada.

Jairazbhoy, Cassamally, Warden-road, Bombay, India.

Khan, Sahebzada Abdussamad, C.I.E., Chief Secretary, Rampur State, Rampur, United Provinces, India.

Mellor, Alfred, 152, West Walnut-lane, Germantown, Philadelphia, Pennsylvania, U.S.A.

Ram, Atma, Civil Lines, Ludhiana, Punjab, India.

Rumbough, John B., Enterprise Machine Company, 67-71, North Main-street, Asheville, North Carolina, U.S.A.

Smith, Miss Alice Maude, M.D., Chicago State Hospital, Dunning, Illinois, U.S.A.

Wilder, Gerrit Parmile, c/o Hawaiian Trust Company, Ltd., Honolulu, Hawaii.

Wilder, Leonard H., Ingleside, near McLean, Virginia, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Hitchins, Alfred Bishop, 194, Main-street, Binghamton, New York, U.S.A.

Maxwell of Calderwood, Lady (Jane), Glen Owen, Cheltenham.

The paper read was—

THE INDUSTRIAL USES OF RADIUM.

By T. Thorne Baker.

Radium has already passed through three stages in the way in which it has been regarded by the public. In its early days it was looked upon as something of a miracle, which was to revolutionise modern science, prove an endless source of power and energy, and act as a panacea for all human ailments; it was exploited by many quasi-scientific people, and very soon became regarded with something akin to suspicion. Then followed a period of forgetfulness as far as the public was concerned, while a great deal of careful, and apparently rather unproductive, research work took place, till it reached the third stage, when its applications to medical science became seriously recognised.

I want to put before you to-night a paper more suggestive than anything else. There seems little doubt that radium is destined to play an important part in industrial work as well as in medical science, and I hope to be able to give some instances which will indicate some of the possible lines on which radium may be employed in the near future.

A little over a year ago I had the pleasure of describing here some experiments which had been carried out in connection with agriculture; they were only of a preliminary character, but I am glad to say that they led to others making similar experiments, in many cases with very interesting results. It is not too much to say that in the hitherto worthless residues of the radium factories we have one of the most valuable agricultural assets of the country, which, if utilised with discrimination, will give a great impetus to intensive farming. Intensive culture in this country has hung fire, so to speak, because we do not like giving the almost paternal care to the work which is so absolutely essential; radium will, therefore, be particularly welcomed because the stimulus it gives to growth is so pronounced that intensive culture does not then require anything like the trouble ordinarily involved.

The early results obtained in plant and vegetable growing with radio-active soil have been up to the present uncertain, and therefore disappointing. During the last six months experiments carried out in warm laboratory germinators have elucidated many points previously doubtful, and I shall be able to show, as the result of experiments, how these

uncertain results arose, and how the uncertainty can be removed.

We have to remember, first of all, that radium is extracted from various kinds of mineral: where pitch-blende at first was the only source of supply we now depend far more upon carnotite, autunite and other minerals, containing very much less radium, but which are themselves far more abundant. Methods of extraction vary widely, as does their efficiency; and whereas some residues—after all the "available" radium has been extracted—contain 8 to 15 milligrammes of radium to the ton, others contain only 1 or 2 milligrammes per ton. Standardisation as regards "radium content" is thus obviously necessary; but what is of far more importance are the metallic compounds associated with the radium, and of course present in comparatively excessive quantities.

Radium is always associated with uranium in the proportion of about 3·4 parts of the former in 10,000,000 of the latter. In order to show the effect of uranium on vegetable life, I made some tests recently which gave very interesting results. Mustard seeds were sown in soil in test saucers and placed in a germination box. Lot A was watered three times daily with tap water; Lot B with a 1 per cent. solution of pure uranium nitrate, *i.e.*, uranium from which the radium had been extracted. The results were as follows:—

Lot A . . 82 per cent. of the seeds germinated.
Lot B . . 0 per cent. of the seeds germinated.

In other words, the uranium had proved fatal.

The experiment was then repeated, only this time Lot B was watered with a 1 per cent. solution of active uranium nitrate, *i.e.*, uranium nitrate containing the equilibrium amount of radium. The results were as follows:—

Lot A . . 81 per cent. of the seeds germinated.
Lot B . . 56 per cent. of the seeds germinated.

You will thus see that, despite the ordinarily fatal qualities of the uranium, the radium was able to give sufficient vitality to the seeds to enable 56 per cent. of them to germinate.

The importance of these experiments is that they show how necessary it is, if radio-active residues are to be used for agricultural work, that every impurity be known and, if possible, got rid of. A notable instance last year was that of a well-known seed firm, which carried out very numerous tests with radium residues, and got very great variations in the results, rendering the whole of the work somewhat doubtful. I found, on investigation, that the residues came from different sources, some containing copper and uranium, while one of the residues I happened to know contained no radium at all.

The ideal process of production for agricultural work is what is known as the concentration process. The residues, after full extraction on a commercial scale of the radium, are subjected to a method of concentration by which about 90 per cent. of the inert material is discarded; the whole of the radium content is then found in the "concentrates," so that in any case any deleterious matter is reduced to one-tenth of the normal. But it so happens that in this process the heavier matter is discarded, so that a good deal of metallic residue is done away with, and there is very little in the final product but radium contained in silica.

These concentrates are, however, not always available, but it may be taken for granted that the vanadium, uranium, or copper is usually extracted before the "residue" stage; on the other hand, weak radio-active earth supplied from the neighbourhood of radium mines will very probably contain uranium or copper, or both, and will then be unsuitable for obtaining the best results. By fusion with crude caustic soda, or by vigorous boiling with alkaline carbonate, the radium and barium are obtained as insoluble carbonates; these are usually dissolved next in hydrochloric acid, and the radium barium chloride either precipitated as sulphate, or precipitated directly by the addition of sufficient concentrated hydrochloric acid.

It may be emphasised here that, in agricultural work, soluble radium salts in very small quantities completely kill soil organisms, and that the use of too liberal a quantity of insoluble radio-active matter is almost fatal to plant life. I have found that 1 cc. of a 1 : 25,000 solution of pure radium bromide in 10 cc. of culture medium entirely prevents the growth of ordinary soil bacteria.

In agricultural, and, I think, other types of industrial work with impure radium, or radio-active residues, we shall always have to consider two things: (1) The influence of the associated impurities; and (2) which of the rays emitted are responsible for the effect produced.

Radium gives off three types of ray, the α, β, and γ. The α rays are absorbed by a thin sheet of note-paper, the β mostly by a sheet of lead 1 millimetre thick; the γ rays have very great powers of penetration. The β rays are about 100 times as penetrating as α rays, while γ rays

are 10 to 100 times as penetrating as β rays. In order to determine the effect on germination, tests were made in earthenware saucers with mustard seed, the saucers being placed in the electric germinator. This germinator consists of a stout metal or wood box, electrically heated, with glass shelves at different heights, and adequate temperature control. The seeds were subjected to a temperature of about 28° C. for sixteen hours a day, and about 15° C. during the remaining eight hours.

In test A the seeds were sown in ordinary mould, as a control; in test B also ordinary mould was used, but the seeds were watered with radium emanation water, which gives only α rays; in test C the seeds and soil were placed over radium barium chloride, with a sheet of card 1 millimetre thick separating it, so that the β and γ rays were effective; while in test D a sheet of lead 3 millimetres thick was interposed, so that γ rays alone could influence the germination.

The result of the radium emanation water was very marked, as 100 per cent. of the seeds germinated, and the seedlings grew in each case at a uniform rate. In the control test about 90 per cent. of the seeds germinated, but, as is common in these cases, the growth was erratic, about half the seedlings developing normally, the other half being dwarfed by lack of vitality. The α rays of radium, especially when administered in the form of emanation water, have always, in my experience, shown a very pronounced tendency *to increase the vitality of plants.*

Although not much difference is to be detected between the action of the β and γ rays, the β rays seem to produce a more deleterious effect than the γ rays; this is not remarkable when we consider the effect of the X-rays, which are very largely identical with the β rays of radium, in their destructive power on micro-organisms. The β rays are also present in far greater abundance.

The importance of these experiments is that they show that: (*a*) The α rays are largely responsible for increased vitality and quicker germination, hence the great advantage of sowing the seeds in earth prepared with the radio-active matter; (*b*) the emanation is of value to plant growth, and hence, if radio-active matter is laid over the soil, the rain, or the watering, will produce to some extent emanation water which will sink through the earth, reach the roots, and hence be of benefit in accelerating growth.

A convenient form of apparatus for preparing emanation water on a cheap scale is shown in the diagram on the screen. Radio-active material, insoluble in water, and containing 200 or 300 milligrammes to the ton, is packed between fine muslin stretched over wooden frames, and these frames are placed vertically, an inch or two apart, in an enamelled iron tank provided with a tap at the bottom and a well-fitting cover at the top. The tank is filled with water, left for a week or a fortnight, and the water then drawn off as required. By having two such tanks, used on alternate weeks, a continuous supply can be easily obtained.

A more simple apparatus is shown in the photograph on the screen. This is very well suited for laboratory experiments, and is easily put together. A filter flask, of 2 litres capacity, is provided with a delivery tube and tap, the tube projecting to below the surface of the water inside the flask, and a scent-spray bulb is fitted to the tube at the side, so that when pressed the water is driven by air pressure through the delivery tube. At the bottom of the flask is distributed on the largest possible surface 5 grammes of finely divided precipitated radium barium sulphate of about 1 in a million concentration, and the flask is a quarter filled with 500 c.c. of water. For germination tests, milk and cheese experiments, and so on, I have found this a most useful little apparatus, and the emanation experiments above described have all been done with water prepared in it, leaving the water in contact with the radium barium sulphate for one month before use.

I believe that it is legitimate at this Society to make a reference to trade matters, and I should like to refer to a radio-active fertiliser with which I have been experimenting for some three years, known for industrial purposes as "Nirama." This consists of radio-active matter from which practically the whole of the deleterious inorganic matter has been extracted, and after the radium content has been definitely ascertained, it is diluted to a uniform standard with finely sifted and sterilised soil. In order to cope with the demand of the plants, owing to their rapid growth, for more chemical nutrition, nitrogen and phosphoric acid are added in suitable forms, and the effect is in many cases to get anything up to 100 per cent. quicker growth, with noticeable moistness and fullness, as against coarseness and bitterness in taste which often result from hasty or too abundant growth.

Provided uniformity as regards radio-activity be obtained, and sufficient chemical manure be employed to let the plants take the full advantage of the radium stimulus, there is little doubt that this type of fertiliser will be found to play a highly important part in future agricultural chemistry.

We now come to the more practical side of the question, viz., can radio-active compounds be procured on a sufficiently large scale, and at a sufficiently low cost, to render their use possible on an industrial scale?

The present price of pure radium bromide ($RaBr_2.2H_2O$) varies from £18,000 to £25,000 per gramme, or £18 to £25 per milligramme. As the type of residue best suited to agricultural work contains about 2 milligrammes to the ton, and the residue itself is valueless, a ton of material would cost at the outside about £36. As a matter of fact, when buying residues or low-grade ores, the price per milligramme is far smaller, and an average price of £5 per milligramme may be taken as a reasonable basis. Thus £5 would represent the cost of the radium in about 40 tons of soil, and 40 tons spread over or worked into the ground to the depth of from 3 to 5 ins. would obviously cover a very large area of ground. I know of one lump in this country where 2,000 milligrammes in residues are lying idle; this would make 80,000 tons of soil permanently suitable for intensive cultivation, and we can imagine what even this would mean to a small country like England at a time when market gardeners are straining every nerve to increase their yields.

I do not wish to touch on the medical aspect of radium except in two instances, which are, I think, of considerable interest. The first of these is in connection with baths. It is well known that a great number of people went annually to such resorts as Karlsbad and Gastein, where radio-active water is available for baths or for drinking purposes. Very marked results have been obtained in cases of gout, neuritis, rheumatism, and so forth. Where radium water has been administered in this country it has been in the form of emanation water, for the preparation of which large quantities of fairly pure radium salts have been necessary. The emanation water, besides losing its radio-activity in less than six days, emits only α rays—two obvious limitations.

In experimenting with salt furnaces last year, at Carrickfergus, I found that dilute radium salts, *i.e.*, for example, radium barium sulphate containing one part in one million of radium element, was completely soluble in molten salt, and on dissolving a small measured quantity of a radium barium salt in a quarter of a ton of molten sodium chloride subsequent tests showed that homogeneous mixture had taken place. By the process of manufacture in use at Carrickfergus, the molten salt is poured from the furnace into a rotating iron pan; several rakes, or iron pegs, fixed as to position, project into the salt and keep it broken up and also gradually direct it to the periphery of the pan. It is then, in a fine state of division, carried over into an endless band of pans, which empty into graded sifting screens. The fine particles of salt, on being tested both in the α-ray electroscope and by the emanation method, exhibited uniform radio-activity, and on being dissolved in tap water gave an exceedingly finely-divided precipitate of radio-active particles, which easily remain in suspension for some time.

Salt so prepared, and containing approximately 1·375 milligrammes of $RaBr_2.2H_2O$ to the ton, is now being extensively used under the name of "Rabasa" for medical baths, and several officers who have come back from trench life at the front suffering from acute rheumatism have been treated with highly satisfactory results. It is hoped that this salt will, to a large extent, do away with the necessity for visiting Continental bath resorts, but, what is of more importance, it will bring a modern and highly valuable process of therapeutics within the reach of those who hitherto have been unable to go to the expense of radium treatment in Germany.

During the last two years a great deal of active work has been done in the eradication of the fungi attacking what is known as split cod, essentially a Norwegian industry, but one also of growing importance in Great Britain. Cultures I obtained in 1913 from storehouses, drying-sheds, and diseased fish at Christiansund, in the north of Norway, where an immense quantity of cod is dried on the rocks in the sunny months, showed a peculiar behaviour to high-frequency electric currents—apparent inhibition at first, always followed by a marked increase in the rate and profusion of growth. Radio-active salt appears far more effective, and I am hoping this year to be allowed to test its value here with the courtesy and help of the Fishery Board for Scotland.

The effects of radium on bacteria and on fermentation, etc., have already received a considerable amount of attention, but their possible application to industrial bacteriology

is worthy of careful study. The effect of electricity on milk is, of course, well known, although by no means perfectly understood. A thunderstorm, for example, will turn milk sour, presumably by the rapid increase of growth of the acid bacteria it contains. In milk of bad quality as many as 124 million bacteria have been found to the cubic centimetre, or, roughly, 60,000 million to the pint. One bacterium can, by simple fission, become two in twenty minutes, under normal conditions. Under suitable electrical conditions the bacteria would double their numbers in a few minutes. Hence it is not difficult to see that milk not too fresh could be "turned," or become sour, in a very short time when under electrical influence. The α rays of radium consist of positively-charged particles, and their effect may thus be analogous to the positive electricity which is so beneficial to plant life and to many bacteria. Tubes of milk stood in highly concentrated radio-active matter, the β and γ rays penetrating the glass, but in each case there was very little result. If, on the other hand, milk is slowly filtered through a layer of insoluble radio-active matter, and the milk bacteria are brought into contact with the α radiation, a very rapid effect is noticed, the milk clotting within a short time. In other words, radium is able to take the place of the ferment rennet, and may therefore prove of value in the manufacture of cheese. I hope that this reference to the cheese industry may induce others to investigate these possibilities.

The fact that an intermittent current of about 30 to 50 milliamperes passed for ten minutes through milk will cause it sometimes to keep in good condition at 25° C. for three days, is significant of the extraordinary effect of certain types of electrical influence on inhibiting the growth of the lactic acid bacteria, and probably the bacillus coli communis and the other micro-organisms present. Recent preliminary tests have shown the presence of soluble radium to be highly effective in increasing the rate of alcohol production by fermentation, while too much radium again inhibits the growth of the ferment or destroys it.

Radium has, in certain instances, a distinct bactericidal action, and we shall probably find, as its properties become more closely understood, that besides possessing very selective action, stimulating some bacteria and inhibiting the growth of others, it will assist growth when used in minute quantities, and prove fatal when more concentrated. Some tests recently made with a common air staphylococcus, the organism grown in culture media containing

(*a*) 10 per cent. of a 1 : 25,000 radium bromide solution;

(*b*) 10 per cent. of a 1 : 2,500,000 radium bromide solution;

(*c*) the control culture medium;

gave the following results:—

(*a*) No growth after five days at 27° C.

(*b*) Fair growth after five days at 27° C.

(*c*) Normal growth.

A good deal of work will probably be done in the near future in the design and manufacture of radium emanation water apparatus. Ingenious devices are already manufactured by which water is filtered very slowly through a porous block, in the material of which is incorporated radio-active matter of just the necessary strength to emanate it during its passage through. These have also been made in the form of syphons.

Common methods in America are to precipitate the sulphate on asbestos and place the latter in a porous cell, and to mix it with charcoal and form "slabs."

There must be an advance in these things, however, as soon as it is more generally recognised that dilute radio-active matter, very much less expensive, can be used with equal success for the purpose, and I think that the slow progress made in this direction is due to the fact that the medical scientific man usually buys pure radium salts at standard prices for making emanation, and the weaker material remains in the hands of the radium factories, and has not been sufficiently exploited.

Take, for example, some quotations recently made:—

(Practically) pure radium bromide, $RaBr_2 . 2H_2O$, £18,000 per gramme.

Radium barium salts, about 2 milligrammes per kilogramme of radium bromide, £9,000 per gramme.

Slightly less concentrated, containing iron also, but in an insoluble form, £7,500 per gramme.

Residual matter, about 8 milligrammes per ton, £4,000 per gramme.

Now, according to recent experience, the latter material could be employed quite well for preparing emanation water, and it seems a matter for regret that more enterprise is not shown in dealing with this class of material, as radium treatment (for internal administration in the form of water) is at present a luxury, except in hospital work.

The usual strength employed in medical treatment is 1 millicurie to the litre of water. The amount of radium emanation in equilibrium with 1 gramme of radium is called a curie. One-thousandth of this amount, therefore, in the litre of water, is the usual strength, though water containing 6 millicuries per litre has been used in certain cases.*

It is interesting to note here that about $\frac{1}{50}$th or $\frac{1}{25}$th of a millicurie per litre seems the most advantageous to employ for agricultural work.

Radium emanation, as is well known, has a life period of under six days, and falls to half its strength in 3·85 days. The decay is shown in the curve on the screen. In order to obviate this trouble, radium chloride has been successfully administered on the Continent, in the form of tablets, which, of course, retain their entire strength almost indefinitely. The dose used has been about 2·4 by 10^{10} milligrammes, three times a day for several days.

I recently attempted to increase ionisation of mercuric chloride by the introduction into a solution of it of sufficient radium sensibly to increase its electrical conductivity, as one of the existing theories as to the powerful disinfectant powers of mercuric chloride is that the mercury becomes ionised in solution, and is responsible for its bactericidal action. Dr. Andrews very kindly tested these solutions for me at St. Bartholomew's Hospital, and found that the increased ionisation did not increase the action of the mercury. This is of interest incidentally, as it tends to show that the ionisation theory, relating to bactericidal action, on which very divergent views are held, is not correct.

There is little doubt, however, that radio-activity in suitable amount will be utilised in mouth-washes and tooth-powders and pastes, on account of its antiseptic powers when employed at a certain strength. One hears reports sometimes of its powers to cure baldness; but I will not deal with this, as it is not an industry, but something of a fine art!

Another practical use to which radium is being put is the preparation of watch, clock, and compass hands, to render them luminescent in the dark. A year ago such luminous hands were more or less a novelty, but the present war has demonstrated their very real use, and thousands of watches with luminous hands are now being sold. I believe that luminous sign-boards are also in use in Russia, and some time ago there was some agitation to try them in this country. That they will come is very probable.

It is a peculiarity of most of these substances that they must be in the crystalline state to be active. Zinc blende, or sulphide of zinc, in the form of hexagonal crystals, becomes phosphorescent when excited with radium; diamond is similarly excited, also barium platinocyanide, calcium fluoride, and the double sulphate of uranium and potassium.

Crystalline zinc sulphide, usually employed in the preparation of clock and watch hands, is known as Sidot's blende. It occurs in crystalline form in nature, and is not easy to prepare artificially. It can be made, however, by igniting zinc oxide in a current of sulphuretted hydrogen gas, or by heating precipitated zinc sulphide in a stream of the gas. The crystalline structure is not always apparent when prepared in this way, but the desired optical properties are obtained nevertheless.

The luminosity is produced by means of actual scintillations, each α particle emitted by the radium in contact with zinc sulphide producing one scintillation. Professor Wood * has calculated that the duration of luminosity produced by each scintillation does not last more than $\frac{1}{10000}$ of a second. On the other hand, 1 gramme of radium expels $6 \cdot 2 \times 10^{10}$ (over 60,000 million) α particles per second,† so you will see that a very small quantity of radium goes a very long way in producing the luminescence. The β rays of radium produce sustained luminescence of some minutes' duration.

Consequently, luminous paint of permanent luminosity can be prepared commercially by mixing zinc sulphide with radio-active material. It would appear, however, that on account of its relative cheapness, meso-thorium is being largely employed at present. Meso-thorium is produced as a by-product in the incandescent gas-mantle industry. It has a life period of only seven to nine years, as against 2,500 in the case of radium; but, on account of its cheapness, it will probably be more largely manufactured than radium in the future.‡ The result will be that the life of a really good watch or clock will be longer than that of the luminosity of the hands, and this is a point worth consideration by the purchaser who is paying a big price.

One further possible application of radium to industrial work I should like to mention is its use in the preparation of photographic

* C. E. S. Phillips. "Radiography, X-ray Therapeutics and Radium Therapy," R. Knox, p. 843.

‡ Soddy. "The Chemistry of the Radio Elements," p. 68.

emulsions. The early experimenters with radium used to test the radio-activity of substances by its fogging effects on a photographic plate. Kinoshita showed in 1910* that each α particle of radium acting on a photographic plate rendered one "grain" of silver bromide capable of development, and that the action went on until the whole of the grains within range were affected.

It seems a somewhat bold suggestion, therefore, to mix actual radio-active matter with a photographic emulsion; but I have been able recently to produce emulsions containing a suitable quantity of radium chloride or bromide which yield much denser and more vigorous photographs under test conditions, with the important result that *normal* brilliance in photographs can be obtained by the use of less silver in the emulsion—an economy of far-reaching importance.

In conclusion, I must apologise for the somewhat scrappy and versatile character of this paper, but I have brought it before this Society with two objects: First, to induce, if possible, more enterprise among works' research chemists to test the availability of radium for their own industries; and, second, to point out that in a time of national emergency we have large stores of material, at present lying idle, which could be turned to enormous advantage for agricultural work.

DISCUSSION.

Mr. Martin H. F. Sutton exhibited specimen plants of peas and beans which he had tested with the author's material, "Nirama." In the case of the peas there was but little difference between the controlled and the dressed plants, but, as the audience would see, in the case of the beans there was a very distinct difference. The really interesting point of the test was in the germination. He had brought to the meeting the results of his trials with the material on rape. He had used sand alone, and sand plus "Nirama"; and in the latter case apparently every single seed germinated, and the seedlings came through the sand with the help of "Nirama" three days before they came through the sand alone. From the tests his firm had made, they thought there was certainly something in radio-active material. What it was, or how far it was likely to be useful, they could not at present definitely say. His firm had published a bulletin of what they had done in the matter during the past summer, and anybody interested could obtain a copy by writing to him. What his firm had used during the last summer had been two distinct ores from different sources, and also a slime from the same source as one of the ores came from. During the present year their trials would be considerably more complete.

Professor F. Keeble, F.R.S., desired to emphasise the point that it was greatly to the detriment of science that premature claims should be made for results or for effects, which might in course of time be demonstrated, and which might prove to be of great importance, but which were not yet justified by any results which had been made public. In that respect he was confining his criticism entirely to the suggestions and claims which had been made for radio-activity, or the effects of radium on plant growth. He confessed he was not in a position to explain that very remarkable result which had just been referred to by Mr. Martin Sutton in connection with some of his exhibits, but he would point out that the incubus of explaining that fact did not rest on himself or any other scientist, because no experiment in the strict sense of the word had been made. A certain material, with a name which he had for the moment forgotten, containing, in addition to the substance to be experimented with, a number of unknown chemicals, among others nitrogen compounds and phosphates, had been employed. It was well known that nitrate in certain forms was a great activator as well as a food for the growth of plants; and how much the effect of that precocious growth of the rape was to be ascribed to the radium emanations, and how much was to be ascribed to the unknown nitrogen compounds employed, could not be definitely stated. Judgment must be reserved for the time being as to whether that experiment was destined to contain the germ of a fertile idea. A word of caution should be expressed with regard to the advice given by the author, that all the waste stuff from the radium factories which was lying about this country should be utilised. There was as yet not anything like sufficient evidence to justify any serious horticulturist or agriculturist in spending a penny piece on exploiting radium. A good deal more work would be required to be done before anyone would be in a position to speak confidently as to whether radium emanations produced any effect, and whether that effect was mainly good, or whether it was partly good and partly deleterious. In making that criticism, he had had the privilege of following very closely the experiments which had been carried out by Mr. Sutton, and neither that gentleman nor himself, nor others who saw the experiments, could convince themselves that the effects were more than those which might be ascribed to chance, although there was always a presumption that radium might be doing a certain amount of good. He did not think they even got so far as even considering whether the effects were worth the expenditure of money on the materials. It was important that a warning should be given, because the market had

* *Proceedings* of the Royal Society, A. 83, p. 432.

been flooded by all sorts of stuffs which claimed to be radio-active, and horticulturists and agriculturists were being asked to put their hands into their pockets and pay considerable sums for substances which might or might not be of any use whatsoever.

Mr. B. H. Rolfe supported the views of the last speaker, at any rate in one sense. All who had worked in radium had suffered from violent anticipations which had been made by unauthorised persons as to what could be done. That had been a millstone which had weighed heavily round investigators' necks. With regard to the question of the effect of extraordinarily dilute radium bodies in agriculture, he did not think it had been quite brought out in the paper how very minute those bodies were. For instance, carnotite ore contained, as it was at present, somewhere about 5 or 6 milligrammes of radium to the ton, which had a relation, he might put it, of a second of time to three years. At present somewhere about 85 per cent. of that was taken out, so it could be gathered that the amount left was very minute. That stuff had been used apparently very successfully for agricultural purposes. It had only been done on an experimental scale, but there was one question in connection with it where the last speaker's point came in. There was in that material a certain small residue of vanadium, and vanadium acted to a certain extent as a fixer of the atmospheric nitrogen, and investigators had not yet been able to make up their minds completely as to how much the effect was due to the radium and how much to the other. He thought he might mention some exceedingly interesting experiments which had been carried on at Manchester University by a German student on the germination of barley. That student had found that by keeping his barley under certain conditions, and circulating round it an atmosphere which contained a small quantity of the actual emanation, he got his barley to germinate much more quickly than it would have done otherwise. That certainly suggested that the action of the emanation, if there was enough of it, tended in that direction. That experiment had been checked in a number of ways, and if, unfortunately, that excellent work had been interrupted, still it was a very direct point made in that particular line.

The Chairman (Captain Charles E. S. Phillips, F.R.S.E.) said he would like to point out one small matter which the author had overlooked in giving his long list of the possible applications of radium to commercial matters, and that was a device which was at present in use in the North in connection with the industry of weaving. He had not seen the actual apparatus at work, so he could not describe it in detail, but he believed there was a certain stage in the weaving of thread in which a number of very fine filaments came off in all directions, and very easily attached themselves to parts of the apparatus or the machine through which the thread was passing, owing to the fact that those threads became highly electrified. A very simple and practical way had been devised of overcoming that difficulty, by passing the thread through a tube, upon the inner surface of which was a small quantity of radium, or other radio-active matter. The result was that the air inside the tube became ionised, and the electricity on those fine filaments was at once taken off, and went to earth (the tube itself being connected to the earth); thus the whole difficulty of those filaments flying out in all directions and attaching themselves to various parts of the machinery was completely eliminated. The author had said a good deal about intensive culture, and the great speed at which beans, and possibly other agricultural products, could be grown, but there was one question which he should like to ask, namely, whether the author had investigated the radio-activity of the products at all? For instance, was any of the radium which was in the soil drawn up into the plants themselves? If so, was it quite safe, even supposing the growth of cabbages, and corn, and so on, could be accelerated? With regard to milk, he would remind the author that the results of some careful experiments in that direction had been published before the Röntgen Society, about two years ago, by Professor Duffield. In those experiments the idea had been to try to produce artificially the same conditions, in the neighbourhood of milk, as were associated with thunderstorms. The results were very inconclusive. Mr. Thorne Baker, however, seemed to speak with almost too much confidence as to the results of the clotting of milk by alpha rays, and the increase in the growth of bacteria owing to the conditions associated with thunderstorms. Professor Duffield had tried pumping ionised gas through milk, making sparks in its neighbourhood, and trying to reproduce the conditions of a thunderstorm on a small scale, but with no definite result. He (the speaker) had actually gone so far as to pump radium emanation through milk without producing any sign of clotting. The rate of the development of acid in the milk seemed to be unaffected by the presence of radium emanation. A paper had been recently published dealing with the question of the treatment of certain diseases of the teeth with radium—by means of emanation water. In all these efforts the point that struck one very forcibly was the extreme smallness of the quantities of the material made use of. One might perhaps be allowed to express a certain amount of scepticism over such results where the amount of material used was so extremely small in relation to the large effects which seemed to be produced. If it were possible to increase the growth of a plant, then it seemed reasonable to suppose that by some radio-active means it might be possible to stimulate the growth of other forms of organic cells. He thought there was only one investigator who was of the opinion that the growth of organic cells could be directly stimulated

by means of radio-activity, so that, again, showed the author had taken upon himself a very great responsibility in expressing with such certainty some of the results which were being dealt with by a large number of other men all over the world with a feeling of great doubt. He was sure the author appreciated how difficult it was to make a satisfactory experiment with anything, and the trouble of eliminating the numerous factors which must assuredly enter into matters dealing with the growth of plants, especially under the conditions which had been described. The point was, could the matter be put on a strict laboratory basis? Could the experiments possibly be made in such a way as to eliminate every other influence except the radio-active one? The action of the alpha particles seemed to be one which tended to destroy cells. The idea that the cells should be stimulated to develop and to subdivide, and that the plant growth should be accelerated by means of radium was, of course, nothing more or less than a miracle, because it seemed to be almost impossible to form any basic theory as to why such a result should come about.

THE AUTHOR, in replying to the remarks of Professor Keeble, said he should like to draw attention to one thing which had been very obvious from the results of a very large number of carefully carried out tests, and that was when the radium was mixed with a sterile soil it almost invariably appeared to act better without any nitrogen and phosphorus, or nitrates and phosphates, than with them, except in isolated cases. He was referring to 150 recent germination tests, and in all cases the radium in the necessary strength, or in the strength used, gave apparently the best results. One thing which made him feel more confident than perhaps it would have been wise to be about the effect being due to radium, was that so many of the other effects which were produced were comparable with the effects produced when the crops were electrified. Some analyses made last year of radish grown in radio-active soil showed an increase in the amount of sugar produced of between 30 and 40 per cent., which was very much the same as the increase of sugar obtained in earlier experiments. The reason the material referred to in the paper had been made was not that he desired to push it as a manure or fertiliser, but since he had read his last paper before the Society some fifteen or sixteen months ago, owing to the extraordinary circulation of the *Journal* of the Society, hardly a week went by without one or two people writing from different parts of the world asking where they could obtain radio-active residues; and the point he had tried to emphasise in the paper that night was that if radio-active residues were obtained through a third, fourth, or fifth party, very likely the purchaser would get large quantities of inorganic chemicals with it, which would render entirely impossible the obtaining of accurate results. The point about the preparation was simply that it was standardised as regards its radium content, and that it could always be obtained, if further tests were wanted, in uniform quantities. He thought that, as the tests which had already been carried out showed promise of good results, it was very desirable for larger tests to be instituted, because tests in the open were not always the same as tests in agricultural laboratories. He would like to see forty or fifty acres of ground treated on a large scale. The Chairman had raised the interesting point as to whether plants grown in radio-active soil contained any radium themselves. If the experiments carried out were of any value, it seemed obvious that the best results were obtained with emanation water, or with the alpha rays, and if the results could be obtained with emanation water, which was going to decay in the ordinary time, it was not likely that any products would be left in the plants. He had touched on the milk experiments because he thought it was a matter of some interest, but he quite agreed that not very much could be done, because of the extraordinary variation in milk itself. The question of chief importance was, were the results obtained actually due to radium or to something else which was associated with radium? With regard to the importance of carrying out tests on a much larger scale than they had hitherto been carried out, if whatever was associated with the radium was responsible for the improvement, and not the radium itself, it seemed to him none the less desirable to prosecute the research because that stuff might just as well be used if it gave such good results.

On the motion of the CHAIRMAN a hearty vote of thanks was accorded to the author for his interesting paper.

EMPIRE NOTES.

British and Canadian Trade.—Some valuable suggestions were made by Mr. C. Hamilton Wickes, His Majesty's Trade Commissioner in Canada, in an address recently delivered in the Council Room of the London Chamber of Commerce. on "Trade with the Dominion of Canada and the Empire," on the methods which should be adopted by British manufacturers and merchants if they desire to secure a larger measure of Canadian business. The Canadian market, he said, was one in which the weak points of British methods of trading were strikingly apparent. Canada stood out clearly and distinctly from Australia, South Africa and New Zealand, as in the Canadian market the British manufacturer had to do without his nurse—the export commission house. Secondly, he had to meet the competition of the United States firms, who were better placed, both strategically and geographically. The American manufacturer paid attention to direct marketing and the question

of production in quantities, which, as a rule, was not the custom of British firms. He summarised as the chief obstacles to British trade: (1) the fact that Canadian firms want manufacturers to call and do business with them direct. (2) The existence of United States' standards, which have been accepted by or imposed upon Canadians. (3) The large number of United States magazines and newspapers carrying advertisements of American firms, which find their way into Canada. (4) The fire hazard standard for buildings and fittings, which had to be passed by the Underwriters' Laboratory of Chicago. The Trade Commissioners' office, however, had secured the appointment of a representative of the Laboratory in London, where British makes of building fittings could be inspected and passed. (5) The expense of travelling and the variations of climate in so large a country as Canada. In the matter of organisation, Mr. Wickes suggested that provision should be made for the creation of an Intelligence Department on a large scale. A directory of manufacturers was also needed, and a system should be adopted for the investigation of Imperial sources of supply, particularly in regard to primary products. Firms should be registered as well as companies, and there should be greater co-operation between bankers and manufacturers in this country. Referring to the prospects for the coming season, Mr. Wickes said it was estimated that the wheat crop in Canada would amount to 245,000,000 bushels, and that the financial return would be about 40 per cent. greater than last year. The harvesting of such a crop should tend to relieve the financial situation, but this would not make itself felt until 1916. For the months immediately ahead, caution should be the watchword. Trade might not be more, and would, perhaps, be less in volume than last year, but conditions were moving towards better business. Mr. Wickes is prepared to advise traders at the Commercial Intelligence Branch of the Board of Trade in London during his stay, and he proposes also to visit various provincial centres.

Gold-mining in Western Australia.—The gold production in Western Australia for last year amounted to 1,232,977 ozs., valued at £5,237,353, which is equal to 51 per cent. of the annual gold production of Australia. Speaking in the Western Australian Parliament recently, the Minister of Mines stated that there was a better feeling in the great gold-mining centres, Kalgoorlie and Boulder, than had existed for the past five years. The "Golden Horseshoe" is down to a depth of 2,800 ft. and has struck a rich ore body at that level. The "Golden mile," between Kalgoorlie and Boulder, is still the richest mile of gold-producing country in the world. The State batteries of Western Australia have in fifteen years recovered gold to the value of £4,303,372, almost entirely won from ore sent for crushing by prospectors and small lease owners, with insufficient financial resources to erect their own plants. The Minister estimates that the mining industry pays nearly two and a half million pounds in wages annually.

Railway Progress in New Zealand.—Considerable progress is being made in the construction of the North Auckland Trunk Railway, and a further section from Otamatea to Bickerstaffe will be handed over to the New Zealand Railway Department by the Public Works Department shortly. At present 320 men are employed on the work, and two tunnels are under construction. The station buildings at Bickerstaffe, eighty-three miles seventy chains from Auckland, are practically completed. Ballasting and plate-laying have progressed up to Muddy Creek Bridge, three miles further ahead, and the bridge is completed. Gangs are at work as far north as ninety-two miles sixty-seven chains, many of the men being engaged in tunnel construction. The Mangaturoto tunnel, which is twenty chains in length and eighty-seven miles distant from Auckland, will shortly be pierced, there being only a length of two chains separating the drives. Cuttings are being opened out at a point ninety-one miles forty chains from Auckland, preparatory to commencing work on the Huran tunnel, which will be 297 yards long. There is still another tunnel beyond the Huran, known as the Golden Stairs, and it is anticipated that the earthworks ahead of these tunnels will proceed simultaneously with the completion of the Huran tunnel. The new Parnell tunnel (double track) between Auckland and Newmarket is virtually completed. This tunnel, which will replace the old single-track bore, enabling the latter to be utilised as an approach to the waggon and coach-building shops at Newmarket, is 1,122 ft. long, 25 ft. 9½ ins. wide, and 19 ft. 6 ins. high. With its completion, the working of the heavy traffic between Auckland and Newmarket will be greatly facilitated.

Hydrographic Work in Canada.—The Annual Report of the Department of Naval Service for 1913–14 contains reports on the Survey of Tides and Currents and on the Hydrographical Survey branch, summarising the work accomplished during the year. As regards currents, the most important observations were those in the northern passes of British Columbia, notably at Seymour Narrows, carried out in the interests of the large coast traffic of that region, and also of the international traffic to Alaska. Valuable results were obtained in reference to the tides in Hudson Bay and Strait. From a series of observations at Ashe inlet in the latter, it was found that the tide in Hudson Strait is similar to that in the Bay of Fundy, and that, as the

tidal difference between Ashe inlet and St. John, N.B., are remarkably constant, a satisfactory means is available for computing the tide in the Strait. Progress was also made towards the provision of tide-tables for Nelson and Churchill in Hudson Bay, by establishing the relation between the tide at those places and at western European ports. Thus, the tide at Churchill can be calculated direct from that at Harwich, to which it is remarkably similar, with a constant difference. Of the hydrographic work, that carried out in Hudson Bay by a party under Mr. F. Anderson is of interest. This work was done in the new survey steamer "Acadia," built at Newcastle-on-Tyne, which arrived just in time to be used for the purpose. She was specially strengthened for use in ice, and proved quite successful, though some plates were seriously indented, showing that merchant vessels will incur risks in navigating the bay and straits unless strengthened. Little ice was met with in the straits on the outward voyage, but closely packed winter ice was encountered well on in August, sixty miles off Port Nelson; and on the return voyage heavy ice caused serious trouble on October 22nd, damaging a merchant ship. In view of such dangers from ice, it is held to be important to establish depots of provisions and fuel on the inhospitable shores of the straits. As a result of the surveys carried out, there is now a chart, embracing an area of some forty-five miles off the entrance to Port Nelson. Other parties were at work during the year on the Pacific Coast, on Lakes Superior and Ontario, on the Lower St. Lawrence, and in James Bay. A large amount of sounding had been done and various plans made. In James Bay observations were made of the break-up of the ice in Moose and Rupert Rivers; that in the former being marked by a big flood.

Inoculation against Typhoid.—In view of the importance of the subject of inoculation against typhoid during the war, and its application to general hygienic conditions where masses of men are gathered together in construction and lumber camps, the experience of the Canadian Pacific Railway Company is of more than passing interest. It appears that in their railway construction camps, typhoid is one of the forms of disease most to be guarded against, and that, for this purpose, the company has found the use of the anti-typhoid serum to be of the greatest service. Last year alone 11,722 employees were vaccinated on the western lines, and amongst those only four cases of typhoid developed, one of which proved fatal. Among the men not inoculated, sixty-two cases developed of which nine proved fatal. On the Alberta division eleven cases of fever occurred in a camp situated within the city limits of Calgary, containing thirty-five men who had refused to be vaccinated. After the cases developed they all asked to be treated, with the result that only one death occurred. Before the campaign for inoculation was instituted by the company's doctors, several hundred cases occurred, on an average, annually. The comparative freedom which the employees of the company now enjoy from the disease is cited, and may well be cited, as an evidence of the value of the anti-typhoid serum, which is supplied to the men free.

South Africa and the Indian Question. — The settlement of the status of Indians in South Africa comes at an opportune time, and the Union Act, according to the Secretary of State for the Colonies, has been welcomed by His Majesty's Government as embodying a genuine and sincere attempt to remove those disabilities of the Indian population of the Union which had kept alive a sense of grievance and discontent, not only in South Africa, but in India. The Government of India, it is stated, have expressed their gratification at finding in the recommendations of the Indian Inquiry Commission, to which effect, in conjunction with administrative action, is now to be given by this Act, a very complete and satisfactory attempt to arrive at a final solution of the difficulties that have arisen in South Africa. The Secretary of State further says that His Majesty's Government have learned with pleasure that this Act, coupled with the agreement with Mr. Gandhi, regarding the administrative action to be taken by the Union Government, has been accepted by that gentleman as finally closing the passive resistance struggle which began nearly eight years ago, and they confidently believe that the spirit which has animated both parties to the controversy, and which alone has rendered settlement possible, will continue to make itself felt, and will render easy the solution of any difficulties which may arise in the future. This is specially gratifying, in view of the more sympathetic feeling which is growing up throughout the Empire towards those races in India and elsewhere, living under the British flag, who have so willingly offered, and are now giving, their services to the King-Emperor and to the maintenance of the Empire itself of which they constitute so important a part.

The Progress of Fiji.—Some interesting facts, showing the progress and prospects of Fiji, were given in the address of the Governor to the Legislative Council some time ago, in which he stated that the cost of the Agricultural Department had increased from £665 in 1905 to £6,244 (estimated) in 1914. Referring to a recommendation made in his address in 1912, that planters, who have suitable land and sufficient funds at their disposal, should experiment in the cultivation of limes, he pointed out that the lime industry of Dominica in the West Indies was valued in 1912 at £97,142, and that the area of land under lime cultivation was only

3,300 acres, which gave an approximate return of £30 per acre. Canada, the United States of America, Australia, and New Zealand, he said, afforded ready markets for the sale of limes both ripe and green, lime-juice, citrate of lime, and essential oils, so that the permanent character of the lime industry must commend itself to those agriculturists who desire a safe investment for their capital and could afford to wait four or five years until the first crop could be gathered.

CORRESPONDENCE.

EXTERMINATION OF FLIES AND MOSQUITOES.

With regard to the extermination—or, at all events, the discouragement—of mosquitoes, it may be of interest to state that at Honolulu, some years ago, the experimental growing of a species of *Lemna* (duckweed) was tried on small surfaces of water, with a view to preventing female mosquitoes from gaining access to the water for purposes of depositing. I understand that the experiments were successful in demonstrating the efficacy of the method. The duckweed leaves become so closely matted together on the surface of the water, and the roots beneath it, that it is virtually impossible for any insect to penetrate the skin thus formed. Not many years ago I recollect seeing a mill-dam on the Avon, near Coventry, of large extent, absolutely covered with a species of duckweed. So thick and firm was the skin, that numbers of moorhens were walking about on the surface.

G. Bertram Kershaw.

OBITUARY.

Samuel George Smith, M.A., D.D., LL.D.—The death of Dr. Samuel G. Smith, of St. Paul, U.S.A., took place on March 25th, after a short illness.

Dr. Smith was born at Birmingham in 1852. While he was still a child his parents went to America, his father, who was a Methodist minister, having taken a missionary post in Iowa.

At the age of seventeen Samuel Smith was in charge of the public schools of Jessup, Iowa, and at twenty he was principal of the Albion Academy, Iowa. He afterwards attended Upper Iowa University, finishing his course at Cornell, from which he graduated in 1872. He then entered the Methodist ministry, and was called in 1879 to the pastorate of the First Methodist Church of St. Paul, where he continued until 1888. In that year he founded the People's Church, with which his name has since been closely associated, and for the endowment of which he succeeded in raising a fund of $100,000 in 1918.

Dr. Smith's activities were by no means limited to his church work. He took a deep interest in social, political and moral problems.

In 1889 he was appointed a member of the Board of Charities and Corrections. A year later the University of Minnesota called him to organise a department of sociology and anthropology. He was placed in charge of it, and continued as head of the department, giving lectures and conducting classes until a few months ago. The department has been a leader in its field, and its methods have been copied in numerous universities and colleges.

As a member of a State Commission he made a trip to Europe in 1892 to inspect penal and charitable institutions, and brought back ideas, several of which were incorporated in Minnesota institutions.

He was one of the pioneers also in anti-tuberculosis work in Minnesota, being identified with the various organisations engaged in the fight against the disease.

As a criminologist and champion of penal reform, Dr. Smith was one of the leaders of the nation. He was a member of the National Conference of Charities and Correction, and the National Prison Association, of both of which he had been president. Dr. Smith also was a member of the State Board of Visitors for five years, from 1907 to 1912.

Another subject in which he took a deep interest was eugenics. He was a delegate to the International Eugenics Congress in London in July, 1912, where he made one of the principal addresses.

He made some twenty journeys across the Atlantic and back. His travels took him into all parts of Europe. He spent much time studying in foreign universities and seats of culture, as well as learning the social and economic conditions in foreign lands. He twice was offered the pastorate of the Westminster Chapel in London, the largest and one of the wealthiest Nonconformist churches in London, but refused, preferring to carry on the work he had begun in St. Paul.

Dr. Smith was a prolific writer. Among his works is a book on "Social Pathology," issued in 1911, which is being used as a text-book in schools and colleges all over America. Other books of wide circulation are "The Industrial Conflict," "Religion in the Making," "Democracy and the Church," and "Retribution and other Addresses."

He was elected a Fellow of the Royal Society of Arts last autumn.

NOTES ON BOOKS.

Dew-Ponds. By Edward A. Martin. London: T. Werner Laurie, Ltd. N.d. 6s. net.

In the spring of 1909 Mr. George Hubbard read a paper on "Dew-ponds" before the Society, in which, adopting the old theory of their origin and nature, he recommended their more general use in waterless regions.* This paper was followed by a good deal of discussion,

* See *Journal*, LVII. p. 330.

at first in the columns of the *Journal*, and afterwards in the *Field* and *Nature*. The author of the work under review took part in this discussion, and in a contribution to *Nature* he rather controverted Mr. Hubbard's views on several points, the most important being the question whether the water in the pond, after being heated during a summer day, can ever fall in temperature below the dew-point. Aided by a grant from the Royal Society, Mr. Martin continued and extended the series of experiments on which his views were founded, and the present work is the result of his further investigations.

He not only made a number of observations on existing ponds, but had an experimental pond constructed of the orthodox type, with a layer of straw and other non-conducting material below it. The result of the observations made, and the information collected, was that, in the author's opinion, the surface water would never in warm weather cool down to the dew-point, and that consequently, even when there was abundant dew on the surrounding herbage, none would be deposited in the pond; that the straw, etc., could never be kept dry, and that therefore it soon lost its non-conducting powers, which further were of no value since they did not enable the water to cool down, even if they did cut off the access of heat from the earth; and, finally, that the source from which the upland ponds were filled was fog and mist, aided by rain, and in occasional cases by drainage.

Incidentally, Mr. Martin arrived at the conclusion that there is no justification for attributing any very great age to any existing pond. While admitting that prehistoric man may have used "naturally-puddled pools where four-footed beasts came to quench their thirst," and may have constructed ponds with puddled clay bottoms, he can find no evidence of his having made any existing pond, or of his ever having constructed a scientific straw-bottomed pond at all. All such ponds, he says, if neglected, become useless. Grasses and rushes thrust their roots through the puddle, they cease to be waterproof, dry up, and are overgrown so that nothing but an empty hollow remains.

It is sad to think that the prehistoric dew-pond, which has supplied alike the cattle of our præ-Roman ancestors and the sheep of our contemporary shepherds, is but a charming myth. But so Mr. Martin will have it, and it rather looks as if he were correct.

ESSENTIALS OF ENGLISH SPEECH AND LITERATURE. By Frank H. Vizetelly, Litt.D., LL.D. New York and London: Funk & Wagnalls Company. $1.50 net.

In this volume Dr. Vizetelly gives—to quote his own sub-title—an outline of the origin and growth of the language, with chapters on the influence of the Bible, the value of the dictionary, and the use of the grammar in the study of the English tongue. Nor does this comprehensive description exhaust the scope of the book, for the final chapters deal with phonetics, pronunciation, writing for publication, individuality in writing, and the corruption of speech. It will be obvious at once that such a vast field can only be hurriedly surveyed in the space of 400 pages. Thus, the sketch of English literature is of the slightest: Shakespeare is dismissed in eight pages, Milton in six, while, of course, it is only the Tritons who are mentioned in the text; the minnows must content themselves with having their names and dates recorded in an appendix.

To this criticism the reply, no doubt, would be that there are plenty of histories of English literature, and that this book does not claim to be one of them. Indeed, Dr. Vizetelly specially disavows any pretence to exhaustiveness. His aim—and it is a praiseworthy one—is to enable the student to determine with ease the different periods in the evolution of the language, and to provide him with a succinct guide to the important writers of each period. If the volume succeeds in inducing any of its readers to a serious study of English language and literature, it will have justified the labour which Dr. Vizetelly has clearly spent upon it.

THE MOTOR CYCLIST'S HANDBOOK. By "Phœnix." London: Percival Marshall & Co. 2s. net.

The first edition of this handbook was published in 1911; since then over 17,000 copies have been sold, and now a fourth edition has been called for. It is easy to understand the popularity of this book, for it is extremely practical, is written by one who is a complete master of his subject, contains everything that a motor cyclist wants to know, and nothing that will be useless to him.

Probably no industry is making more rapid strides at the present time than the manufacture of motors. This edition, which is thoroughly up to date, contains therefore a good deal that is fresh. Owing to the growing popularity of the two-stroke engine, considerable additional space has been devoted to the discussion of the two-stroke principle, and a large folding plate has been prepared to illustrate the construction of an engine of this type and the manner in which it works. A new chapter on cycle-cars has also been added.

GENERAL NOTES.

THE PUBLIC TRUSTEE.—The seventh general report of the Public Trustee shows that the business of his department continues to expand. The number of new estates and trusts which have been accepted in 1914 is 1,548, having a value of

£11,623,429, while the Public Trustee has also been informed that he has been appointed to act as executor in wills prepared and executed during the year disclosing an estimated future value of nearly £10,000,000. The total amount of business undertaken since the opening of the office in 1908 is £132,061,159. The financial stability of the department has been well maintained. The fees for 1914 reached a total of £65,374, as against £55,283 for 1913; while the expenses have reached a total of £61,234, as against £49,612 for 1913, providing a surplus of income over expenditure on the year of £4,140. A portion of the increased expenditure for the past year is due to the establishment of a branch in Manchester. It is satisfactory to learn that the staff, who have loyally carried out their onerous duties, have now been appointed members of the established Civil Service. The staff includes 213 male officers; of these not less than 71, or 33 per cent., are at present on active service in various capacities.

Motor-cars in Norway.—Until the outbreak of the war the autocar industry in Norway was limited to the coach work solely, whilst the *chassis* and other mechanism were obtained from foreign makers. The finished cars were principally imported from Germany, France, England, the United States, with a few from Italy and other countries. This trade, however, during the present crisis, is at a very low ebb, and a very small number have been imported since last August. A great impetus to the introduction of the motor vehicle in Norway has been given of late by the improvement of the roads throughout the country. Previous to 1913, the total length of roads practicable for motor traffic in Norway did not exceed 2,953 kilometres (1,831 English miles); their length, at the present time, has greatly increased, and now reaches a length of 4,318 kilometres (2,677 miles). In 1913 the total number of vehicles propelled by motors was only 972, as compared with 1,553 last year, showing an increase of 581, or 60 per cent. on the number of the previous year. The use of the autocar is increasing all over the country, even in the most remote districts, for the conveyance of passengers and goods. In all the principal towns autocars are taking the place of horses. At Christiania alone there are 462 auto-vehicles in use at the present time; of these, 279 are passenger cars, 85 lorries or vans, and 98 motor-cycles.

The Indian Leather Trade.—Before the war the raw hide business of India was, with a few exceptions, in the hands of Germans. In the years 1911, 1912 and 1913 the normal export of hides to Bremen and Hamburg was about 3½ million cow hides annually, and these ports took over 2½ million cow hides in the first six months of 1914. In addition to exports to Bremen and Hamburg, nearly 1½ million hides passed annually from India through Trieste, and to this port the first six months of 1914 brought 1,178,466 hides. In the total these three enemy ports drew from India in three years and a half 11,335,905 cow hides.

Flour-milling Industry in Japan.—H.M. Commercial Attaché at Yokohama reports that the flour-milling industry in Japan has developed remarkably of late years, and the fact that the flour now imported is principally confined to the first grade shows that second-grade goods can now be produced in Japan. The production of wheat flour in Japan in the years 1911, 1912, and 1913 amounted to 25,396,205 yen, 28,827,512 yen, and 32,694,146 yen respectively, or, expressed in British values, to about £2,592,500, £2,942,800, and £3,337,500 respectively. Along with this development of the milling industry, the demand for wheat has been greatly stimulated, and, according to the latest estimate, the annual consumption of wheat is 2,600,000 koku (12,896,000 bushels), of which some 400,000 koku (1,984,000 bushels) is imported, mainly from the United States. The imports of wheat flour for 1911, 1912, and 1913 amounted to 1,702,951 yen, 1,722,140 yen, and 1,780,065 yen respectively, or, expressed in British values, to about £173,800, £175,800, and £181,710 respectively. The export of Japanese wheat flour is not very large, the value for 1913 amounting only to about 3,400 yen (about £347), but a drawback of 70 sen (about 1*s*. 5*d*.) of the import duty of 77 sen (about 1*s*. 7*d*.) per 100 kin (about 132½ lbs.) of wheat being now allowed on the export of wheat flour made from imported material, the exports are thought to be likely to increase.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

April 21.—Moreton Frewen, "The State and the Fisherman." The Right Hon. Walter Hume Long, M.P., LL.D., F.R.S., will preside.

April 28.—A. S. E. Ackermann, B.Sc., Assoc. M.Inst.C.E., "The Utilisation of Solar Energy."

May 5.—Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., "On the Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate."

May 12.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry." Sir Robert Abbott Hadfield, D.Sc., F.R.S., will preside.

Additional Lecture.

Thursday afternoon, at 4.30 o'clock :—

May 6.—M. Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Constantin Meunier et les

Sculpteurs Belges de son Temps." LORD SANDERSON, G.C.B., K.C.M.G., will preside.

INDIAN SECTION.

Thursday afternoon:—

MAY 13, at 4.30 p.m.—SIR CHARLES H. ARMSTRONG, late Chairman, Bombay Chamber of Commerce, "Indian Trade and the War."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

MAY 4.—S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials." The HON. SIR GEORGE H. PERLEY, K.C.M.G., Acting High Commissioner for Canada, will preside.

Date to be hereafter announced:—

C. H. SHERRILL, "Ancient Stained Glass."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Syllabus.

Chemical Constitution of Foodstuffs—Proteins—Carbohydrates — Fats — Inorganic Substances—Colloids and Crystalloids—Metabolism—Enzymic Action in the Alimentary Canal.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 19...Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. Professor J. H Moulton, "The Zoroastrian Doctrine of a Future Life."

Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. P. Dan, "Advertising as applied to the Brewing Industry."

Electrical Engineers, Institution of (Local Section), Mining Institute, Newcastle, 7.30 p.m. Mr. V. H. Mackinney, "Illumination."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. (Junior Meeting.) Mr. H. J. Smith, "Trade Claims in Compensation."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. S. Owen, "The Design and Construction of Buildings for Industrial Purposes."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. H. Marsh, "Indirect Benefits of Irrigation not generally recognised."

TUESDAY, APRIL 20...Statistical Society, 9, Adelphi-terrace, W.C., 5 p.m. Sir E. Brabrooke, "The Progress of Friendly Societies and other Provident Institutions during the ten years 1904–1914."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. B. Fletcher, "The War on Rheims." (Lecture II.)

Photographic Society, 35, Russell-square, W.C., 8 p.m. Captain O. Wheeler, "Some New Telephotographic Appliances—with Examples."

Engineers and Shipbuilders in Scotland, Institution of, 39, Elmbank-crescent, Glasgow, 8 p.m.

Roentgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. 1. Dr. N. S. Finzi, "Late Radium and X-Ray Burns." 2. Mr. F. H. Glew, "A New Alpha Ray Effect." 3. Mr. A. O. Forder will exhibit a New Plate Holder.

WEDNESDAY, APRIL 21...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. M. Frewen, "The State and the Fisherman."

Meteorological Society, at the Institution of Civil Engineers, Great George-street, S.W., 7.30 p.m. 1. Mr. H. H. Clayton, "A Study of the Moving Waves of Weather in South America." 2. Mr. E. H. Chapman, "The Correlation between changes in Barometric Height at Stations in the British Isles."

THURSDAY, APRIL 22...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 8 p.m.

Chemical Society, Burlington House, W., 8.30 p.m. 1. Messrs. G. T. Morgan and J. W. Porter, "The constitution of internal diazo-oxides (diazophenols)." 2. Mr. N. V. Sidgwick, "A method for distinguishing tautomeric from polymorphic substances." 3. Mr. S. U. Pickering, "Metallo-compounds in solution." 4. Messrs. G. Senter and H. D. K. Drew, "Studies on the Walden Inversion. Part I.—The influence of the solvent on the sign of the product in the conversion of phenylchloroacetic acid to phenylaminoacetic acid." 5. Mr. A. J. Allmand, "The energy distribution in the radiation from the Uviol-glass lamp." 6. Mr. E Newbery, "Electromotive forces in alcohol. Part VI.—Absolute potentials by the capillary electrometer." 7. Mr. J. E. Purvis, (*a*) "The absorption spectra of the vapours and solutions of anisol, phenetol, and various derivatives"; (*b*) "The absorption spectra of the isomerides of ammonium d-*a*-bromo-camphor *β*-sulphonate." 8. Messrs. A. McKenzie and S. T. Widdows, "The racemisation of phenyl-*p*-tolylacetic acid."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. S. Eddington, "The Stellar System in Motion." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. E. S. Bruce, "The Aeroplane and its Use in War."

Concrete Institute, 293, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. F. E. Wentworth-Shields, "The Stability of Quay Walls on Earth Foundations."

FRIDAY, APRIL 23...Royal Institution, Albemarle-street, W., 9 p.m. Major P. S. Leban, "Military Hygiene at the War."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Professor W. B. Morton and Miss M. Darragh, "On the Theories of Voigt and Everett regarding the Origin of Combination Tones." 2. Miss M. Saltmarsh, "Experiments on Condensation Nuclei produced in Gases by Ultra-Violet Light." 3. Mr. S. Butterworth, "On the Self-induction of Solenoids of Appreciable Winding Depth."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 8 p.m.

SATURDAY, APRIL 24...Royal Institution, Albemarle-street, W., 3 p.m. Lieut.-Colonel A. G. Hadcock, "Modern Artillery." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,257. VOL. LXIII.

FRIDAY, APRIL 23, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

NEXT WEEK.

MONDAY, APRIL 26th, 8 p.m. (Cantor Lecture.) DAVID SOMMERVILLE, B.A., M.Sc., M.D., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, "Foodstuffs." (Lecture I.)

WEDNESDAY, APRIL 28th, 8 p.m. (Ordinary Meeting.) A. S. E. ACKERMANN, B.Sc. (Engineering), Assoc.M.Inst. C.E., "The Utilisation of Solar Energy." CHARLES VERNON BOYS, F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, April 15th, 1915; The RIGHT HON. EARL CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., in the chair.

THE CHAIRMAN said it was the custom of those presiding at the Society's meetings to say a few introductory words about the reader of the paper, but such words on his part that afternoon need not be of an introductory character, as Mr. Perceval Landon needed no introduction to any person in the room. Mr. Landon had long been known to all who were interested in the East as a writer of exceptional ability on Eastern and other questions, and he was an authority second to none on the geography and politics of what was commonly called the Middle East. When he (the Chairman) was in India he had the good fortune to be able to allow Mr. Landon to go with the expedition to Tibet. The result was, as all knew, the best book which was in existence upon that expedition and upon that country in modern times. Mr. Landon also wrote a very admirable book upon India itself; and with regard to the countries which he was going to describe that afternoon Mr. Landon himself was a personal visitor to them in the years 1908 and 1912, so that he would speak with that knowledge which personal experience alone could give. Lastly, Mr. Landon was the master of a very vivid and picturesque style, and it might be taken as certain that it would be true of his paper that afternoon—what was not true of all papers—that it would be vastly more interesting than the slides by which it was illustrated.

The paper read was—

BASRA AND THE SHATT-UL-ARAB.

By PERCEVAL LANDON.

I.

There is at least one advantage in taking the town of Basra and the Shatt-ul-Arab as the subject of a paper. It is impossible to detain an audience long with the topic that seems sometimes to possess a fascination for lecturers—the antiquities of the place. Although the Shatt-ul-Arab is within a short distance of the centre and cradle of the earliest developed civilisation of the world, it has no ancient history at all. As a glance at the map will show, in the third millennium before Christ the kingdom of Sumer came down to the Gulf; the two great seaports were Eridu and Ur. That these towns were actually on the sea is clear from a record of about the year 2350 B.C., in which the scribe of Dun-gi, Lord of Ur, notes that his master cared much for Eridu, "which is on the shore of the sea." Four centuries later the great law compiler Khammurabi, King of Babylon, issued orders that troops should be embarked on ships at Ur. The coast-line of the Persian Gulf extended in those days a very long distance to the north-west and north of the present shore. It is indicated on the map by a dotted line.

Before going on, it may be of interest to recall that Abraham left Ur of the Chaldees on his epoch-making journey through Haran to the

Land of Canaan at almost exactly the time at which these orders of Khammurabi were issued. We are not usually disposed to regard Abraham as a longshoreman, but there can be no question that the pastoral life must have been entirely new to the greatest of all patriarchs. When, with his father Terah, he left Ur on a journey that was destined to leave an indelible result upon the world's history, the bleating of sheep and the lowing of kine were alike unknown to him. He had been accustomed to the bustling life of a primitive seaport, the smell of tar and seaweed, and the large talk of sailors.

In his time the site on which Basra now stands was covered by the waters of the Persian Gulf. But it can only have been just covered, and, before turning to later days, it is worth remembering that the account of the creation of the world, as we find it in the first chapter of Genesis, was originally compiled by a scribe of the land of Sumer who was manifestly indebted for his relation of the workings of the Creator to the actual process continually going on eastwards under his very eyes. Little by little the currents of the Euphrates, which of course was then entirely unconnected with the Tigris, were confined in their channels and the dry land appeared. It is, perhaps, not pressing the theory too far if it is suggested that the subsequent story of the growth of grass and of the date palm—and surely we may so interpret the phrase, "the fruit tree yielding fruit after his kind whose seed is in itself"—describes with exactness the gradual coming of vegetable life upon the shores of the Shatt-ul-Arab as they slowly arose from the waters of the Gulf.

II.

So far as we know, the town of Basra was founded by the Caliph Omar about the year A.D. 636. Its rise must have been rapid, as two hundred years later it was the seat of the Christian bishopric of the Persian Gulf. As the seaport of Baghdad it soon became famous, as is proved by the Arab Odyssey, better known to us as the "Voyages of Sindbad the Sailor." The city from which this hardy traveller made his famous departures was not exactly on the site of the present town. Old Basra was placed twelve miles south-west of the European or riverine quarter of Basra to-day, and therefore seven or eight miles south-west of the older quarters of the present town. This earlier Basra was in communication with the Gulf by a canal linking it with the inlets now known as the Khor Zobeir and the Khor Abdalla, and it was through this channel that merchandise was brought in lighters to and from Basra

It is only within living memory that a stretch of mere treacherous swamp has been reclaimed along the bank of the Shatt-ul-Arab, and the European quarter of modern Basra built on piles upon it. It is not uncommon to find Basra referred to as the Venice of Mesopotamia. I am afraid, however, that, as I shall show you in a few moments, the fact that the two towns are built upon piles is the only resemblance between them, and that is not a resemblance that leaps to the eyes.

The importance of Basra lies in the fact that it occupies the nearest site to the open sea which is capable at once of supporting the roadways and houses of a large and populous town on land, and of admitting ocean-going ships to its quays. Calcutta is a parallel. The reclaimed river-bank, upon which is the substantial British consulate and the quays and warehouses of Messrs. Lynch and other merchants, is almost the only part of Basra that demands political attention at this moment. But Basra is more than the river-bank. The place has up to the present suffered from what are probably the two worst disadvantages that can handicap any Eastern town. Its position as a clearing-house and distributing centre—which almost inevitably attracts the dregs of humanity —and the fact that it has been for centuries subject to Turkish rule, will explain at least to this audience the unattractive population and administrative chaos that have been observed by visitors to the town. Possibly there is not a worse governed city in Asia. The Arab has— well, has never been encouraged to develop the art of municipal government. The Turk knew himself to be an intruder in the place. He knew the precariousness of his tenure, and with characteristic Ottoman energy every official determined to make the most of a fleeting opportunity. If I may, I will tell you three stories to show the way in which the responsibilities of government were until lately interpreted in this outpost of the Turkish Empire. There was a Vali of Basra who made the up-to-date proposal that an electric tramway should be constructed along the bank of the Ashar Creek, which extends from the old town to the river. In anticipation of this boon he went so far as to collect much blackmail, partly from the owners of houses which might be benefited, partly from the owners of houses which might be seriously interfered with if the line took a certain course, over which he had, he said, much control. The tramway has not yet been made.

On another occasion the British consul at Basra received repeated complaints from the Vali that a buoy at the mouth of the Shatt-ul-Arab had become misplaced. The consul at once took action, and after some trouble secured the promise of the assistance of H.M.S. "Palinurus" to re-survey the place and replace it. At once the Vali refused to give his consent that the buoy should be touched. I do not know, but I suppose that the buoy was surreptitiously replaced in its right position, but nothing more was heard of it.

There was once a customs official at Basra who demanded dues payable, as he asserted, upon the delivery of a parcel at Bahrein. He still went on claiming them after the question had been referred eighteen times to Constantinople, and eighteen times they had been admitted by the Turkish authorities to be irrecoverable.

Such has been the atmosphere in which Basra has still succeeded in becoming one of the most promising seaports in the Middle East, and that it is destined to be yet more important we may read between the lines of Lord Hardinge's recent speech at Basra, in which he said that the people might look forward in the future to a more benign administration. The fact is, that Basra is geographically and commercially the inevitable centre of the Gulf market.

III.

It has already been said that the site of Basra is due to the fact that it is the lowest stable position at which sea-going ships can unload their cargo. Its importance is also due to the self-evident fact that the shortest line

and the line of least resistance in tracing a course between East and West, between East and Middle East, runs up the Persian Gulf and takes to the land among these alluvial flats.

The early fame of Basra may be suggested by a reference to the voyage of an Englishman, Mr. John Eldred, at the end of the sixteenth century. He was a merchant adventurer, and collected his cargo during the six months that he spent in Basra. On March 26th, 1588, having successfully evaded the naval activity of King Philip of Spain, he arrived home "in the 'Hercules of London,' which was the richest ship of English merchants goods that ever was knowen to come into this realme." As a specimen of the great value of these Eastern cargoes, it is worth while perhaps to give an idea as to how it was transported, and of what it consisted. Eldred chartered a flotilla of seventy barges to take his treasures up the river to Baghdad. To carry it thence across the desert of Aleppo he required 4,000 camels. It consisted of the following things—and I hope that this Society will forgive me if I spend two minutes in reminding them of the wealth of the East by the simple means of reading aloud a Manifest, which, in addition, for sheer music of words is hardly to be surpassed in the English language; and the spices give a pleasant smell between the lines.

"Spikenard from Zindi and Lahore; Cloves from Maluco, Tarenate and Amboina, by way of Java; Nutmegs from Banda; Sinnamon from Seilan, and Wild Sandals from Cochin. Verzini was there from St. Thomas; Quicksilver and Rock Alum from China; Ginger from Dabul, Sorat, Mordas and from Mecca; Coral of Levant from Malabar. Galls had been collected from Cambaia and Bengal; White Sucket from Zindi; Corcunia and Zedoari from divers places in India; Requitria and Myrrh from Arabia Felix; Sal Armoniacke, Costo dolce and Indico from Zindi and Cambaia. Brimeo, which is near to China, contributed Camphor; Borax and Asa Fetida were wrung from Lahore; Seragni, Opoponax and Tutia were the offerings of Persia; Storax calamita from Aneda and Canemari, within Karamania; Bengal sent Wax; Cagiers from Malabar and Maldiva. Rufia to die withal was packed at Chalangi; Chopra at Cochin; Demmar was brought from Sciacca and Blinton; Lac from Pegu and Balagvate; Bdellium—how the Bible rings in this great list!—from Arabia Felix and from Mecca. From Basra itself came Chomin, Tamarinds and Safran; from Sokotra, Aloes, Incense and Dragons' blood; Diu served up its coarse bales of Terebinthe, all for the delight and luxury of England. Masticke from Sio; Opium from Pugia and Cambaia; Ambrachan and Lapis Lazuli, Orpiment, Galbanum, and Chochenillo, Manna from Mecca, and Scamonea. Nor did Eldred forget Galangae, Melleghete and Saracolla with many other spices, of which the very names smell like a garden of herbs; and that the maidens of London should have their sweetmeat, Pistaches Dates and Muske of Tartary."

IV.

We have seen that Basra was an important market at the end of the sixteenth century. It must not be supposed, however, that it lay directly upon any one of the old mainland routes between East and West. These routes ran almost inevitably to the north and east to Basra. Until about the date of John Eldred no one dreamed of going to China or to India except by the road which passed through Tabriz. According to his choice a man might leave Constantinople north east by the Crimean route or east by the Erzerum track. Both paths met at Tabriz. Thence one road struck due east through northern Persia to Bokhara and Samarkand and on to the territory of the Great Khan. The other, turning sharply to the south, skirted the Persian desert, touched at Kashan and Yezd, and reached the sea near Hormuz on the Persian Gulf.

Yet some adventurous souls made for Basra. It is a matter of some doubt whether on their second journey the Polos did or did not descend the Tigris and reach Basra, but it was not the usual route. Probably in those days it was easier to obtain protection at a price from a land chieftain than to secure immunity from the pirates who swarmed at sea. After the Polos Friar Odoric turned aside from the main road, about 1320, and paid a visit to the Shatt-ul-Arab. What struck him most was that the women were unkempt and barefooted, while the men were well dressed. Both sexes lived chiefly upon dates. Marino Sanuto, a little before that time, had noted that the best quality of spices were already being exported to Europe through the Shatt-ul-Arab, while the heavier and commoner spices went round by Aden and the Red Sea. Schiltberger adds little to our knowledge of ancient Basra. We may now turn the page on the older history of the town.

V.

One may approach the Shatt-ul-Arab to-day from three directions—from the Persian Gulf,

from the Tigris, and from the Karun. The date is not far distant when there will be a fourth route along the line of the Euphrates. I mean the Baghdad Railway. In the sixteenth century Basra was a clearing-house of spice. To-day it is a carfax of what may become the most important highways between the east and the west. Indeed, it is hardly too much to call it the solar plexus of the old world. I do not forget the Suez Canal. But what I should like to lay stress upon is the fact that, the Suez Canal being now, and as I hope for good, under the control of the more civilised Powers of Europe, no mistake must be made by leaving open to those who have elected to become our enemies a postern gate—a postern gate which may in time rival in importance the great wet doorway that Ferdinand de Lesseps broke open between Europe and the East. Before considering its importance to ourselves, I should like to give some idea of the existing roads to Basra. I have said that they are three, with the probability of a fourth. But there are others. Besides the Mohammera-Khoramabad track, there are trans-Arabian desert roads which are not as unimportant as might be gleaned from an inspection of maps, geography primers, and Blue-books. The trans-Arabian route is, perhaps, destined to become a railed highway before most of us die.

May I say here that one of the most serious losses that we have sustained during this war has been the death of Captain W. H. Shakespear, whose daring work in Central Arabia has, perhaps intentionally, been fully appreciated by but few. More nearly than any other official he was the Richard Burton of our day, and his death at the very moment when the historic feud in Arabia between Ibn Rashid and Ibn Saud seems to be drawing to its close deserves far more than this passing reference.

VI.

First I will take the approach to the Shatt-ul-Arab by the Persian Gulf. I should like to say something of which it is scarcely necessary to remind this audience. The present monopoly which we possess upon its waters and on its shores—a monopoly not so much of material benefit as of hard work—has been due in a large manner to Lord Curzon. Throughout the early and more hazardous years of the efforts of Prussia to intrude itself into the Gulf, the responsibility for action and insistence lay with him as Viceroy of India, and that we remain therein with our rights and our responsibilities intact is due more to him than to any other living Englishman.

I do not want to repeat here the story of Berlin's persistent attempts to create the simulacrum of German interests in and near the Gulf. They have been well summarised recently by the *Times*; and I can recommend no more serious reading to those who appreciate the importance of our work in Mesopotamia than certain pages in the twenty-ninth part of the *Times* "History of the War."

To these persistent efforts Berlin devoted its subtlest methods of intrigue. By the appointment of consular representatives who did not represent as many souls as would fill one side of a London omnibus; by subsidies and by bribes; by representations to Turkey—which were of the same nature as those which in November of last year induced that unfortunate country to take part in the present war; by attempts to tamper with the loyalty of Sheik Mubarak of Koweit; by sheer "maintenance" of Ibn Rashid of Hail; in short, by every conceivable means of thrust and bluster Prussia has attempted to gain a foothold here.

On the other hand, our own predominance in the Gulf has been secured by eternal watchfulness, a display at times of naval strength, and recently by the addition of one more to the many shades of political understanding that our large Empire includes. The term "special relations" has been applied to our Imperial reciprocity with the chieftainships of Koweit and Mohammera; and, vague as it appears, there is perhaps no single asset—except our command of the sea—which will be more useful to us at this important juncture than the long-standing—nay, the almost traditional—friendship that exists to-day between the Government of India, between the naval forces in the Gulf—between, indeed, any travelling Englishman and the venerable Sheiks Mubarak of Koweit and Khazal of Mohammera.

But our claim is deeper than this. It lies in the fact that for a century we have done the work of the Gulf. We have cleared it of pirates; we have sounded and surveyed it; we have charted, buoyed, and lighted it; we have opened it to the commerce of the world; and there is not a peaceful keel in the wide seas that might not have furrowed its waters in tranquillity without tax or due. We interfere with none, so long as legitimate commerce is kept distinct from political hostility. But we are the stewards of this great highway, and while all the world may use it, no one but ourselves

shall have the right or the responsibility of policing it.

The gun-running in the Gulf, which is now at an end, was centred in Muskat.

[I am throwing these pictures on the screen, not because they will present much that is new to this audience, but because I think it necessary that, if the facts of Southern Mesopotamia are to be well understood, we should, so far as possible, forget the atmosphere of London, even of the Adelphi, and live for the moment, as far as light and darkness can help us to do so, in the external surroundings of the Gulf, the river, and the plains.]

We may abuse the gun-runners, but we must remember the temptation that was offered to them. At any gunsmith's shop in the little suburb of Matra—and the shops were of ominous frequency—you could get a serviceable rifle for £3 10*s*. Now, if you can get that rifle to the Afghan frontier you can sell it for £30. This is no time to consider the incidental effects of this war, but one fact at least is certain, and that is that the turbulent Pathans inside the Durand line will in future have to look elsewhere than to Muskat for their weapons.

Of the other towns in the Gulf it will be sufficient to show you their unvarying external character by a photograph of one of them, Lingah. There is a great similarity between them, though in journeying up one is in turn confronted by the sullen antagonism of Debai, the long vanished glories of Hormuz, the watchful friendliness of Lingah; Bahrein, with its mysterious tombs, where the pearls come from, and where the only fresh water is obtained from the springs at Khor Fasht and Buhir which bubble up through the salt waves of the Gulf. Bahrein is a kind of Monte Carlo of the Gulf. Fortunes are quickly won and lost at pearling, and the visitor realises the high standard of living even before he lands, for he will be asked seven rupees—nearly ten shillings—for the trip in a native boat between the ship and the beach. On the opposite shore to Bahrein, Bushire is the terminus of the road from Isfahan through Shiraz to the Gulf, a road which the raids of the Kashgais and others have nearly closed to merchandise for several seasons.

Koweit, at the head of the Gulf, owes its importance to the fact that it offers the only possible site for an enclosed harbour, and at Kathama, a hamlet at the extreme western end, the Germans hoped to station the terminus of the Baghdad Railway. Not the least of the settlements due to this war will possibly be the abandonment of Koweit for this purpose. A large amount of costly dredging would be necessary before ocean-going liners could approach even Ras-ul-Arz at the south-eastern horn of the bay of Koweit, where the water is deepest. The dredging of the mouth of the Shatt-ul-Arab, which at present admits only steamers drawing 17 ft. of water, though a laborious and continuous task, would be a better plan, especially as the construction of the line from Mohammera to Khoramabad will one day double the importance of the navigation of the Shatt-ul-Arab. You cannot, of course, connect Mohammera directly with Koweit.

VII.

Leaving the friendly shores of Sheik Mubarak, we soon reach through tortuous under-water channels the mouth of the Shatt-ul-Arab. On the left is Fao, which, you will remember, was taken by us without much resistance on November 6th last. It is a place of which the importance lies at present in the fact that it is the landing-place of the submarine cable to India. Just as Lingah may stand for most Gulf ports, Fao may be taken as a sample of the kind of settlement that here and there breaks the continual line of Shatt-ul-Arabian date palms. These palms, which make of the Shatt-ul-Arab an important producing district even apart from its value as a clearing-house, for the most part grow on both sides of the river to a distance varying between one and four miles. The eastern shore, that is to say, that on the right as one goes up, is the bank of Abadan Island, where the fringe of palms is, however, not continuous, and after a journey of about thirty miles the buildings of the refinery of the Anglo-Persian Oil Company are seen, breaking the flat monotony of the horizon. This is the terminus of the famous oil pipe-line which leads the precious black liquid down from the fields at Maidan-i-Naftun, 140 miles away. To that I shall refer later.

A few miles further up the River Karun comes in from the east by a channel known as Hafarieh, or "the excavated place." It may, indeed, be an artificial construction, as the name implies, though it is difficult to imagine why this enormous and unnecessary cost should have been undertaken by anyone. Alexander the Great, who is sometimes credited with the work, was certainly not fool enough to waste months and men on such a work when the Bahmishir was navigable. Mohammera, at the junction of the two rivers, is of course on Persian territory. It will probably leap into importance as the terminus of the railway through Khoramabad,

which will one day communicate, through Hamadan and Kasvin, with the European railway system.

There is one thing I should like to say of Mohammera. A most significant contrast was a few years ago to be seen here. There are two warehouses and distributing centres for goods. One is that of Messrs. Lynch, which, large as it is, was on the day of my visit piled to the roof. The other is the roofless compound of the Germans. This was not merely entirely empty of goods, but was overgrown with weeds and nettles to a height of 3 or 4 ft., except around the broken gateway, where the daily deposit of much of the town's refuse checked the vegetation. Yet it is on the strength of that compound as much as anything else that the Germans dared claim commercial interests on the Karun.

Twenty-two miles up the Shatt-ul-Arab lies Basra. The interminable lines of date palm are broken on the right at Fahlie, where is the palace of Sheik Khazal of Mohammera. There is a pretty little custom observed here. Once upon a time the Sheik was able to render a British-India boat a service against some river pirates. From that day no British-India boat steams up or down this stretch of the river without firing a gun of grateful memory opposite the large and somewhat Italian-looking palace of the Sheik.

VIII.

Basra is a generic term for the old town four or five miles inland, for the deserted ruins eight miles further to the south-west, and for the modern quarter near the river. The most striking view of the place is that along the bank of the Ashar Creek, where the occupation of the place was proclaimed on November 23rd last by Sir Percy Cox and General Barrett. I do not need in this company to expatiate upon the great and notable service that Sir Percy Cox has rendered in the Gulf.

As will be seen, Basra is not a place of great architectural dignity. The Consulate is the only building of importance, an imposing square structure deeply verandahed and approached by a double flight of stairs. The bank of the Ashar Creek is lined with hotels and merchants' houses. It enjoys no reputation for unusual propriety. The bazaar is not very different from any other of the smaller Oriental bazaars. One may buy there ghi and grindstones, dates and dal, sweets and shampooing stones from Bahrein, cotton goods, coffee, red sugar, tobacco, and fish. You may choose also from an indiscriminate medley of cheap German and English hardware. The most remarkable building in the native quarters is the Minaret Bashayyan, which presides in a suit of brand-new blue tiles over a two-hundred-year-old mosque. Otherwise, date groves intersected by creeks and channels form the only feature of inland Basra.

Four or five miles higher up the Shatt-ul-Arab is Magil, the site of the old East India Company's post, now used as a military camp. At Magil the Euphrates falls into the Tigris. This is a fact which has only recently been known, and it has become known through the surveys conducted by Sir William Willcocks. I am sure that you will let me express the deep gratitude which everyone who has had any connection whatever with Mesopotamia must feel towards Sir William Willcocks. We may or may not agree with his identifications of the site of the Garden of Eden, but his activities in this district have not only drawn the attention of the world to the vast and wasted industrial opportunities of Mesopotamia, but have provided a foundation upon which all recent work in the district has been based, whether it be concerned with irrigation, railway construction, navigation, archæology, ethnology, or politics.

Sir William was the man who discovered that every atlas in the world was wrong, and that the Euphrates does not flow into the Tigris at Kurna. That passage is now a stagnant marsh. Magil is the actual point of junction, and was a base for much of the German railway material.

Beyond Kurna the groves of date palms cease for a time, and a flat and dreary expanse stretches away on both sides of the river. I shall take the liberty of quoting a short description written during the expedition to Mohammera of 1857 and kindly put at my disposal by Sir George Birdwood. It is as true to this day as a picture of the alluvial flats which constitute the whole of the delta of the Tigris and Euphrates. On the Shatt-ul-Arab itself this waste is, indeed, hidden by the fringe of date palms, but behind them it exists without a break or change, except such as greater or less swamp presents, from Amara, Ahwaz, and Nasrie on the Euphrates to the Persian Gulf.

"It is entirely fenny, and one can see nothing for miles but submerged lawns and bulrushes and other sedges, among which immense flocks of wild geese, pelican, and duck pasture. Higher up the river the banks are somewhat more raised, and are fringed with date groves, alternating with barren tracts of camel thorn and stubbly grass, the scanty eatage of the beasts of the villages."

Sir George Birdwood notes also that liquorice grows here. Here and there huge thickets of tall bamboo grass afford shelter to wild pig and a few buffaloes. It is not so long since lions were to be found here, but, if they still exist, they have now been driven far afield, and there seems no recent record of one having been shot. Besides this, tamarisks, willows, and hard scrub are the only plants that break the flatness of the plain.

The one building that breaks this dreary outlook until the town of Amara is reached is the sapphire-tiled tomb of Ezra. This consists of a domed building surrounded by a caravanserai for the reception of pilgrims. After that there is little to attract the eye until the famous 75-foot arch of the palace of Ctesiphon breaks the horizon a half-day journey from Baghdad itself.

Before leaving the immediate vicinity of the Shatt-ul-Arab, the strange sect of the Sabæans must be mentioned. Probably they draw their origin from Zoroastrianism; it is not unlikely that they tinged Mohammedanism with part, at least, of the Unitarianism of the great Arabian creed. It is clear that they draw much of their dogma from the Jews and a little from the Christians. It is owing to this elasticity that they still exist. A church—if the word may be used of a community that is at least consistent in refusing to build any place of worship except of wattles and mud—that can survive in the very centre of the many jarring sects of the Shatt-ul-Arab is worth a passing notice. At present they are conspicuous as a remnant that preserves a secret and most beautiful method of niello work, and worships indifferently St. John the Baptist and the Pole Star.

IX.

The climate of this part of the world deserves criticism. It is open to it, and, to be just, it has always received it. I cannot refrain from quoting to you an Oriental account of the temperature of Muskat. There is no doubt that Muskat is terribly hot, and hot with a wet heat that has an element of terror in it; but the place scarcely deserves this: "The heat," says Abd-er-Rasak, "was so intense that it burned the marrow in the bones.' The sword in its scabbard melted like wax, and the gems that adorned the handle of a dagger were reduced to coal. In the plains the chase became a matter of perfect ease, for the desert was full of roasted gazelles." But in plain truth, Muskat's heat has exacted a heavy toll of Europeans. A place which has known a sun-temperature of 189° F. is not a health resort.

Basra in summer is terribly hot. At the Maidan-i-Naftun, Europeans are compelled to become troglodytes in the summer mid-days. Through August, 1908, the highest shade temperature of the day was often 126°. In London I remember half a panic, because 97° had been reported. Still, if the heat is a dry heat there is almost no limit to human endurance of it, and the man in the East takes no liberties with the sun, and digs himself a "serdab" wherever he finds the natives fleeing underground in summer. In the Shatt-ul-Arab in winter there is often a touch of sharpness in the night, though there is never an actual frost; and there is no impossibility about making a hot weather station among the Bakhtiari Hills, some of which remain snow-capped even in August.

For the rest, Ahwaz is a martyr to "habubs," and the desert wastes of Mesopotamia can provide sandstorms which the Sahara can with difficulty rival. I may perhaps be allowed to show you a curious photograph. The approach of these sandstorms is heralded by a huge canopy of lighter sand, which obscures the sun and warns the traveller of the coming tornado of heavier grit and stones. The photograph which I show you was taken by me just before the storm along the ground struck me. The River Euphrates, a tree, and the silhouette of some village huts can be seen. The darkness during the passing of the storm is greater than that of a total eclipse. Still, life in Mesopotamia and the Shatt-ul-Arab is quite bearable for white men. Worse, perhaps, than the heat are the mosquitoes; and worse than the mosquitoes are the flies.

X.

The approach to the Shatt-ul-Arab from the east lies through the Bakhtiari Mountains. For several years the route has been dangerous, and only the explicit favour of the Ilkhani of the Bakhtiaris will make the journey safe. The beauty of the route is extraordinary, and the archæological remains at Malamir no doubt tempt an occasional visitor to risk the journey from Ahwaz; but the roughness of the tracks—there are no roads—through the mountains is very great, even if one cannot wholly endorse the reference to them in the Sahangusha. "If the pen of description wished to give an idea of the route, so steep and so difficult, it would be lost in the forest of astonishment, and

confounded in the desert of feebleness." I should not, however, have said that there is no road. Here and there one comes across a section of a very ancient road, nothing less than the Ra-i-Sultani, which once led from Persepolis to Susa. But when one comes to a section of this road it is better to get off one's mount and lead him beside it, even if to do so necessitates a dangerous excursion on the edge of a cliff. The photograph will explain what I mean.

The story of the Anglo-Persian oilfield, which lies not far from this remote highway, is one of the great romances of commerce. The original concession was given to Mr. D'Arcy, and hundreds of thousands of pounds were sunk by him at Chiah Surkh, Ram Hormuz, and at last (on the suggestion of M. de Morgan, the excavator of Susa) at Maidan-i-Naftun, roughly thirty miles east of Shustar. At last, at a depth of 1,200 ft., oil was found here, and in March, 1908, a huge jet of black liquid burst through the well, flung the derrick aside and mounted 70 ft. into the air. I was at the oilfields five or six months afterwards, and these photographs may have some interest for those of us who like to have some record of the early stages of an industry that is likely to revolutionise this district in the East.

From the oilfields it is a long day's journey into Shustar, which I found in the throes of civil warfare. I had an order on the acting governor for an escort to Shalilieh, the steamboat terminus on the river, but from the depths of his serdab His Excellency refused it, saying that his men would be ambushed and killed on the way back. It would be all right, he said, if I went through the town openly, as they had no quarrel with Englishmen.

From Shustar one used to paddle down stream in the "Shushan," a hind-wheeler originally built for the relief of Gordon in Khartoum. The other little steamer, which incurred Lord Curzon's comments—they are still remembered by the engineer—has long been at the bottom of the river. Through Ahwaz—where in old days the climate was said to make men lose their wits very soon and certainly—one floats in a ballam down stream to Mohammera, between the bare desert banks which have been described. I arrived on the opening day of the date season in 1908, and ate some. I cannot understand Palgrave when he asserted that satiety did not attend the eating of the date in its own country. I know that I had four of these warm, golden, translucent bags of honey, and I would not eat another date for a year.

XI.

Down the Euphrates there can scarcely be said to be a way at all. In the end of 1911 a venturesome captain took one of Messrs. Lynch's smaller steamers up the river, but though he was a picked man, specially chosen for the work and well known to Arab tribes, he found the difficulties caused not only by the navigation, but by the hostility of the Arabs, so great that it seems improbable that a paying line of communication can as yet be established between Basra and Feluja.

In this connection I may mention, without discussing it, that Willcocks' magnificent scheme of irrigation has, as usual, a reverse side. So wonderfully utilised will the waters of the two rivers be that it is not impossible that navigation during the autumn and winter months may be seriously impeded. Sir William Willcocks is reported to have grimly remarked that his business was irrigation and not navigation. The parallel of Cairo might be adduced. It is not likely that even a full realisation of this great scheme will greatly affect water connections between Baghdad and Basra, except possibly between November and February.

XII.

There remain to be briefly noted three or four matters. The first is the probable effect upon the Turkish Caliphate of our presence in Southern Mesopotamia. The Arabs are no friends of the Turks, and the recent action of Gadban, chief of the Beni Lam tribe round Amara, has been, perhaps, dictated by financial considerations. One thing is clear. Our presence at Basra will do more to encourage our friend, Ibn Saud, the reformer of Arabia, than ten thousand men in the field. An ardent Mohammedan, he knows our traditional respect for the religious feelings of others, and he remembers the proclamation that we issued early in the war to the effect that the Holy Places of Islam would not only be respected, but, so far as possible, protected by us.

The second is the Baghdad Railway. I have no time in which to remind my hearers of the birth of this ambitious project. The German scheme, insh' Allah, has become impossible. There remains, however, much for the Russians, the French, and ourselves to consider as to the carrying through, or partial carrying through, of this plan of linking up Europe with India.

The line of the lower part of it may be traced on the map. Herr Meissner, before journeying westwards to organise the Sinaitic railway, which is relied upon for purposes

of Egyptian invasion, threw hundreds of tons of brand-new railway material into the Tigris, in the hope of blocking the advance of the English. I trust it may be recovered, as, from personal observation, as well as from a curious admission to me by Baron Marshall von Bieberstein in 1912, the plant is of first-rate quality—so good that the German promoters grumbled at the expense. The London and North-Western would not refuse it. As a means of connecting the West with the East the scheme may be postponed. But it cannot be wholly abandoned, and it may be news to some that it is actually in full working order between Raju and Aleppo, Aleppo and Ros-el-Ain, and Samara and Baghdad. From a military point of view these distances of rail are not without importance. From a diplomatic point of view the hiatus is more interesting than the completed line.

The Kurds round Mosul said in 1911 that they did not want the railway, and these mountain Medes have a way of making their prejudices respected. The three gaps in the Baghdad Railway are due, first, to the mountain barriers of the Taurus and of the heights near Suleimanieh; secondly, to the hostility of the Kurds near Mosul; and, thirdly, to the manner of the resolute attitude taken up by England in regard to the southernmost section of the line. I remember well that at a time when the continuation of the track to Basra was supposed to be entirely a matter of arrangement between the two western countries, Marshall von Bieberstein, correcting a statement of mine that Aleppo was a terminus of the line—which in a sense it is—said quickly, "The terminus of our line is not Aleppo. It is Basra."

Something will have to be done with what we may already call our section of the line, if only to utilise the great work of Mesopotamian irrigation.

The third and by far the most important matter is our English responsibility for the administration of these vast alluvial flats. I have no wish to dogmatise on the question. But three points become increasingly clear: (1) We have no right to abandon them without seeing that some form of what Lord Hardinge calls "benign administration" is secured for them; (2) we cannot allow them to return to the administration of Constantinople or of Konia; (3) we have to protect much more than our own material interests. Prestige is a vague and sometimes a misused word; and at this moment I will not use it. But if we wish to protect India, we must protect the gates of India. And if—as I hold—the Shatt-ul-Arab is one of the outer gates of India, we must hold the Shatt-ul-Arab and as much of the land behind it as may be necessary for that purpose. If we do that, we may let the question of our prestige rest for the next half century.

In any case, the completion of the southern reach of the Baghdad-Basra line and the carrying out of the huge projects of Sir William Willcocks, whether by us or with our good will, will lay upon us burdens of watchfulness and preparation, and an eternal possibility of the need for intervention. What will eventually be done lies on the knees of the gods. It is only our immediate task to see that what is certainly the greatest work of administration that man has ever achieved for his fellow man, our government of India, shall not be threatened because, when the day came in which we could have made it secure, we failed through craven fear of being great.

DISCUSSION.

THE CHAIRMAN (the Right Hon. Earl Curzon of Kedleston, G.C.S.I., G.C.I.E.), in opening the discussion, said he thought Mr. Landon had justified the prediction which he had made in his opening remarks, in so far as he had within the space of an hour dealt succinctly and picturesquely with the history, geography and the political status of Basra, the Shatt-ul-Arab and the neighbourhood; indeed, he had cast his net over a rather wider ocean, because he had taken the audience down to Muskat, at one end of the Persian Gulf, up to the Barrage on the Euphrates in another direction, and to the town of Shustar and the oil wells in the Bakhtiari country more to the east. He (the Chairman) was not going to follow Mr. Landon into any of those areas. It was now more than twenty-five years since he had had the pleasure of visiting those countries, and it was with genuine enjoyment and emotion that he recognised sites, once so familiar to him, on the map, and that he saw photographs of places shown upon the screen, every one of which he had seen, with the exception of the Euphrates Barrage, Babylon (which, at the time he was there, was buried underground in great indurated piles of clay and mud), and the oilfields in the neighbourhood of the Karun River, which were only discovered at a later date. He passed all that by for the moment, because the region which Mr. Landon had been describing had an entirely new interest from the events of the past few weeks, to which he proposed to devote a few observations. It had a new interest, because it had become a minor theatre of the

great war in which we were engaged, and of which there was a reminder in the papers only that very morning in the account of the rather heavy fighting which had taken place, apparently within the last few days, in the countries which formed the subject of the paper. He had said "minor theatre of war," but he should be very sorry indeed if anyone were to draw from his employment of that phrase the conclusion that any soldier, be he officer or private, who was fighting, and who very likely, as had happened in several cases, had laid down his life for his country in that territory, was rendering any minor service to the country than those who were engaged in what were popularly regarded as the major scenes of operation in the trenches of Flanders and France—from which, he might say in passing, he returned only the day before—or even in the operation of forcing the Dardanelles. He preferred the poet's old maxim :—

> "Give all thou canst : high Heaven rejects the lore
> Of nicely-calculated less or more."

Every man who was fighting and running risks in the Gulf, in East Africa, in the Cameroons, in Nyasaland, or in the recent riot at Singapore, deserved just as much to be in the eyes, and to receive the gratitude, of his fellow-countrymen as those about whom we were reading daily, and who perhaps only a week or two ago were undergoing that storm of hellfire in the neighbourhood of Neuve Chapelle. Those brave men of whom he spoke did not need advertisement, still less did they ask for it, but it was our duty to give it to them. He had had letters from many of them from different parts of the world, and it could scarcely be imagined what encouragement was given to them in their remote and unfriended stations by merely a mention in Parliament, or by a letter in the newspapers, showing that we at home knew what was going on. Therefore most gladly did he welcome the opportunity of saying a word of recognition of the splendid service which was being rendered by our Indian and other troops in that part of the world. The section of the war line of which he was speaking was of great importance to this country and to India for more reasons than one. In the first place, we were fighting there our enemies the Turks, and we were dealing what he hoped would be a useful blow against a people who had plunged into war with us without the faintest provocation as the result of a perfidious and nefarious intrigue—a people whom we had consistently befriended for years, but with whom, he hoped, we should have no friendly truck for many a long day to come. We were occupying their troops in that part of the world, and incidentally he hoped we were engaged in the process of lifting a hand from those regions which any who had listened to the author would have realised had had a blighting effect for centuries. Secondly, we were carrying out our traditional policy in the Gulf about which so much had been said. There was a new and interesting aspect of the situation in the foundation of that great oil interest to which Mr. Landon had referred, and upon which so many millions of money had been spent with such hopeful prospects of success. Again, a novel interest arose for us from the fact that, as the upshot of these proceedings, it would be our duty to create for those parts of the world a future which should be in consonance with their great and prosperous past, that should give a chance to the people of the country themselves, and incidentally would add to the security of one of the gateways of the Indian Empire. He had spoken about our traditional position in the Gulf. He need not attempt to define it, because that had been done in the admirably clear language of Mr. Landon in his paper, who rightly pointed out that this position had been created by a century of devoted and unsparing effort on the part of Englishmen, consecrated by no small expenditure of treasure and of life. The rights which had thereby been created were, he was glad to say, of universal recognition. Many years ago, when he was a traveller in those parts, he wrote in a private capacity strong words about our position in the Persian Gulf. He had been allowed to publish those words by his late chief, Lord Salisbury, when a few months later he became Under-Secretary for India. It might be taken, therefore, that they represented Lord Salisbury's views and his policy at the time. At a little later date they were endorsed and repeated by one much more influential than himself, namely, by Lord Lansdowne, who was Minister for Foreign Affairs. They had been ratified by subsequent Foreign Ministers, and he had no doubt nothing had been said at that time on the subject which would not be endorsed by Sir Edward Grey to-day. The present war had afforded us an opportunity of placing our policy at the head of the Persian Gulf on a stable and solid basis, which might be expected to give us peace for at least a century. The author had spoken cautiously about the future. He thought Mr. Landon was right and wise to adopt that tone, and he would emulate his example. It was not, he thought, a very good practice to set about discussing the ultimate distribution of territories of which we were not yet in complete possession, and while the war, which was intended to enable us to occupy them, was still in progress. It seemed to him almost as futile a process as that of discussing terms of peace—an attitude to which many of his fellow-countrymen seemed most unaccountably and, as he thought, unwisely prone—before peace was even on the horizon. It must be remembered, after all, that, whatever might be our individual

views or aspirations, peace would not be concluded by us alone. It would be concluded by those who were fighting along with us round a conference table at which the interests, views and desires of all the parties must be discussed in relation to each other, and the issue of those proceedings would be determined by a number of considerations not relating to or representing the views of one party alone. But when that time did come he had not a doubt of one thing—and it ought to be the object of those who had served in India or who were interested in India to see it was so—that at that conference table India, in relation to those parts of the world which had been under discussion that afternoon (just as our dominions across the seas in relation to other parts), should have her place, and that her voice should be heard. Although he thought at present it was wise to speak with great caution about the future, there were certain propositions which might without risk be laid down. The first was that the region which had been under notice that afternoon could not be left in the future to the inept and futile administration of the Turks. Perhaps people in this country hardly realised that it was no natural possession of the Turks; they were interlopers in the country. The inhabitants of the land were Arabs; the Turks were merely a governing and military caste in the towns. The part which was to be played by the Arabs in the future was a much more important question than the part to be played by the Turks. Hitherto we had had most friendly relations with the Arabs, and he endorsed what Mr. Landon had said about the terms on which we had been in recent years with the Sheik Mubarak of Koweit, who had been absolutely loyal and firm in the present crisis, and with others whom he might name. It was a puzzle to him why in the earlier stages of the fighting the Arabs appeared to have sided with the Turks. He did not know enough of the inner history to explain why that was so, but it certainly should be the object of our diplomacy to detach them from the side of the Turks and to resume those pleasant relations with them which had characterised our policy during the last fifty years. His next proposition would be that those regions had immense potentialities both for irrigation, for increase of population, and for wealth of almost every description in the future. He concurred with the author in his remark that Basra was the natural emporium of that part of the world. Usually when for something like a thousand years or more a place had been the centre of a great and flourishing trade there were conditions, geographical, physical and otherwise, which explained its predominance. Those conditions had been clearly brought out in the paper. They would ensure, he believed, a position for Basra in the future as great as it occupied many centuries ago, and he looked forward to the time when Mr. Landon's prophecy would be fulfilled, and when it would again be one of the great and prosperous mercantile cities of the East. There was one other proposition. We could not allow those areas to be the scene again of the political intrigues which they had witnessed during the last ten or fifteen years—intrigues conducted by Powers admittedly hostile to ourselves. He was not going at great length into that matter, but it should be enough for us to say that there must be an end once and for all to all German influence in those regions. The Germans could not be allowed to have any part in the future development of Lower Mesopotamia. He did not think the Turks would have very much part, but the Germans must have none. The Baghdad Railway, designed and carried out for political even more than for economic reasons by the Germans, would no doubt be constructed in the future: but he hoped it would have a different character and a different aim, and he trusted that with such control as we might possess over it, it might be directed not for the advancement of political intrigues, but for the furtherance of the interests of the country itself. More he would not say; the question was very difficult and very complex, and any man who pronounced too definitely upon it now might have reason to rue his rashness later on. For the moment it seemed to him that all we had to do was to see that our troops, who were braving the dangers of desert warfare in an exposed position, and who would shortly be subjected to the extremely exhausting heat of the Mesopotamian summer, should be reinforced by the Indian Government and placed in a position where they could not only hold their own, as they were at present doing, but, if the necessity arose, should be able to push forward their advance. We might be glad that they were led by, and that diplomatic proceedings were in the hands of, such good men. Sir Arthur Barrett, the General in command, was one of the finest soldiers whom the Indian Army had produced in recent years. We might be safe in knowing that our diplomacy was in the hands of Sir Percy Cox, our present Resident on the Persian Gulf and one of the best Political Officers by whom it had been his (the Chairman's) privilege to be served. The administration at Basra was in the hands of Mr. Dobbs, of whom he thought he could truthfully say that he had been trained by himself while he was in India. He desired to add one word in passing of profound and sincere and sorrowing sympathy with regard to Captain Shakespear. Could anything more melancholy be imagined than that this brave and heroic man, who had acquired an ascendency over Arab tribes almost unique, should lose his life in a petty scuffle between native tribes in

whom he had nothing but the most remote interest, and in which he was probably taking part owing to a chivalrous regard for the chief to whom he was attached? It was one of those pitiable happenings which occurred in the world's history, and all that could be done was to deplore his loss and to deposit a mourning wreath upon his grave. In conclusion, there was one thing to be borne in mind. Let them give their support to the Indian Government, and to the Government at home, in endeavouring to secure for those regions, when the war was over, a future that should, on the one hand, further our Imperial interests, render safer than at present the approaches to India, and, even more than that, should take into account the interests of the populations of the country in question.

Sir Hugh S. Barnes, K.C.S.I., K.C.V.O., said it was hardly necessary for him to say much about the subject of the paper after the remarks that had fallen from the Chairman. He agreed that they had listened to a most interesting and instructive paper, well worthy of Mr. Landon's reputation and high quality as an author and journalist. Mr. Landon had enriched his recollections of what he had seen and heard with a wealth of historical detail and an appreciation of the political problems awaiting decision, which had added greatly to the value of his paper; and when this was supplemented by the illuminating and inspiriting speech they had heard from Lord Curzon, he thought they might all congratulate themselves that they were fortunate enough to be present there that afternoon. He had had the privilege of listening to Lord Curzon many times in India and in England, and had always found his speeches in the highest degree invigorating and a healthy tonic against depressed and pessimistic views. He thought they would agree that the speech they had just heard fully came up to that description. There were three points which he would like to mention. The operations which were at present going on in the Persian Gulf should not by any means be made light of. If he, as a spectator, looking on the matter as an outsider, but with some knowledge of the East, were to make any criticism, he would be inclined to say that possibly the Government of India hitherto had rather been prone to make too light of the operations which they had undertaken in that they had not sent sufficient troops at the outset. He believed those troops had since been very largely reinforced, but it was of the utmost importance that it should be remembered that in the operations at Basra the Indian Army were no longer fighting the comparatively untrained troops of Afghanistan or the tribesmen of the North-West Frontier, but were meeting highly organised and trained soldiers, composing practically a European army—men belonging to the races who not so very long ago held the Russians at bay for two months at Plevna, and who recently had gone through the lessons of the great Balkan War. It was of the utmost importance that the operations in the Persian Gulf should be treated in a big way, and that on no account should they be permitted to fail. The success of our arms there was of the utmost political importance for this reason, that there was no doubt that any reverse or mismanagement, in the present high state of tension in the Mohammedan world, might have incalculable results, not only in the Gulf, but also in countries further to the east. Another point was the cynical disregard of Persian neutrality which had been displayed by the Turks and their German preceptors during the course of the war. It would have been gathered from the telegram that had been received that very morning, and from looking at the map, that one of the attacks which had been made upon our troops was at Ahwaz, and that Ahwaz was in Persian territory. It might well be asked why, if Persia was a neutral country, it happened that our troops were there, and that the Turks were attacking them inside the Persian frontier? He did not so much blame the Turks for that. He had lived so long amongst Mohammedans in the North-West Frontier that he had very sincere sympathy with the elder Turks in the plight in which they found themselves landed by the intrigues of the Germanic Powers. The elder Turks might possibly, if we were engaged with them alone, have been trusted to play the game, but we had seen in the West how utterly Germany was inclined to disregard the rights of neutrals when they appeared to conflict with her military advantage, and Turkey had obviously been led by her ally to take the same view of matters in the East. No sooner had the war broken out than the Turks attacked Tabriz in Northern Persia. They were compelled to retreat from there by the Russians, but it had recently been learned that they were again advancing across the border towards Kermanshah. After our occupation of Basra, finding they could make no impression upon our troops on the river, they crossed the border and advanced upon Ahwaz, and it was in that advance that the action occurred, not so very long ago, in which the Seventh and Fourth Rajputs were engaged and in which we lost several officers. That was a direct violation of Persian neutrality. He supposed at some time or another we should hear of the Germans, as usual, reversing cause and effect, and saying that they had invaded Persian neutrality because we had violated it first. But during our advance up the Shatt-ul-Arab Persian neutrality had been thoroughly respected. Not a soldier had been landed on Persian soil until it was threatened by the Turkish armies,

Thirdly, with regard to the German intrigues in Persia, which had been alluded to by Lord Curzon, those intrigues had been well described in that number of the *Times* "History of the War" to which Mr. Landon had drawn attention, and which was a most accurate and complete summary of the rise of our power in the Persian Gulf, and of the attempts which had been made during the last ten years by Germany to undermine it. Those intrigues of Germany had not yet ceased. It was only on February 16th that Herr Wasmuss, the German ex-Consul at Shiraz, arrived in Dizful from across the German frontier from Baghdad, accompanied by the Baghdad agent of Messrs. Wankhaus, who had been the unofficial agents of the German Government for the past ten or fifteen years in the Gulf. They arrived at Dizful with a following of border chiefs. They went on to Shustar, they paraded the bazaar in Persian costume, they sent for all the mullahs, they spent money freely, and distributed leaflets calling on the Persians to join in the Holy War. They then went on through the edge of the Bakhtiari country to Shiraz. The recent *communiqué* of the India Office would also be remembered, which gave an account of the papers which were discovered among the archives of the German Vice-Consul at Ahwaz. He had also seen a letter from Bushire to the effect that Dr. Listermann, the German Consul at that place, had been lately arrested and that papers of his had been found showing he was engaged in stirring up the Persian tribesmen to attack Bushire and destroy all the English residents. It was also known that they had stopped wheat exports from Bushire by the expenditure of money among the Kashgai and other tribesmen, and it had even been said that they had to some extent succeeded in tampering with the loyalty of the gendarmerie under the Swedish officers. All those things fully entitled ourselves and the Russians to take any action we thought justified to support the Persian Government in their resistance to all intrigues of that kind. In one respect he felt inclined to say that we ought to take a leaf out of the German book. Nobody wished that our officers should indulge in the intrigues and falsehoods which had characterised the German manœuvres in those parts, but there was one way in which he thought we might follow their example, and that was by freely expending money among the border tribesmen. He had been a frontier officer in India, and had a good deal of experience of frontier tribes, and among impoverished people like the Arabs in the neighbourhood of Mohammera and Shustar, and also on the Turkish side of the border, money was a great power. In his opinion we could not afford to allow the Germans to tamper with the loyalty of those men by a free expenditure of money without attempting to do something in the same way. He was quite confident that if our Government would put £100,000 at the disposal of Sir Percy Cox, a mere drop in the ocean of our vast expenditure, with instructions to subsidise and employ the Arabs who were now, owing to German intrigues, giving so much trouble in the rear of our troops at Ahwaz and elsewhere in that region, not only should we relieve our officers of a very serious addition to the responsibilities which they had to face, but in all probability we should also succeed in saving very large sums of money and probably a good many valuable lives.

Sir Joseph Walton, Bt., M.P., said he might mention that it was in response to a suggestion of the Chairman that a few years ago he made a journey through Persia, covering practically the whole of the territory mentioned by Mr. Landon. That journey had enabled him to raise, in the House of Commons, the whole question of the Persian Gulf and our predominant interests therein, and he was glad to be able to say that it was no political party question. His resolution on the subject in the House of Commons had been seconded from the opposite side by the late lamented Under-Secretary for Foreign Affairs, Lord Percy, and it received from the Government an emphatic declaration of policy on the lines indicated by Lord Curzon. As the Chairman had stated in his speech, we had somewhat neglected our interests on the Persian Gulf in recent years, but we had a new opportunity to-day in consequence of the war to reconsider our position in those regions, and he rejoiced to know that in Lord Curzon we had a statesman whose powerful advocacy would be available, when the time of arranging terms of peace arrived, in taking care that our interests in India and in that part of the world were properly safeguarded. He would venture to say that those same views would, if occasion arose, be also voiced in the House of Commons by men of all parties, because it had become increasingly recognised that properly to safeguard India we must at any rate have a controlling influence in the lower part of the Baghdad Railway, from Baghdad down to some point at or near th Persian Gulf.

Colonel Sir Thomas H. Holdich, K.C.M.G., K.C.I.E., C.B., D.Sc., said he thought the Society might congratulate itself on having departed somewhat from its traditions in the matter of discussion. After the eloquent speeches which had already been heard connected both with the war and politics, he desired only to say a word or two. First, he wished most sincerely to echo the sympathetic words spoken by Mr. Landon on the subject of the death of Captain Shakespear. Then Mr. Landon had referred to gun-running in the Persian Gulf. There was something very peculiar about the process of

gun-running, and to his mind it illustrated in a very remarkable way the principles of free trade. If he was not mistaken, the guns which were so "run" were manufactured in the first instance in this country. It was a British trade. The guns were conveyed up the Persian Gulf in British ships; they were then carried from the Persian Gulf to the tribes on the Indian Frontier by Afghan caravans, and were sold to those Frontier tribes. How did those Frontier tribes pay for them? He believed they were paid for by money which we ourselves gave to them in order to keep them quiet! He desired to congratulate Mr. Landon on his paper, which both in manner and in matter very nearly reached the best ideal of what a paper of the sort should be.

The Right Hon. Lord Reay, K.T., G.C.S.I., G.C.I.E., in moving a vote of thanks to the author for his paper, said very seldom was it that a reader of a paper was so well equipped for his task as Mr. Landon. This country owed a debt to those who unofficially took the initiative in their travels to do what officials could not always do. Perhaps there was no field in the theatre of war where British interests were more directly at stake than the operations which were at present going on in the Persian Gulf. One thing which should not be forgotten was the valour of the Indian troops and the humane and chivalrous way in which they behaved—which was more than could be said for our enemies. In hearing the list of articles conveyed by the ship mentioned by Mr. Landon he wondered whether they would have been considered as absolute or conditional contraband by the Germans. In conclusion, Lord Reay, on behalf of the Committee of the Indian Section, thanked Lord Curzon for presiding. He had given, as he always did, a most exhaustive survey of the questions which were at stake. He (Lord Reay) entirely agreed with the Chairman that it behoved us to be extraordinarily careful in the way in which we discussed the terms of peace.

Sir John Jardine, M.P., K.C.I.E., in seconding the motion, said he was glad previous speakers had mentioned Captain Shakespear's name in terms of full appreciation and great knowledge.

The vote of thanks was then put and carried, to which Mr. Landon briefly returned thanks, and the meeting terminated.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 21st, 1915; The Right Hon. Walter Hume Long, LL.D., F.R.S., M.P., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Baw, U. Kan, K.I.H., Pyinmana, Yamathin District, Burma.

Bright, Charles, F.R.S.E., M.Inst.C.E., M.Inst. E.E., Members' Mansions, Victoria-street, S.W.; and The Grange, Leigh, Kent.

Griffin, Louis T., The Auckland Museum, Auckland, New Zealand.

Humphrys, Claude William Erskine, Penang Rubber Estates Co., Ltd., Province Wellesley, Penang, Straits Settlements.

The following candidates were balloted for and duly elected Fellows of the Society:—

MacCaw, Vivian Hardy, 21, Strand-road, Calcutta, India.

Pardiwalla, Jehangir Pestonjee, Hotel Majestic, Bombay, India.

Saunders, Alfred Oliver, 25, Newport-road, Moseley, Birmingham.

Spence, Charles Stewart Traill, Plantation Waterloo, Nickerie, Surinam, Dutch Guiana.

The Chairman, in introducing the lecturer, said the subject was especially interesting at the present moment, because, while everybody was thinking out the problems connected with the present war, the time was also being looked forward to when—the war having been terminated in the only way which citizens of the British Empire contemplated as possible—it would be necessary to make provision for those who had taken part in it. Doubtless many of the soldiers and sailors who were doing such gallant deeds for their country on sea and land would not be able to return to their original vocations, and many of those who were physically able would not be inclined to return to the narrower and more limited possibilities of life in the old land. And just as the war was being fought by the whole British Empire, just as it was realised that in the immediate future participation in the consideration and settlement of Imperial questions by our oversea dominions was a necessary consequence not only of the war but of all the great events which had preceded it in our history as an Empire, so it was felt that the dominions would take their part in offering facilities and opportunities to our soldiers and sailors to find new openings for themselves in distant parts of the Empire. It must, he thought, be true that great openings would be found in connection with the fishing industries on the two coasts of the Dominion of Canada, and no doubt in other parts of the dominions all over the world. He could not help thinking that there was an immense industry to be created and developed in connection, especially, with sea fisheries. He believed that in Canada on both its coasts there were great potentialities, great sources of wealth, great possibilities of industry, and at the same

time the climatic and other conditions were such as to make life in that country agreeable. Consequently it must be specially interesting to hear one, who would speak with great authority acquired by personal investigation and knowledge, upon such an extremely engrossing subject. He (the Chairman) believed we were only just beginning to realise what were the opportunities offered to us as an Empire, how vast were our possessions, how great were the fields open; and while, in common with everybody else, he profoundly regretted that the war had been forced upon us, the loss of dear and valuable lives, and the heaviness of the burden which had been cast upon this country, he yet believed that to that cloud—black, dark, and heavy though it was—there was a silver lining to be found in the new birth of the British Empire, with immense possibilities before us, with a great strengthening of the bonds that bound us, and with the realisation of the fact that the Empire in future would be one in reality and not only in name, and that all parts of it would be bound together so that we should make the best possible use of it; and he believed the end of the war would see the British Empire able to maintain itself, to defend itself, and to hand down to generations yet unborn a heritage even greater, more priceless, more real than that great one which we had received from our predecessors.

THE AUTHOR prefaced his paper by saying that the fisheries of this country, only a few years ago, had been neglected by the Board of Trade in an extraordinary manner. After some moderate agitation on the part of the few who were interested, the fisheries were handed over to the Board of Agriculture, and if the Chairman had remained a short period longer at the Board of Agriculture, he would have been in charge of that immensely important industry. He (the author) hoped, by effluxion of time, the fisheries would be got out of the Board of Agriculture and into a Department of their own. Every other nation which attached a proper value to its fisheries had, in the last thirty years, made a department of them, and with remarkable success.

The paper read was—

THE STATE AND THE FISHERMAN.

By MORETON FREWEN.

The great crisis through which Europe is now passing must inevitably turn men's minds to the problems of the ocean. The world we inhabit is made up of seven portions water and three portions land. It is no extenuation of the crime of Germany if we admit that no first-class nation can in these days enjoy any real place in the sun unless it has also easy access to the sea, and this not merely to a port here and a port there, but through the possession of a wide littoral. When the history of these days comes to be written, we may discover that the decline and fall of modern Germany and Austria were inevitable, and were not owing to the jealousy of rival nations, but to the evident geographical fetters by which those communities were cribbed, cabined, and confined. Germany is by nature a poor country, but inhabited by a vigorous, highly educated, progressive people, who have built up a vast and artificial industrial mechanism on a foundation of successful foreign, water-borne trades, the expansion of which trades is only possible by permission of their neighbours—a permission which will always be contingent on good behaviour. Thus the German peoples have enriched themselves, relying on a toleration which will in future be withdrawn. Probably the days of Germany's foreign commerce and factory system, did she know it, are already numbered; a large proportion of her people may again, as before 1870, find relief through emigration, and those who remain in their Fatherland will revert to more restful and agrarian occupations. Not so the British Empire, France, and the United States, nor indeed Russia, should the future of Russia include the lines of the Bosphorus. Such nations as these, their heritage enriched by easy access to the sea through numerous ports, will be found, in the centuries at hand, the fittest to survive. And the relative economic advantage of this access to the sea must all the time grow greater and not less. Modern mechanical developments tend to aggrandise the ship rather than the railway train. It is safe to say that the cost per ton per mile for railway freights will always be ten times greater than for ocean freights. Even the prodigious developments now at hand in aeronautics are likely to be chiefly valuable as ancillary to the shipping interests of communities. It is not the purpose of this paper, however, to point out why German prosperity for the past hundred years has resulted less from her successful predatory onslaughts on unready neighbours than from the spread of those economic theories amongst the non-German peoples which had for their objective a cosmopolitanism with which it is difficult not to sympathise, and which theories have been to us and to others a menace, chiefly because they do thus attract our philosophic sympathies.

These economic portents arising from the Great War will deserve the consideration of a new generation of students, and will no doubt

work their way through the Western legislatures after considerable delays and with differing results. Paul Voigt, a careful German economist, wrote some years since this note of warning, which perfectly exposes the Achilles heel of modern Germany. Voigt says:—

"The loss of our export trade would bring starvation to the masses of German workers and compel them to emigrate and to beg before the doors of foreign nations for work and food. The collapse of our export trade would be the most terrible catastrophe in German history, and would rank with the Thirty Years' War as a calamity. It would wipe out the German nation from the great nations of the world, and might end its political existence."

But it is to quite another ocean, to the ocean as a source of food supply, that this paper invites your consideration to-day. Our people, the world over, are the greatest of the meat-eating races. We have awakened to the recognition that the world is confronted with a very alarming shortage in its meat supply, and unless for a quarter of a century to come we can develop a more vegetarian habit, the meat problem appears quite insoluble. It is here that the fisherman, with the generous assistance of the State, may come to our aid.

I recall many years ago, I suppose at least forty years, reading a very interesting letter to the *Times*, written by the late Sir John Lawes. In this letter Sir John Lawes pointed out that the meat yield per acre of the English Channel off the Nore was equal to the meat yield of about a hundred acres of the best Northamptonshire grass land. Sir John Lawes wrote to support a theory that the more sewage our great cities dispersed to the sea, the larger the yield of fish. But great though his authority in this field of cosmic chemistry, I think it has since transpired that the meat yield of the ocean is not related, and happily not related, to cities and to the sewage problem; but it is related rather to the food supplies for fishes which Nature has herself sowed in one ocean more lavishly than in another. As I shall point out later, nowhere is the ocean common so fabulously fertile in fish life as in the North Pacific, from Behring Straits to Vancouver, and yet this is a region where its waters are less polluted by the sewage of cities than any other in the world—unless the Arctic and Antarctic. However, theories apart, the fact remains that the great ocean off the shores of our British Islands is very rich in food. In the Report of the British Sea Fisheries Commission of 1867 (Vol. I. p. 16), the weight of fish sold daily in the London market was given at 300 tons, which at that time was nearly the weight of the beef sold in London. Three hundred tons of fish per day! Truly such a figure looks imposing. But let me contrast it with an estimate prepared for the United States Senate, in 1887, by that very competent authority, Professor Elliot, of the yearly fish consumption of the seal herd of the Pribyloff Islands—six million tons a year, or some fifteen thousand tons per day! Congress at that time was being invited by our Government, and by the Canadian Government, to suppress pelagic sealing—the killing of seals on the high seas. The Pribyloff seal herd has since, and perhaps in consequence of Professor Elliot's evidence, been largely reduced; but whether the fabulous fish supplies of the North Pacific show any increase since 1887 I have no evidence to show.

Our time will not permit me to go more fully into this problem, namely, whether an acre of water or an acre of land has the greater productivity. It is a question of great importance to our sociology, and, in the days at hand when the prices of beef and mutton will probably be much higher, will lead to frequent discussion. It is enough now to point out that everywhere the modern State must treat its fisherman as it treats its soldier, and by all the means at its disposal the State must protect our great ocean pastures, restoring the balance of Nature, where necessary, by destroying predatory and worthless birds and fishes. Here is a British industry in which the capital employed is only some £12,000,000 sterling, and yet the gross annual return is over £10,000,000—a return to capital far greater than is the case in any other industry; and yet our entire State expenditure on our fisheries, both salt and fresh, is only £40,000 a year. Compare this expenditure with £207,000 a year in the case of Canada, and at least £700,000 a year (Federal and local) in the United States. The fishing cobbles and smacks of our coast counties are the real cradles of our merchant marine and of our warships too. Great Britain's fleet of steam trawlers to-day exceeds in number all the trawlers of Europe combined, and yet our national expenditure on our fisheries is hardly more than that of Norway and Sweden, and only one-fifth of that of the Dominion of Canada.

Let me now ask attention to the modern history of the famous American shad (*Clupea sapidissima*). This is one, and the very best, of our anadromous fish—fish such as the salmon, which feed and fatten only in the ocean, but

which are impelled by nature to ascend our rivers in order to spawn. The American shad is of all their table fishes probably the best. When England first colonised the Atlantic seaboard, the shad, during its spring migration, was the cheapest and most abundant of all their river fishes. But towards the middle of the last century this important food fish had been almost extirpated. Even as the canvas-back duck to-day, the shad was the dish of the millionaire. Mr. Seth Green, who, next to Professor Spencer Baird, may be regarded as the father of the American school of ichthyology, was able, after innumerable experiments carried on at the cost of the Federal Fishery Department, to hatch the eggs of this fish in syphon jars—jars that resemble a soda-water fountain. From this development, hardly noticed at the time, all else has followed, until to-day the shad is again one of the most important of the American food fishes. Re-established in the Atlantic by these cultural methods, next, in 1871, it was transported by the California Fish Commission from the Hudson River to the Sacramento River on the Pacific. The report of the Washington Department for 1898 has this to say of a modest planting operation:—

"Remarkable success has attended the stocking of the waters of the Pacific coast northward from Monterey. In 1871 shad fry from the Hudson River were liberated in the Sacramento River by the California Fish Commission, and in 1873 the U.S. Fish Commission made a second deposit of 35,000. Subsequent plants in the Sacramento, aggregating 609,000, were made by the U.S. Commission. From these small colonies, amounting to less than one per cent. of the number now annually planted in the Atlantic coast rivers, the shad have multiplied and distributed themselves along nearly three thousand miles of coast from Southern California to South-Eastern Alaska. The shad rapidly made their way up the coast from San Francisco Bay. They reached Rogue River, Oregon, in 1882. In the Columbia a few were taken as early as 1876. About 1881 they were on the coast of Washington, reaching Puget Sound in 1882, they appeared in the Fraser River, British Columbia, in 1891, and in the Stikine River, near Wrangell Island, Alaska, lat. 56° 30′, the same year."

I may gratefully record that the officials of the Washington Department, with their accustomed public spirit, sent me nearly two million shad eggs and Green's syphon jars, some years since, to Innishannon in Co. Cork, thinking it possible that by the very fastest passenger steamer some of the ova might arrive alive. But all died in transit. The period of incubation for the ova of this fish is only five days, and a successful experiment would involve either, as in the case of the California experiment, the movement of the fry or the hatching out of the eggs with fresh water on shipboard.

I have drawn your attention to the very short period of the incubation for the ova of the shad, which makes it impossible to import eggs from a river in America to be hatched in this country. In the case of the ova of all the salmonidæ this is not so. I have delivered eggs of the rainbow trout (*Salmo irideus*) in perfect order in New Zealand. And it is well to recall that, thanks to the public spirit of Messrs. Hinde and Grogan, the ova of the ordinary brown trout (*Salmo fario*), only eight years ago, travelled out to East Africa by the ship in which I was a passenger, and, after hatching, the fry were planted in that lovely mountain stream at Nyeri on the slopes of Mount Kenia. So that to-day trout, often 4 or 5 lbs. in weight, swarm throughout the Kenia watershed, an addition of untold value to the worth of life on that plateau than which there is nothing finer, whether in climate, sport, or scenery, under our flag. I should expect the beautiful but elusive rainbow trout, which has been a disappointment to us breeders in Great Britain, to prove a success in the mountain streams of Kenia and the Victoria Nyanza. The rainbow trout is probably the steelhead salmon (*Salmo gairdneri*) of the Pacific, that by some accident had got land-locked. Released in our streams, he starts off without delay to his ocean home, though, unlike his cousin *Salmo salar*, the rainbow has no homing instinct for the river which rocked his cradle. But from the streams of this African plateau it would be impossible for the rainbow trout ever to reach the ocean. After travelling a couple of hundred miles, the river water under an equatorial sun becomes much too heated for the further passage toward the ocean of any of the salmonidæ. In the *Nineteenth Century Review* for September, 1899, I gave a detailed account of the operations of the United States Fish Commission, and described the spread of trout hatcheries in the Rocky Mountain area as constituting a valuable cottage industry. Of the trout farm of Mr. Sherlock, two miles from Salt Lake City, I wrote: "Mr. Sherlock tells me his feed bill for a quarter of a million fish is but a sovereign a month, and he retails his produce for 2*s.* a pound. The yield of his quarter acre of artesian well water is not less than £600 a year."

In addition to the shad, another splendid Atlantic fish, the striped bass, was moved by the Federal Fish Commission to the Pacific. The report of the Commission (1896, p. 141) has this to say :—

"The market value to the fishermen of the Pacific coast of the shad and the striped bass, taken between 1888 and 1896, was about 192,000 dollars. The aggregate expense of introducing these fish to the Pacific was under 5,000 dollars."

Two generations of men have come and gone and few dwellers on the Pacific now recall that fifty years ago, and at a cost of only a thousand pounds, these two superb table fish were presented by the Atlantic to the Pacific, and that the dwellers to-day on three thousand miles of coast-line are, did they but know it, the beneficiaries forever of that prodigious legacy bequeathed to them in 1871 by the Federal Fish Department.

Read also the report of the Canadian Fishery Department for 1899 :—

"On July 8th there had been planted in the waters between Caribou and Pictou Island a hundred million young lobsters. Each year adds more lobster factories on our coasts and more traps on the fishing ground, and it is surprising to all that the lobster fishing is holding out. The fry from the Bay View Hatchery has been planted in Pictou Bay, and I agree with the packers and fishermen who believe that the good fishing around this locality is largely due to the hatchery."

The recent history of that superb fish, our *Salmo salar*, in the United States, is of all the most interesting. When the Pilgrim Fathers reached New England this fish swarmed into every river in New England. Fifty years ago in those rivers and the rivers of Maine and New York State, *Salmo salar*, owing to river pollution, sawdust and traps, had become practically extinct. Next the ova of this fish, purchased from the Canadian Government for £10 a thousand (a large hen fish would carry twenty thousand) were hatched, and the fry liberated in the Penobscot River. To-day the yield of that river is some ten thousand salmon a year, and *Salmo salar* from a score of New England rivers is now fairly cheap in all the markets of the Eastern seaboard. In these islands of ours, were the State to tackle resolutely the salmon problem, the price of this fish, which is now prohibitive, might well be reduced to 6*d.* per lb. But this problem of salmon culture is hardly less controversial than is Sir Robert Peel's Bank Act! It is technical in the highest degree, and with regret I must regard it as quite outside the scope of this paper. It is enough now to say that the anadromous fishes, such as the sturgeon, the salmon and the shad—all fine food fishes that pasture only in the ocean, and from those feeding-grounds bring a feast of fat things a hundred miles up our rivers to our very garden gates—fish these which make no demand on our rivers for their food—should constitute an important, welcome and cheap source of food supply in these islands. I take the following figures from a recent report of the California Fish Commission. Mr. Smiley writes of the operations of the great State salmon hatchery at Baird, that its annual yield, at an average weight of 7 lbs. per fish, is 4,391,882 lbs.; the selling price of salmon is 3½*d.* per lb.; the cost of hatching and distributing is £720 per year. Of another of their State hatcheries, at Battle Creek, he writes that nearly fifty million salmon eggs are being secured each season. On such a scale are the operations of the California State Commission. The Federal Fish Commission, operating from Washington, supplements the activities of the various States by hatching and distributing free of charge two hundred million lobsters and more than a thousand million fish of all sorts.

From what a small beginning—the mere hatching by Green of a tiny embryo in a syphon jar—the great shad fisheries of two oceans date their prosperity! And scientific successes perhaps equally important await the Frank Bucklands, the Seth Greens and the Spencer Bairds of to-morrow. For we stand to-day upon the threshold of the unknown. What alone we know is that the entire biology of the ocean involves an endless chain of life evolved from death. There is a shrimp so atomic that eighteen thousand have been counted under a microscope in the stomach of a single herring. Thousands of such herrings are required for the daily provision of a single whale. It used to be said that Holland, Mistress of the Seas, with a vast world-wide commerce, was built up on the herring; but the fact remains that in the ocean every intervening organism in the vast continuous chain of creation, culminating with the giant sperm whale, is based upon a shrimp scarcely visible to the unaided human eye. I have touched on the triumphs of science in creative operations—in the hatching of shad and lobsters and salmon; but perhaps equally important, if we are to get the full harvest of the ocean, is it that we should undertake the careful destruction of worthless and predatory fishes and birds. It is conjectured that the

gannets off our coasts consume more herrings than are captured by all the nets. The destruction of salmon smolts in our estuaries by sea-gulls very probably aggregates one half of all the salmon smolts which run down our rivers. That worthless bird the cormorant, it is known, consumes daily 50 per cent. of its own weight in fish. I confess to the desire to see the ranks of our cormorants, and herons also, greatly thinned. And yet any such process of elimination must needs be exercised with great care. For example, one of the worst enemies of the net fisherman is the dogfish, which often takes a heavy toll of the fish enmeshed in our stake-nets. But, on the other hand, the principal food of the dogfish is the starfish, and the starfish is voracious of the spat of the oyster. When Professor Elliot pointed out that the fish consumption of the Pribyloff seal herd in the North Pacific amounted to six million tons yearly, we must not assume that this mass is chiefly salmon and halibut, the two most valuable of the North Pacific fish. It is probable that the seals consume a proportion of coarse fish, which fish themselves prey upon the more valuable food fishes. There is everywhere, and especially in the case of the ocean, a mysterious imponderable balance in Nature which man must be careful not to upset—a balance, did we know it, not less important than is the balance of power in Europe.

I now come to a consideration which is of all the most essential before we can establish our claim for liberal expenditures by the State. If we regard the ocean as a source of supply for the mere raw material of the wealth of nations, what is the cash return to the labour employed on this material? I believe it can be proved that, of all our primary industries, the ocean fisheries require the very smallest capital outlay and yet pay the very richest return of all to the labour employed. If this is the case, then any deputation which waits upon any Chancellor of the Exchequer on behalf of our fisher folk occupies ground of great advantage. I have already noticed that the capital employed in these islands—our ships, our boats, our nets, etc.—aggregates twelve millions sterling, and that the gross annual income derived is not less than 90 per cent. There are 80,000 workers in this field; probably one-third of these are boys whose wages in field or factory work would be small. Thus the yield per worker is £125 per annum, and by referring to our new Wealth Census of Production we discover that the value of the product of the skilled worker in our factories (if we deduct the cost of the raw material supplied) averages a full third less than the value of the product of the fisherman; and in the case of agriculture the yield is a full half less. Some years since I investigated the wealth yield of the Canadian fisheries. In 1885 there were 60,000 hands employed in 1,177 vessels and 28,472 boats. The total capital expenditure was £1,200,000 only. The entire population, both workers and dependents connected with the Canadian fisheries, numbered 147,543. The gross value of the catch in a season of four months only was over three and a half millions. Whereas when I was in New South Wales in 1896 there were in that Colony 160,000 people connected with agriculture, and the value of their product was for the full twelve months only three and a quarter millions. I should point out that these figures would require some adjustment to-day, as in the past fifteen years agricultural products have advanced in price more considerably than the price of fish. In the case of the four States of Pennsylvania, New York, Maryland, and New Jersey, the capital invested in fisheries is £3,000,000 and the gross annual yield is also £3,000,000; the wealth product for the year per caput (and in this I include all the dependents) is no less than £121. In Lake Ontario again 206 hands are employed during a season of five months in connection with the white-fish and lake-trout fisheries. The value of their take in the five months is nearly £217 per caput.

I must not occupy our time by enlarging on these returns. It is enough to say that the return to the labour of a pair of hands at sea is far greater than the return on land. Only in the case of highly-skilled labour employed on highly-priced raw material, where, indeed, the value of the raw material is one-half or even two-thirds the value of the finished product, can we show such earnings as those which comparatively unskilled labour derives from that great ocean common which is free to us all.

I shall conclude by drawing your attention to the really amazing marine biology of the North Pacific Ocean. In preparing this paper at this time I have desired chiefly to invite public attention to the stored wealth of that ocean, hoping that, on some of the numerous and beautiful islands lapped by the Pacific, fishing colonies may be established for partially disabled soldiers and sailors, and, indeed, for those soldiers and sailors who suffer from no such disability, but who aspire to the wider and freer life which awaits them in the outer Empire. In my mind's

eye I can see a score of beautiful and at present desert ports and harbours along the coast-line from the State of Washington to Alaska, where Nature, as in British Columbia, has done her work with a partiality and a prodigality quite unknown elsewhere. Such sea fisheries; such river fisheries; with a season not as in the Atlantic of five months, but of at least ten; the fishing operations conducted not as in the North Sea or in the west Atlantic, under conditions of great hardship and even danger, but in the security of beautiful land-locked fjords and on summer seas. These are conditions which must insure, given this increasing pressure on our meat supplies, the very rapid settlement of that beautiful coast. A colony of ex-soldiers and sailors, a proportion of the number carpenters, blacksmiths, and masons—the larger their families the better—who will charter a ship, can now conclude a continuous voyage *via* Panama at some well-sheltered harbour in the Queen Charlotte Islands, within three weeks from Liverpool. The sawmill they take with them will clear their townsite of the big timber trees and convert these speedily into houses. On the coast of British Columbia the contract price to-day of a spacious four-roomed cottage with kitchen and bathroom is only £100.

Of these Pacific fishing-grounds Professor Edward Prince, of the Dominion Commission of Fisheries, writes:—

"These fisheries are amongst the most prolific and valuable in the world, and they are capable of immense expansion. Their leading feature is that they can be carried on in waters perfectly land-sheltered. Hecate Straits, Dixon's Entrance, Queen Charlotte Sound, and the Straits of Georgia, with innumerable deep inlets, bays, and arms, are so shielded from the ocean as to furnish unique conditions for the pursuit of fishing. The investigations carried on by a committee of the British Columbia Fishery Commission of 1906, proved that extensive feeding-grounds for fish occur on every part of the coast. The bottom is in numberless places literally alive with invertebrate animals, especially shell fish, anelids, shrimps, and sand stars, which constitute a very large part of the food of the most esteemed kinds of marketable fish. The greatest spawning and feeding-grounds in the world for herring, cod, plaice, halibut and numerous other food fishes occur within this vast and sheltered area, which covers nearly thirty thousand square miles. The Fraser River, Columbia, Thompson, Skeena, Naas, Stikine, Liard, Yukon and other vast rivers, all have their sources in British Columbia, and most of them rank as the greatest salmon rivers in the world."

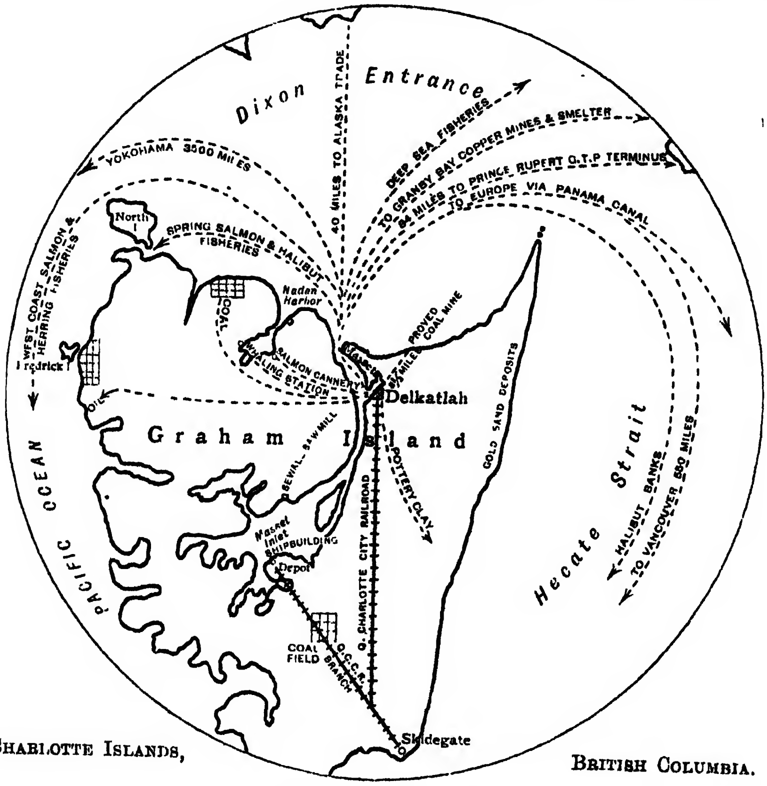
From September to April the fish are taken on long lines in the deep water; from April to July the fish, especially the halibut and salmon, come in vast shoals into the fjords, harbours, and estuaries. Colonel Newberry states that while on one of the steamers of the New England Fisheries Company he tallied a capture of 165,000 lbs. of halibut in five hours. Sir Richard M'Bride, the Premier of British Columbia, was probably on safe ground in saying that "experiments have established the fact that an hour's trawling on the Atlantic coast of Canada will bring up more fish than can be captured in six hours in the North Sea fishing-grounds, and as it is conceded by the best authorities on the subject that British Columbia's fisheries are immensely more productive than those of the Atlantic, it follows that our fisheries would support a million people without taxing them to an appreciable extent."

Hitherto the fish of this region has had to be carried south by any passing steamer six hundred miles to Vancouver or to Seattle, and from one or other of these ports conveyed by rail to the eastern markets; but last summer the Grand Trunk Railway system was completed to the Pacific Ocean, at the harbour of Prince Rupert, and is already delivering fish, chiefly halibut and salmon, in car-load lots of 20 tons at Winnipeg, Chicago, and Montreal, and at a freight cost of only 1½*d.* per lb. to Montreal, some three thousand miles east.

The great cold storage fish market in Prince Rupert pays over the counter 2*d.* a pound for halibut and 3*d.* for salmon. Beyond question a very few years will discover Prince Rupert to be the greatest fishing port in the world. When we consider the land-locked conditions under which the fisherfolk in these regions ply their trade; their safety from storms; the length of their season; the incredible wealth of their ocean; the fact that they have a continent with over a hundred millions of people to supply—people whose purchasing power and food-consumption is built up on a rate of wages nearly three times higher than Europe's—it is difficult to resist the conclusion that the cash return to each pair of hands employed in these Pacific fisheries must be three or even four times greater than in the case of our home fisheries. The settlement I have in mind might be on the north shore of Graham Island, eighty miles west of the new town of Prince Rupert. The distance from Prince Rupert to Yokohama is only 3,500 miles, and this new route to Japan will save two or even three days over any existing route from Europe. A service of fast passenger boats from Prince Rupert to Japan

is projected for 1917, and these boats, passing along the north shore of Graham Island, will give that great island and its industries most convenient access both to the mainland and to the Orient. The soil of Graham Island is said to be fertile, and already vegetable and dairy products from its settlers are coming by a weekly steamer to a good and growing market in the town of Rupert, which, founded in 1908, six years ahead of any railway connection, has already a population of over seven thousand people.

famous in the history of the Pacific coast, will work for the future of the Queen Charlotte Islanders even while they sleep. And from Northern British Columbia as a centre, great industrial developments now radiate. If we include the coming expenditure of the United States on the Alaskan railroads, for the immediate construction of which Congress last year voted seven millions sterling, it is safe to say that during the next five years twenty millions sterling will be spent in railway construction in the immediate vicinity of Prince Rupert. The



CHARLOTTE ISLANDS, BRITISH COLUMBIA.

If a colony of five hundred people, to include wives and children, were planted in some carefully selected harbour of the Charlotte Islands, and a sufficient area on the harbour were surveyed and secured to accommodate a future town of ten thousand inhabitants, the rapid advance in the value of the townsite lots will in the next few years enable such a settlement to finance itself on a most generous scale. The operation of the Panama Canal, revolutionising as it must trade relations between the Orient and the Occident; the opening through to a really magnificent harbour, Prince Rupert, of the Grand Trunk system—these two events, which made 1914

coming summer will see completed at Prince Rupert by the Dominion Government of Canada the greatest dry-dock on the entire Pacific coast, a dock capable of receiving a ship of 25,000 tons. And while the rate of wages in British Columbia is about the highest on the American Continent, the cost of living, if I exclude the southern States of the Republic, is probably the lowest. Cheap food supplies from the great prairie provinces of Saskatchewan and Assiniboia are near at hand, and, looking west, now that direct trade connections are about to be established with China and Japan on the coast opposite, there should be a downward trend in the price of clothing and other

commodities manufactured by cheap Asiatic labour.

But to conclude. What is the real outstanding lesson of this bloody war? Surely it is the value of the fighting man, and the value of the mother of the fighting man. How, then, can we in future keep our citizens within our own community—how fill our own waste places with our own people? The late Mr. Blaine, of Maine, once priced to me the value of an able-bodied immigrant of either sex at £300. Does anyone to-day regard that estimate as excessive? Depend upon it a generation of our statesmen of the future, who are to-day in our schools, will discover that the national policy of the British Empire is founded on that recognition and no other—the value of the *Civis Britannicus*. For the past fifty years, owing to "the canker of a long peace and quiet times," we have ignored entirely the value of the man; we have with a light heart flung our men out, sink or swim, into any foreign citizenship.

We shall now discover that any expenditure is profitable which will keep our own people both prosperous and in touch with us, and no finance has an economic foundation so well and so truly laid as that which assists our people to do business in the great waters where it is their privilege from day to day to bear grateful witness to "the works of the Lord and His wonders in the deep."

DISCUSSION.

THE CHAIRMAN (the Right Hon. Walter H. Long, LL.D., F.R.S., M.P.), in opening the discussion, said Great Britain had undoubtedly been troubled by the problem of excessive population. It had puzzled all thinkers, especially social reformers, and it was well known that years ago Cobbett foresaw in the growth of our towns the destruction of what he called English life and all that was best in rural life conditions. This country very suddenly went through a great change. Having been a rural country, and having faced the last great war, which was in any degree to be compared with the present conflict, with a population infinitely smaller than the present population, all at once we developed our great commercial position. Some of our largest and most prosperous towns grew like mushrooms in a night, and the whole nature and face and condition of the country were altered. That change had been steadily progressing. When he first entered Parliament, some thirty-six years ago, the House of Commons was beginning to change, but it still retained at that time a great deal of its old complexion. A great many of the old country elements were left. What was called the "country gentlemen party" was at that time a powerful party with a great historical past and with great influence; but the influence of the towns had made itself felt upon each successive Reform Bill, and as time went on it had been found necessary to give increased representation to the big towns. As he had said, the population of this country had increased enormously, and between twenty-five and thirty years ago, when it had been his duty to look into the matter with the hope of discovering some solution for the difficulty, the idea of emigration occurred to a certain number of people. That idea, however, had been contemplated with horror by a great many persons, especially by those who claimed the right to speak for the working-classes. They said, "You say there is no room for the people here. You advise them to emigrate. In other words, you tell them to leave their own homes and their own kith and kin and go to distant lands." He hoped that one of the changes that had taken place during the last few years preceding the war would be emphasised by the war, namely, that the word "emigration" would be forgotten as regarded the British Empire, and the word "migration" be substituted in its place. In other words, that it would be realised, as it had never been before, that the British Empire was one, and that to go from England to Canada, or from Australia to England, or from South Africa to Australia, was not emigration—going from home to a strange land—but was merely migration, going from one part of one's country to another. If he were right, then surely the paper was of enormous value, because if our people could be told that they could not only move from one part of the Empire to another with the certainty of finding there people of their own kith and kin, but that in addition there were open to them vast fields of wealth which they could occupy and develop for themselves and for their country, surely the solution of some pressing social questions would be nearer to accomplishment than ever before. Large numbers of magnificent fellows had been fighting as even British soldiers had hardly ever fought before in the whole of our long and glorious history. Think what the strain must have been on their minds as well as their bodies of continued trench warfare. Was it not probable that a great many of them, after spending their time in such tremendous excitement, would never consent to resettle in the narrower surroundings of the old and developed land at home? They would ask for some place where they could open their arms and stretch their legs and feel there was room to turn round, and this country ought to be ready to point them the road to lead them to what they wanted and which would give them an assured future; and the paper showed one of the ways.

MR. W. H. PIBEL said he was afraid very little had been heard that night about the state of the fishermen. What the author had said about the

wealth of the Canadian fishery was right and true, but that did not affect the fishermen of this country, for whom there was plenty of work here. In passing he might draw attention to the fact that there was one class of men who had done even more than the soldiers and sailors (of whom he desired to give the greatest praise) for the good of the country, and that was those men who went trawling for mines; and the man who had done the greatest work among those men was perhaps the man who was least considered, namely, the stoker in the hold. Those men were fishermen, and it was to be hoped they would be fishermen again; but the difficulty which had to be considered was that at the present moment, the quantity of fish being caught being less than half the normal amount, the means and methods of distribution were getting gradually less, and if things continued as they were, when the fishermen came back again they would find great difficulty in getting a market for their fish. What had to be considered was not the emigration of fishermen, but seeing that the work was available for them when the war was over.

Professor E. W. MacBride, F.R.S., said there were one or two points in the paper which had rather surprised him. One was the great reliance which was placed on the hatching of fry as a means of increasing the yield of fish. He was quite prepared to believe, in the case of fish which laid their eggs in fresh waters, that this had been of service in the past and would be of service in the future, but he had the authority of one of the greatest fishing experts in the world, the Superintendent of the Fisheries of Norway, for doubting the value of any such process when applied to salt-water fish, and especially in the case of lobsters. With regard to the question of the future of Canadian fisheries, he quite agreed with the author as to the enormous fecundity of the Pacific coast of Canada, but one great difficulty always occurred in all schemes for increasing the fishing population on the Pacific coast, and that was the great distances to the markets. It had to be remembered that the fish, even after being landed, had to be carried over 600 miles of mountains, and then had to be conveyed several hundreds of miles on the railway before it reached a market, and that market was not like the London market, but one of comparatively small size. He thoroughly agreed with the previous speaker that this country could not be too grateful to the fishermen for what they were doing in the present war, and for that remark he had the authority of Lord Lucas.

Mr. G. L. Alward said the idea of drafting out a surplus population to deal with the Canadian fishery was a most laudable one, but the difficulty in Canada was exactly the same as in this country, namely, of getting the fish distributed, and also, in the case of Canada, of educating the people to eat the fish. Before anything serious could be done in the matter it would have to be found out how long it would take to develop the same desire for fish among Canadians as at present existed among persons in this country. With regard to a remark of the last speaker, he had seen fish which had been sent overland in Canada, and it had not been in a very enticing condition on arrival. For those reasons he considered it was not quite possible yet to send soldiers and sailors to that distant part of the world with the certainty that they would have before them a great future. He also endorsed the remarks of Mr. Pibel. The trawling industry had provided this country with such a defence as no other country in the world possessed.

Mr. R. R. Prynne said he had noted several points in the paper which, it seemed to him, would draw to a certain logical conclusion, but which, in the end, did not do so. The author had pointed out that the amount spent by our Government was about one-third the amount spent by the Canadian Government on fisheries; that many years ago certain rivers could produce great quantities of edible fish, but became polluted; and that in many cases experiments had been tried to repeople them, with perfect success; he had further pointed out that fishermen were a very valuable set of men; also that in many cases the prolificacy of fish round our sea-shores was hindered considerably by sea birds and other nuisances. Those points all seemed to him (the speaker) to draw to the conclusion that the Government of this country might do quite a great deal for fishermen, to the fact that State legislation was needed in order to fasten our fishermen more firmly to their native coasts, and that legislation should do something towards increasing fishermen's interests round the shores of Great Britain. But the author, after making all those points, had come to what seemed to him (the speaker) to be a most lame and impotent conclusion, namely, that the fishermen should be sent away to the other side of the world. He would venture to point out that if they did go to the other side of the world they would not be available to catch fish for the people of Great Britain; they would not defend our shores; they would not come back to their homes; in fact they would be lost altogether to this country, and would go somewhere where they would have to start catching fish all over again.

Mr. W. Simnett said he confessed he had been rather disappointed that no reference had been made to the work of the Fisheries' Organisation Society in particular. He thought one important question to be dealt with was in regard to the inshore fisheries of this country as affected by the conditions which would arise after the war. It had already been pointed out that the channels of distribution were somewhat drying up. That was an important point, because the central work of the Fisheries' Organisation Society was concerned with the organisation of fishermen in

co-operative societies, and their mainstay and greatest hope was in getting better markets for their fish. In that connection he desired to raise the point of the possibility of State action in increasing the channels of distribution and the markets for fish. The author had drawn an extremely attractive picture of the fishermen's Utopia abroad, but he (the speaker) thought that those who would be most drawn by the description would be the present fishermen rather than the returned soldiers and sailors. It was not to be desired that the present fishermen of this country should be attracted abroad.

DR. F. G. OGILVIE, C.B., thought that owing to an unfortunate omission at the beginning of his paper the author had created an impression which he had not intended. In the first place, the Department which was in charge of the fisheries of this country was the Department of Agriculture and Fisheries, and, while that was a single Department so far as representation in the Cabinet was concerned, it was a Department with two distinct staffs. One of these was specially charged with duties in relation to fisheries, and included men specially qualified for expert service in connection with fisheries. This fact rather bore on the points which had been referred to by previous speakers. It was a matter of common knowledge that the Government in recent years had been devoting a very great deal of attention to what it was best to do in order to promote the fisheries. They had not been prepared to cast gold upon the waters without consideration, and it might be they were taking longer time to think about it than people liked; but there was no doubt that the schemes now in hand involved sums considerably in advance of those quoted by the author. He would like to ask one question. He thought it was recognised that the author was asking the audience to look, not at the whole relation between the Government and the fishermen, but only at one particular aspect of the relation of the Government to fisheries. The paper in effect was a long suggestion that there was a possible outcome for valuable services in connection with fisheries elsewhere—an outlet for men who were not fishermen. But he must say that, having been a long time closely connected with fishermen, he had come to look upon fishing as being an occupation that had hitherto, at any rate, depended so largely upon traditional expertness, traditional familiarity with the sea and with fishing, and an early familiarity with the methods to be employed, that it was not the sort of occupation it would be wise to ask a grown man to take up, unless he had had some early experience which fitted him for it. Had the fisheries on the west coast of Canada features which made this unnecessary?

THE AUTHOR, in reply, said he was quite sensible of the advance in connection with ichthyology which the Department had made in the last few years. A very valuable amount of information had been collected, and our ichthyologists were second to none; and he should be very sorry if it went out that he was indifferent to the fostering care of the Government in the last ten years. Still, he thought it desirable there should be a separate Fisheries Department, with larger appropriations. In lobster hatching and lobster culture, the view of the professional mind in this country, as evidenced by Professor Macbride's remarks, was that the results from cultural operations were inadequate. All he could say was that in localities in Canada, or in the United States, where those operations were most extensively carried out, the fisheries seemed to be extremely prosperous, and the local community gladly accepted the taxes imposed for the purpose. The fact was, with regard to all Government departments, that a man of advanced age in any position of authority always fell in very slowly with any new experiments which some other country might be carrying out with great success, because it seemed to throw discredit on his past life's work that such experiments had not been attempted here earlier. With regard to Professor Macbride's criticism about the carriage of fish, the Grand Trunk system had made arrangements whereby every train running from Prince Rupert East had now one to six refrigerator cars carrying fresh fish. At the present moment London was receiving Prince Rupert halibut in good condition. It seemed to him that disabled soldiers and sailors would be quite equal to the work. It was the most unskilled labour in the world. It required no knowledge. Coming out of the harbour with Mr. Stewart, the contractor for the Grand Trunk Pacific Railroad, recently, that gentleman told him that one of his railwaymen had put a deep-sea line, with a number of hooks, in the sea overnight, and in the morning he pulled out 3,000 lbs. of halibut. Such fishing required no skill whatever. He had regarded the question of the national service which was being performed by our trawlers as outside the scope of the paper. He only treated a very vast problem from the point of view that we were threatened with a meat famine, and that the State should do everything to foster the fisheries and give a well-distributed fresh fish system, including fish from the Pacific Ocean.

On the motion of the CHAIRMAN, a vote of thanks was accorded to the author for his interesting and valuable paper.

TEA FROM NEW SOURCES.

The cultivation of tea, says the latest quarterly issue of the Bulletin of the Imperial Institute, has been attempted in a number of British possessions outside India and Ceylon, and notably in parts of Africa. The industry in Natal and Nyasaland has already been referred to in this Bulletin. Experiments in tea-growing have been made by the Department of Agriculture in the Southern

Provinces, Nigeria, and two samples of the product have been examined at the Imperial Institute: they proved to be of good quality. Samples of tea have also been received from Uganda, East Africa Protectorate, and Fiji, and these are dealt with as follows:—

UGANDA.

Tea-growing in Uganda is at present only in the experimental stage, two plots being grown at the Government plantation at Kampala. In the lower plot, situated near a drained swamp, the growth has been good, but in the other, at a higher level, the plants are stunted and make little or no progress. A sample of tea grown and prepared at Kampala was received at the Imperial Institute in November, 1913. It consisted of rolled black tea, dry and in good condition, but of somewhat uneven colour, a small quantity of light-coloured leaf being present. The tea was chemically examined, and the tests showed that when compared with the results obtained at the Imperial Institute for Indian and China teas the present sample of Uganda tea is rich in caffeine, tannin, and extractive matter, and that in this respect it resembles Indian rather than China tea.

The sample was submitted to a firm of brokers, who reported that it represented a blackish, rather bold and mixed, unassorted tea, with some white tip. The liquor was of fair strength, with some quality, but was very light in colour; and the infused tea, whilst generally of good colour, was uneven, with some greenish leaves. The brokers stated that the value of the tea was uncertain, but might be nominally about 8½*d*. to 9*d*. per lb. in London (January, 1914).

The brokers mentioned that this tea was very similar in style and appearance to a variety which used to be received from Java some years ago, called "Flowery Pekoe," but they added that the present sample had evidently not been graded. Compared with that of Indian, Ceylon, and Java teas, the liquor was in their opinion too thin to attract the competition of most buyers in London. They considered that the tea might with advantage be given a longer fermentation and also a heavier rolling, which would tend to increase the colour and strength of the liquor.

The firm added that the sample showed very fair manufacture, and if the suggestions made above were acted upon, they were of opinion that quite a satisfactory price would be realised in London, provided the tea came forward in marketable quantities of, say, not less than twenty chests at a time, each weighing 90 to 100 lbs. net, or twice the number of half-chests averaging about 50 lbs. net.

Two further samples of tea which had been fermented for a longer period than the previous sample were received from Kampala in January, 1914. They were as follows: No. 1, "Golden Tip"—dried, rolled tea, clean and in good condition, and varying from pale brown to black in colour, a large proportion of the paler leaf being present. No. 2, "Broken Leaf"—dried, rolled, black tea, mostly composed of broken leaf, and containing a small proportion of powder.

The teas, as received, were examined, and the result showed that when compared with the previous sample from Uganda, No. 1 contained a high percentage of caffeine. In other respects the tea is of normal composition, though the percentage of tannin is rather higher than usual. The analysis of sample No. 2 shows it to be of normal composition, and to resemble closely the previous sample of Uganda tea examined at the Imperial Institute, except as regards the percentage of tannin. The amount of this constituent appears to have been considerably increased by the longer fermentation to which the leaf had been subjected as compared with the previous sample.

The samples were submitted to a firm of brokers, who valued No. 1 at about 1*s*. 4*d*. and No. 2 at about 8*d*. per lb. in London (August, 1914). They added that the "Golden Tip" leaf, No. 1, was a somewhat fancy article which they considered could only be produced in small quantities. The firm stated that the longer fermentation to which these teas had been subjected, as compared with the earlier sample from Uganda, had resulted in some improvement in the colour of the liquor, but there is still a lack of strength in comparison with Indian and Ceylon teas. They suggested that this defect might be remedied by harder rolling.

EAST AFRICA PROTECTORATE.

Tea was first grown in the East Africa Protectorate on an estate at Limoru in 1904, from seed imported from India. The plants grew well, and localities similar to Limoru, where the rainfall is 60 inches or over in a normal year, and the air cool, seem well adapted for tea-planting. A sample of tea grown on this estate and prepared by hand was examined at the Imperial Institute in 1909. It was black tea of good aroma. The analysis showed that this tea from the East Africa Protectorate resembles Indian tea in the amount of extractive matter and tannin present, but that it contains an unusually high percentage of caffeine. The tea was submitted to a firm of brokers, who reported that it had, on the whole, been carefully prepared, that the twist of the leaf was good, but that the leaves were irregular in size, being unsorted. The liquor obtained on infusion was found to be of very fair quality, and the tea generally resembled that from several Ceylon gardens. The tea was valued at from 6½*d*. to 7*d*. per lb. (March, 1909). The investigation shows that tea of good saleable character can be grown in the Limoru district of the East Africa Protectorate with prospects of success.

FIJI.

A sample of tea, described as Orange Pekoe, from the Wainunu Estate, Fiji, was received for examination in July, 1909. It was a black tea, containing some tip, and was of fairly satisfactory appearance. The leaf was of a useful size, but somewhat broken. A chemical examination showed that the tea from

Fiji resembles the Indian teas in the percentage of tannin present, but that it contains a smaller amount of caffeine, agreeing in the latter respect with the China teas. The percentage of "extract" is between those given by the Indian and China teas. The firing of this tea appeared to have been carried out at rather too high a temperature, with the result that the sample smelt somewhat scorched. The infusion had but little strength, was light in colour, and tasted slightly burnt or "over-fired." The infused leaf was too dark and mixed.

The tea was submitted to commercial experts, who valued it at 7½d. per lb. (December, 1909). They stated, however, that this valuation was based almost entirely on the appearance of the tea. For the reasons already mentioned, the "liquor" was regarded as unsatisfactory, and in this respect the tea could only be classed with inferior descriptions. A better product would, no doubt, be obtained with more careful preparation.

NIGERIAN AND SOMALILAND LEATHER.

Nigerian leather has been exported to Europe and Asia from very early times, and it has always enjoyed an enviable reputation; but, in spite of this, practically nothing has hitherto been known about the methods in which the skins are prepared, tanned and dyed. Very considerable interest therefore attaches to an article on "Nigerian and Somaliland Leather," by Mr. Alfred Seymour-Jones, Chairman of the International Commission to investigate the preservation, cure, and disinfection of hides and skins, which appears in the *Leather Trades' Review*.

After describing the sources from which the skins are obtained—mainly sheep and goats—Mr. Seymour-Jones proceeds to discuss the preparation of Nigerian leather.

The methods of treatment followed by natives of West Africa, he says, agree in general principles but vary in details, according to the district. The operations divide themselves under the usual heads—(*a*) depilation, (*b*) bating, (*c*) tanning, (*d*) dyeing. The tools employed are crude, and the vessels are large earthenware pots. The tanning industry is widely distributed, and may be said to be almost a household occupation, but only in the sense of implying the extent to which the people follow that occupation and the relative smallness of each individual output.

On the skins being received from the local butcher they are in some instances washed, after which they are treated to an alkaline bath which compares with the modern method of liming. In some districts this bath is simply a mixture of wood ashes and water. According to Dr. Alexander, the Kanuri and Hausas, who are important producers of Niger leather, employ a strong alkaline preparation known as "toka," which consists of the ash obtained by burning the wood of the "Merki" (probably *Anogeissus leiocarpa*) or the "Anum" tree, or by burning the vegetable and other refuse from tanning and dyeing pits with wood from Merki, Anum, or Karumga (*Acacia Seyal*) trees.

A sample of "toka" has been analysed by the Imperial Institute with the following results :—

	Per cent.
Lime, CaO	18·45
Magnesia, MgO	2·93
Ferric oxide and alumina, Fe_2C_3 and Al_2O_3	7·79
Silica, SiO_2	69·96
Sulphate anhydride, SO_3	0·22
Phosphoric anhydride, P_2O_5	0·86
Carbon dioxide, CO_2	2·09
Water, H_2O	2·12

No organic matter was present, and the silica occurred almost entirely as sand. "Toka" is, therefore, very largely quicklime mixed with sand and other impurities, and its use as a depilatory corresponds with the similar use of lime in European tanyards.

The liming or depilatory process is carried through in the space of twenty-four hours, and the hair is scraped off with a blunt knife.

In the Ingra, Bobi and Kontagora districts of Northern Nigeria the depilation process assumes an interesting phase. Usually the skin is pegged and dried, yet it may be treated in the fresh condition. It is then placed in a calabash containing water and the powdered pods of an acacia, and left there for three days, after which it is removed, pegged out on a board and scraped with a bent knife until all the hair is taken off. The skin is then permitted to dry, and when finished is of a pearly white colour.

In consequence of the climatic conditions of West Africa, it is evident that some action other than alkaline plays the principal part in depilation. If similar skins were immersed in European lime liquors, they would take many days to depilate. It appears to be a clear case in favour of the bacterial theory as the chief agent in depilation. As the immersion accomplishes the act of depilation only and the skins are not returned to the lime liquor as is the case in Europe, the problem of swelling the skin in subsequent liquors in order to loosen the fibre plays no part. After depilation "they are allowed to dry for a day," when they are ready for bating. This repeated reference to drying appears to be the natives' method of sterilising the skin between operations while the skin is in the pelt condition.

For tanning purposes the chief agent throughout Nigeria are the pods of the *Acacia arabica*. The bark, which possesses a much lower tannin content, does not appear to be used. In Somaliland tanning is carried out entirely with the native tanning barks and leaves, and the

three commonly used for this purpose and recognised as the best are, in the order of their superiority, the leaves and tender young branches of the watta bush (*Osyris abyssinica*), the *thai*, or bark of the root of a species of acacia known as galol, and the bark of another acacia called marra.

The concluding section of the article deals with the dyeing of Nigerian leather, and describes the methods by which the natives obtain the beautiful reds and greens for which their leathers are famous.

THE PRODUCTION OF EAU-DE-COLOGNE.

One of the chief exports from the city of Cologne to France, Russia, England, and various other countries is eau-de-Cologne. It is also the most popular and most widely used perfume in Germany. There are two stories of the origin of eau-de-Cologne, one being that Giovanni Maria Farina, who was born in 1685, at Santa Maria Maggiore, Italy, first started its commercial manufacture, and the other that John Paul de Feminis, who lived near Santa Maria Maggiore and married into the Farina family, first made it. At any rate, several families named Farina lived at Santa Maria Maggiore and knew the secret of making perfumery, and the secret, according to a widespread tradition, was imparted to a member of the family by an Oriental. Eau-de-Cologne was first introduced into Cologne through some of the many Italians who opened shops there for the sale of Italian silks, embroideries, works of art, perfumery, etc. One or two of them were so successful in selling eau-de-Cologne, which at that time was called "Aqua della Regina," that they finally gave up their other interests and began manufacturing it in large quantities.

This was at the beginning of the eighteenth century, and, according to the United States Consul at Cologne, in 1740 one Farina opened a branch shop in Paris, where his perfume quickly became popular and acquired the name of eau-de-Cologne As the French Court at that time led the world in fashion, the name became valuable and was retained. So with the manufacturer's name, Farina. Many Italians, who had since become naturalised, at once turned their attention to the manufacture of eau-de-Cologne, and manufacturers who had no one named Farina in their family sent to Italy for a Farina, whom they made a partner, or else admitted into the firm some local man whose name was Farina, so that they could truthfully advertise eau-de-Cologne made by Farina. There are now forty manufacturers of the perfume in Cologne, and no less than twenty have the name Farina.

Until a few years ago there were bitter trade wars between manufacturers, some claiming that others were usurping their names or their label, or the form and shape of the bottle and the packing. This has now been stopped owing to the German law of registration of trade-marks, and each firm has its own distinctive label, even though many are very similar. It is impossible to state the yearly output of eau-de-Cologne. In Germany and France, among other countries, eau-de-Cologne is not only used as a perfume, but it is also believed to have some therapeutic effect in cases of inflammation of the eyes, headache, and toothache, and is even taken internally for indigestion and palpitation of the heart. It is largely used, too, sprinkled in baths and for refreshing the air in sick rooms.

There is no secret of the general process of manufacture. Eau-de-Cologne contains pure alcohol as a base, and from three or four to seven or eight other ingredients, which are essences of fruits and flowers. Lemons and oranges as well as their blossoms are always used, with, of course, other flower essences. Manufacturers state that even though quantitative and qualitative analyses should reveal the ingredients and their amounts, their perfumes could not be copied, as their virtue entirely depends upon the order in which the ingredients are put together. The formulæ of the different manufacturers are most jealously guarded, and only the head of each firm does the actual mixing, the secret being handed down from one generation to the next. The extracts and essences are bought in France and Italy, while the alcohol is manufactured in Germany. The best brands of eau-de-Cologne are stored for varying periods, so that the old bouquets or ethers can develop, just as they do in old wines. Manufacturers who make cheaper grades naturally cannot afford to keep large stocks, and their perfumes are, therefore, necessarily inferior. The general process of manufacture is simple, only a few assistants being needed, except for filling and labelling the bottles and packing. The bottles and corks, as well as the labels and packing materials, are made in Germany and bought from manufacturers.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Industrial Habits.—The industrial habits of textile workers in general are distinctly good, and possibly for that reason very little is heard about them. It should, however, be noticed that nobody accuses any large number of them in the present jealously critical times of allowing drink to interfere with work. It is natural in this connection to assign some importance to the point that in the main industries about 60 per cent. of the employed are women, and some 15 per cent. are young persons in whom sobriety can be expected as a matter of course. Yet it cannot be said that the good record is dependent upon their influence or number. The departments staffed by women and young people are officered by men, and upon their punctuality and steadiness regularity and

efficiency depend. Then it is the case that good timekeeping is overwhelmingly the rule in the branches worked solely by men. Where irregularity is most marked there are familiar contributory circumstances. Where employment is intermittent, where men are engaged by the day or the half-day, and still more where they are engaged for the night, attendance at work is not uniformly good. The work of these casuals being unskilled, and sometimes unpleasant and exhausting, a certain irresponsibility is not to be wondered at. Relatively to the whole body these men are few, their employment is restricted to particular branches and districts, and their traditions are less respectable than those of the rest.

Women and Men.—The fact that men are the officers and non-commissioned officers of departments in which women and young people form the rank-and-file has its importance in another connection. Those managers, overlookers, and loom-tacklers could not be removed bodily into military training without throwing the employment of women into chaos. Their functions are in part executive, but it can hardly be said that there are women ready equipped to take over that part of the duty. Some of the tasks involve bodily strain, as in the setting of machines, although the exertion is not always severe. The visibly effective barrier to the substitution of women for men in these posts is a twofold one. A nice understanding of machinery is required, such as is to be obtained only by experience; and the women in closest contact with the machines are generally ill-educated and without mechanical knowledge or knack. These may be the reasons why women have scarcely displayed so much as a symptom of ability to replace men in the higher branches of mill work. Men adjust the machines which women mind, but there are also male machine-minders—for example, weavers—employed mainly on heavier or more complicated work than that done by women. In many mills there are employments which are men's jobs rather by custom than by necessity, and in a few of them men have ousted women, although usually the process has worked the other way about. These considerations, complicated by union rules and employers' preferences, make the drafting of men out of industrial occupations into military work one of some considerable difficulty, and necessitate the conferences that are now being held in which employers, operatives, and Government officials are taking part.

The Natural Dyes.—The imminent shortage of dyestuffs begins to weigh more heavily on the minds of dyers, but it is not clear that the prospects have done much to stimulate sales of white or cream-coloured goods for the summer. Larger quantities than usual of the old-fashioned dyewoods and extracts are palpably being used, but the increase upon this hand does not compensate for the decrease in the receipts of the artificial colours. Evidently there are still misapprehensions abroad as to the relative merits of such dyes as can be extracted from plants and the coal-tar colours. A recent question in Parliament spoke of the former as fast and superior, but these are not claims that can be maintained. The natural colours are in general less bright than the artificial, but nothing is easier than to sadden a bright colour to any desired degree of dullness. The advantage of fastness lies incontestably with the artificial colours, but in the eyes of any dyer the supreme advantage of the latter consists in their ease of application and the certitude with which a required shade can be produced. Leaving aside the cost of the colour stuff, the cost of applying the tar dye is enormously less, and, apart from any other consideration, this suffices to put several theoretically eligible materials altogether out of practical account

Swiss Patent Law.—The normal output of the Swiss colour factories is calculated to be about one-twelfth of the German. Evidently they delivered little to this country during March, and, indeed, the total receipts of foreign tar dyes during this year average only the small amount of ninety tons per month. The obtaining of Swiss supplies is understood to be contingent in part upon the supply of intermediate products from this country. Apart from the temporary aspect, it is pertinent to inquire why a small country with a small internal consumption of colours has a relatively large colour-making industry; all the more so because larger countries with larger needs have failed to acquire a colour industry of any appreciable size. It is, perhaps, not generally known that, until a few years ago, nothing was patentable in Switzerland which could not be represented by a model. In effect there were no patents obtainable for chemical processes or products, and there was consequently nothing to stop Swiss manufacturers from making use of any processes of which they could gain particulars. The hiatus had its useful results, but it is to be inferred that also it had its disadvantages. At any rate, Swiss law was amended to make the patenting of processes and products practicable.

German Substitutes.—The trouble of getting a sufficiency of jute fabric has led the British Government to adopt a coarse cotton cloth for the making of sandbags. Cotton canvas has in several directions been substituted for flax, and with the variety and quantity of fibres at disposal there need be no doubt that all requirements can be effectively met. A German journal shows that the enemy is using "*Stranfa*"—a product of straw—in place of jute for forage

bags, but the substitute does not serve for meal, presumably because the powder leaks through the interstices. The German civil public has been adjured to use the same material as far as possible. The substitute is clearly only a partly efficient one, like the other German substitutes that have been tried. It may be recalled that German sacks, made half of jute and half of twisted paper, were responsible for the bursting loose of a whole ship's cargo not many years ago. For reasons not specifically stated, the German Association of Hemp Manufacturers have given a conditional guarantee to buy all the hemp that farmers in Germany can produce, and they have undertaken to sell seed to the growers at about half the market price. The German cotton-finishing industries have been placed in an awkward position by the refusal of the Government to allow starches to be used for the stiffening of cloth.

The Transference of Business.—The worsted industry is experiencing marked benefit from the cessation of Continental competition. Orders are being received for large quantities of the dry-combed merino tops which are one of the special products of the German combing mills; for merino yarn that would normally have been bought from Germany; and for merino dress goods. In a less direct manner the sale of such British specialities as mohair and alpaca is being stimulated. By the time that military requirements have been met to the full the embargo upon the export of the stronger wools and the yarns made from them should be removed. When that obstacle is out of the way a strong impetus to the sales of the prime British speciality ought to follow. A continually increasing proportion of woollen and worsted machinery is being diverted to private trade, and although the profits of trading are nothing like equally distributed, the prospects may be regarded as good.

An Industrial Guide.—The chances are that any set of data compiled for his own reference by one man would have their utility to a considerable number of others. A pocket-book, preserving facts and figures for reference, was the foundation of Mr. S. Ecroyd's "Cotton Year Book" (Marsden, Manchester, 2*s.* 6*d.*), now in its tenth year of issue. The contents have less to do with raw cotton and cotton movements than the title might seem to suggest, although the operations of the cotton market are very lucidly described. The main preoccupation is with the machines on which cotton is manufactured, and their functions, features, systems, and relations one to another are set forth most systematically. The outcome is a kind of *catalogue raisonné*, a catalogue of no one firm, embracing impartially virtually every machine used for cotton. For ready reference such a book is both handier and less confusing than treatises in which the intricacies are explored at more length, and of essential practical matter it contains as much as a shelf of books, with the advantages of a compact form and an orderly arrangement. Perhaps "Guide Book" would be a more correct name for it than "Year Book," and to all the highways and most of the byways, and to most of the surrounding country, the volume makes a valuable and unique guide.

OBITUARY.

Sir James Rankin, Bt.—The death of Sir James Rankin took place at his residence at Bryngwyn, Herefordshire, on the 19th inst. He was born in 1842, and was educated at Trinity College, Cambridge, where he obtained a first class in the Natural Sciences Tripos. He entered the House of Commons in 1880, as Conservative M.P. for Leominster; the borough was disfranchised by the Reform Bill in 1885, and from 1886 to 1906, and again from 1910 to 1912, he represented North Herefordshire. He was created a baronet in 1898. For some years, 1877–84, he was Master of the South Herefordshire Hounds.

Sir James took a deep interest in various social questions, and published papers on Old Age Pensions, Housing of the Poor, and kindred subjects. In 1883 he read a paper on "The Duty of the State towards Emigration," for which he received the Society's silver medal. He became a member of the Royal Society of Arts in 1877.

Sir Charles Seely, Bt.—Sir Charles Seely died suddenly from heart failure, after an attack of influenza, on the 16th inst., at his residence, Brooke House, Isle of Wight.

He was born in 1833, the son of the late Mr. Charles Seely, a well-known coalowner and for many years Liberal member of Parliament for Lincoln. Sir Charles was elected M.P. for Nottingham in 1869, and continued as one of the representatives of the constituency till 1874, and again for the periods 1880–85 and 1892–95. After the introduction of the Home Rule Bill, he was among the Liberal members who seceded.

Sir Charles was a keen supporter of the Volunteer movement, and for eighteen years was Colonel of the Robin Hood Rifles. He was created a baronet in 1896. He was a generous benefactor to Nottingham, and also to the Isle of Wight, where he was a large landowner. His third son, Brigadier-General John Seely, was for some years Secretary of State for War.

Sir Charles was elected a member of the Royal Society of Arts in 1871.

NOTES ON BOOKS.

The Indian Year Book, 1915. Edited by Stanley Reed, LL.D. London, Bombay, and Calcutta: Bennett, Coleman & Co., Ltd.

When this "Whitaker of India" made its first appearance last year it received a warm welcome, and a large edition was exhausted within three months. There can be little doubt that this welcome will be extended to the second issue, and that the better it becomes known the wider and deeper will be the public appreciation of it. For it contains an immense mass of information, not readily obtainable from other sources, dealing with all aspects of Indian life.

The principal new feature of the second issue is a review of the proceedings of the Legislative Councils. In the case of the Imperial Legislative Council this has been made as complete as possible, and covers eleven pages of very small type; the accounts of the Provincial Councils are naturally briefer. The splendid part which India has played in the great war is also well described in a special article, and the volume is enriched by an excellent map of the Indian Empire.

It is quite impossible within reasonable limits to give any account of the multifarious subjects treated in the Year Book. Suffice it to say it is packed full of information which should prove of great service to politicians, statisticians, geographers, economists—indeed, to all who take an interest in India; and it should find a place along with the classic works of reference in every club and public library.

GENERAL NOTES.

Professional Classes War Relief Council.—A grand patriotic concert will be given at the Royal Albert Hall to-morrow afternoon (the 24th inst.) at 3 p.m. in aid of the funds of this council and of the Lord Mayor's recruiting bands. Among the artists will be Miss Ruth Vincent, Miss Lily Elsie, Madame Kirkby Lunn, Mr. Ben Davies, and Madame Tita Brand. The massed recruiting bands and the Coldstream Guards' band will also play.

Chinese Conservancy Engineering College.—An institution has been established at Nanking for the study of conservancy engineering. It is under the control of the National Conservancy Bureau, and its expenses are paid by the provinces of Chihli, Shantung, Kiangsu, and Chehkiang. The school has as its object to train engineers for conservancy work. The whole course covers four years—one year in the preparatory school and three years in the college. For the purpose of meeting requirements for the conservancy work of the Huai River a special course is given. This course covers two years of the study of important subjects. The requirements for entrance examination are Chinese essay, English, algebra, plane and solid geometry, chemistry, and physics. With the exception of the students coming from the four provinces supplying funds to the institution, those who come from the other provinces will have to pay a yearly tuition fee of $40 in addition to boarding expenses. Students after graduation are liable to serve a certain period in the National Conservancy Bureau.

The World's Shipbuilding.—According to the annual summary issued by *Lloyd's Register of Shipping*, during 1914, 656 vessels, of 1,683,553 tons gross, were launched in the United Kingdom. The output of mercantile tonnage shows a decrease of 248,600 tons on that of the previous year, which was the highest ever reached. Of the total output, 75⅝ per cent., or 1,273,530 tons, has been built for registration in the United Kingdom. The amount of tonnage launched for other countries during 1914 was 410,023 tons, forming 24⅓ per cent. of the total output, as compared with over 21½ per cent. in 1913, nearly 24 per cent. in 1912, 22⅓ per cent. in 1911, 19½ per cent. in 1910, 24⅔ per cent. in 1909, 40 per cent. in 1908, and 34 per cent. in 1907. The Clyde district occupies the first place among the shipbuilding centres of the country, showing an output of 444,621 tons (Glasgow 288,103 tons and Greenock 196,518 tons). Then follow the Tyne (315,585 tons), the Wear (277,528 tons), Belfast (239,819 tons), Middlesbrough (137,165 tons), and Hartlepool (124,419 tons). Of the vessels launched in the United Kingdom during the year, two steamships, with a total tonnage of 13,618 tons, were built for Japan, against one vessel in each of the two preceding years. With regard to the output of other countries, it is noted that the tonnage launched in Japan during the year (85,861 tons) is nearly 33 per cent. higher than the output for 1913, and exceeds all previous totals. It comprises three steamers of between 11,000 and 12,000 tons each, and one steamer of 7,345 tons, fitted with geared turbine engines. The remainder of the total is composed of vessels of small tonnage, of which 26 vessels (51,038 tons), were built at Kobé and Osaka, five vessels (32,623 tons) at Nagasaki, and one (2,200 tons) elsewhere in Japan.

Ground-nuts.—Under the auspices of the Imperial Institute serious attempts are being made to create a market in this country for the ground-nuts grown in India and the British Colonies, such as Gambia and Nigeria, and inquiries are invited for information on the culinary uses to which they can be put. As a food for cattle, the flesh-forming value of the ground-nut has long been recognised, but in this country, at all events, it has not been seriously considered as an article of food. In the United States of America the nuts are eaten roasted, as well as in the form of "pea-nut butter," a paste made by grinding the blanched kernels. In West Africa the kernels are regularly used as a vegetable, chiefly in the form of soup, though they are also served in a variety of other ways, and in France a good deal of what is sold as olive oil really hails from South Indian ground-nuts.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

April 28. — A. S. E. Ackermann, B.Sc. (Engineering), Assoc.M.Inst.C.E., "The Utilisation of Solar Energy." Charles Vernon Boys, F.R.S., will preside.

May 5. — Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., "On the Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate." Francis William Goodenough, M.Inst. Gas Engineers (Gas Light and Coke Co.), will preside.

May 12.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry." Sir Robert Abbott Hadfield, D.Sc., F.R.S., will preside.

Additional Lecture.

Thursday afternoon, at 4.30 o'clock:—

May 6.—M. Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Constantin Meunier et les Sculpteurs Belges de son Temps." Lord Sanderson, G.C.B., K.C.M.G., will preside.

Indian Section.

Thursday afternoon:—

May 13, at 4.30 p.m.—Sir Charles H. Armstrong, late Chairman, Bombay Chamber of Commerce, "Indian Trade and the War." The Most Hon. the Marquess of Crewe, K.G., P.C., Secretary of State for India, will preside.

Colonial Section.

Tuesday afternoon, at 4.30 o'clock:—

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials." The Hon. Sir George H. Perley, K.C.M.G., Member of the Canadian Government, will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

David Sommerville, B.A., M.Sc., M.D., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Syllabus.

Chemical Constitution of Foodstuffs—Proteins—Carbohydrates — Fats — Inorganic Substances — Colloids and Crystalloids—Metabolism—Enzymic Action in the Alimentary Canal.

MEETINGS FOR THE ENSUING WEEK.

Monday, April 26...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. D. Sommerville, "Foodstuffs." (Lecture I.)

Medicine, Royal Society of, 1, Wimpole-street, W. Section of Odontology, 8 p.m. 1. Discussion on Dr. E. Waller's paper, "The Influence of the Thyroid Gland on Dental Caries." 2. Dr. J. S. Wallace, "The Principles of Dietetics."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Discussion on paper by Messrs. C. S. Joseph and R. S. Gardiner, "The Report of the Land Enquiry Committee on Housing."

Geographical Society, Burlington - gardens, W., 8.30 p.m. Mr. D. G. Hogarth, "Geography of the War in the Near East."

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Mr. G. King, "The New National Life Tables."

Tuesday, April 27...Sociological Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.15 p.m. Mr. G. P. Gooch, "German Theories of the State."

Illuminating Engineering Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Messrs. C. C. Paterson and B. P. Dudding, "Visibility: its Practical Aspect."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. B. Fletcher, "The War on Belgian Architecture." (Lecture III.)

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. Annual General Meeting.

Photographic Society, 35, Russell - square, W.C., 8 p.m. Mr. E. Marriage, "The Carvings on Amiens Cathedral."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. A. Dickinson, "The Bombay Hydro-Electric Scheme."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Mrs. Rose Haig Thomas, "White Collar Mendelising in Hybrid Pheasants." 2. Mr. E. G. Boulenger, "On Two New Tree-Frogs from Sierra Leone, recently living in the Society's Gardens." 3. Messrs. E. Heron-Allen and A. Earland, "The Foraminifera of the Kerimba Archipelago (Portuguese East Africa." (Part II.)

Wednesday, April 28...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. A. S. E. Ackermann, "The Utilisation of Solar Energy."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7.30 p.m. Mr. A. Dickinson, "The Bombay Hydro-Electric Scheme."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 5 p.m. Dr. W. P. Norris, "The Evolution of Hygiene and Public Health in Australia."

Thursday, April 29...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle - street, W., 3 p.m. Dr. A. W. Porter, "Advances in General Physics." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. E. Marriage, "Amiens Cathedral."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. A. Dickinson, "The Bombay Hydro-Electric Scheme."

Friday, April 30...Petroleum Technologists, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. W. Calder, "Oil Well Engineering."

Royal Institution, Albemarle-street, W., 9 p.m. Professor F. G. Donnan, "Emulsions and Emulsification."

Saturday, May 1...Royal Institution, Albemarle-street, W., 3 p.m. (Tyndall Lecture.) Professor J. A. Fleming, "Photo-Electricity." (Lecture I.)

5 p.m. Annual Meeting.

Journal of the Royal Society of Arts.

No. 3,258. VOL. LXIII.

FRIDAY, APRIL 30, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 3rd, 8 p.m. (Cantor Lecture.) DAVID SOMMERVILLE, B.A., M.Sc., M.D., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, "Foodstuffs." (Lecture II.)

TUESDAY, MAY 4th, 4.30 p.m. (Colonial Section.) S. CHAS. PHILLIPS, M.S.C.I., "The Empire's Resources in Paper-making Materials." The HON. SIR GEORGE H. PERLEY, K.C.M.G., Member of the Canadian Government, will preside.

WEDNESDAY, MAY 5th, 8 p.m. (Ordinary Meeting.) AUGUSTUS VERNON HARCOURT, D.C.L., LL.D., D.Sc., F.R.S., "On the Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate."

THURSDAY, MAY 6th, 4.30 p.m. (Special Lecture.) M. PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Constantin Meunier et les Sculpteurs Belges de son Temps." LORD SANDERSON, G.C.B., K.C.M.G., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

HONORARY ROYAL FELLOW.

The Council have the pleasure of announcing to the Fellows that His Majesty the King of the Belgians has graciously consented to allow his name to be added to the List of Honorary Royal Fellows.

His late Majesty King Leopold was one of the first two Honorary Royal Fellows elected in 1876, the other being His late Majesty the King of Sweden and Norway.

The other Royal Honorary Fellows of the Society are: The King of Spain (1905), The King of the Hellenes (1906), The King of Norway (1906), The King of Sweden (1908), The King of Portugal (1909), The Emperor of Russia (1909), and The King of Denmark (1914).

CANTOR LECTURES.

On Monday evening, April 26th, DR. DAVID SOMMERVILLE, B.A., M.Sc., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, delivered the first lecture of his course on "Foodstuffs."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 28th, 1915; CHARLES VERNON BOYS, F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Balls, William H., Southern High School, Broad and Jackson-streets, Philadelphia, Pennsylvania, U.S.A.

Heath, Principal Lionel, I.E.S., Mayo School of Art, Lahore, Punjab, India.

Lau Chu Pak, Hon., J.P., 1, Babington-path, Victoria, Hong-Kong, China.

Stanley, William, Great Barrington, Massachusetts, U.S.A.

Turner, Walter V., Edgewood Park, Pittsburgh, Pennsylvania, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Best, William Newton, M.Am.S.Mech.E., 11, Broadway, New York City, U.S.A.

Higman, Ormond, M.I.E.E., Electrical Standards Laboratory, Ottawa, Canada.

Jairazbhoy, Cassamally, Warden-road, Bombay, India.

Khan, Sahebzada Abdussamad, C.I.E., Chief Secretary, Rampur State, Rampur, United Provinces, India.

Mellor, Alfred, 152, West Walnut-lane, Germantown, Philadelphia, Pennsylvania, U.S.A.

Ram, Atma, Civil Lines, Ludhiana, Punjab, India.

Rumbough, John B., Enterprise Machine Company, 67–71, North Main-street, Asheville, North Carolina, U.S.A.

Smith, Miss Alice Maude, M.D., Chicago State Hospital, Dunning, Illinois, U.S.A.

Wilder, Gerrit Parmile, care of Hawaiian Trust Company, Ltd., Honolulu, Hawaii.

Wilder, Leonard H., Ingleside, near McLean, Virginia, U.S.A.

The paper read was—

THE UTILISATION OF SOLAR ENERGY.*

By A. S. E. Ackermann, B.Sc. (Engineering), A.C.G.I., M.Cons.E., A.M.Inst.C.E.

As it has been justly said that the play of "Hamlet" without the Prince of Denmark is somewhat dull, perhaps it will be well to devote a few words to the principal actor in all schemes for the utilisation of solar energy, viz., the sun. He is no longer regarded as a monster fire, burning in the manner of fires in our grates. Great as is his mass, it would be comparatively rapidly consumed if such combustion were taking place. Another reason why this old idea was given up is, that the temperature of the sun has been determined by several experimenters, and all agree that it is about 6,000° C. This is far too high to permit of the formation of most chemical compounds, and for the production of heat by combustion it is necessary for such compounds to be formed. Briefly, such a temperature decomposes nearly all compounds into their elements and prevents their re-uniting and the consequent production of heat.

Scientists are by no means certain how the sun's heat is produced, but one theory is that it is due to radio-activity, and another, due to Helmholtz, that the energy to keep up the radiation could be supplied by a relatively microscopic contraction of the sun's volume, though even this theory is not a complete success, as it implies that the age of the sun is 17,000,000 years. Great as is this lapse of time, geology indicates that our earth is considerably older; but as the earth cannot very well be older than the sun, we must conclude that the sun is older than 17,000,000 years.

As to what the structure of the sun is, there is also doubt; but the inner portion is spoken of as the nucleus, and the outer portion as the atmosphere, and as the outer layers of the atmosphere get relatively cooled they sink to a lower level, and their place is taken by hotter layers. Thus there is a continual circulation of the sun's atmosphere.

The specific gravity of the sun is only about a quarter of that of the earth, whose specific gravity is 5·53. A cubic foot of water weighs 62½ lb., and hence an average cubic foot of the sun weighs 86¼ lb., while an average cubic foot of the earth weighs 345 lb. For comparison, it may be mentioned that a cubic foot of granite weighs 165 lb. The density of the sun being so small, it is concluded that it can still go on contracting, and hence that it is probably getting hotter instead of cooler, as is popularly supposed. If this be so, it is a hopeful feature for future workers in the field of solar energy.

The diameter of the sun is 863,600 miles, or about one hundred times the diameter of the earth, and an earthly pound weight at its surface would weigh 27½ lb. The glowing surface which the sun presents to us, even considering him as a flat disc, has the enormous area of 585,750,000,000 square miles, each square foot of which emits the enormous amount of about 12,500 h.p., and the radiant energy received at the outer surface of the earth's atmosphere is equivalent to 7,300 h.p. per acre. Of this about 70 per cent. (say, 5,000 h.p. per acre) is transmitted to the land surface of the earth at noon on a clear day, and less in the morning and evening, owing to the greater thickness of atmosphere through which the radiation has to pass.

The quantity of solar heat per unit area which arrives in unit time at the outer surface of our atmosphere is called the solar constant, and its value, as determined in 1913 by C. G. Abbot, of the Smithsonian Institution, after making 696 experiments in different parts of the globe, is 1·93 calories per sq. cm. per min. (= 7·12 B.T.U. per square foot per minute). Its value given by various experimenters between 1881 and 1909 was considerably higher, and this makes it all the more remarkable that John Ericsson, the engineer and inventor who spent some £20,000 on experiments with solar energy, when writing in 1876 a record of his life's work, gave the value of the solar constant as 7·11 B.T.U. per square foot per minute, and said, "In view of the completeness of the means adopted in measuring the energy developed, and the

* The right of reproduction is reserved.

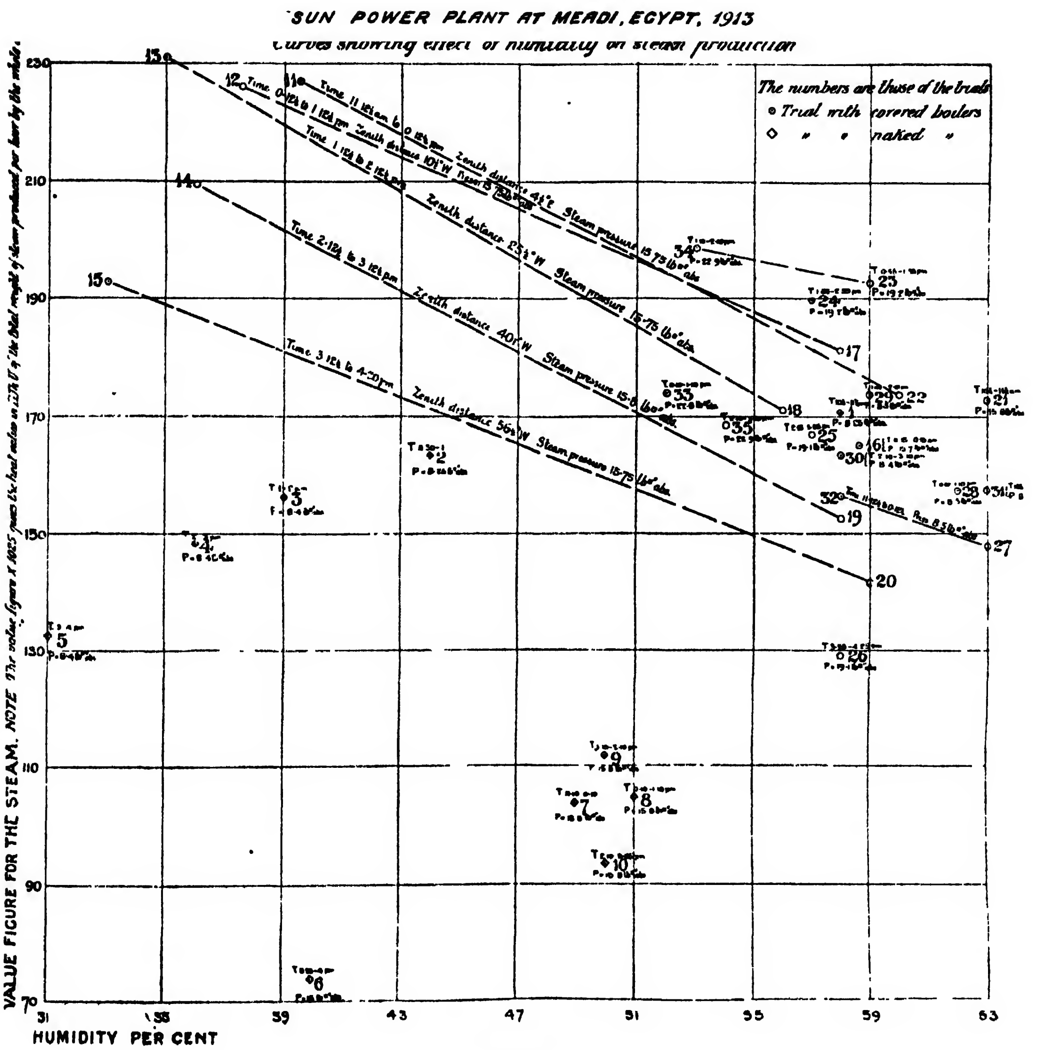


FIG. 1.

ample time which has been devoted to the determination of the maximum intensity, it is not probable that future labours will change the result of our determination," and, as shown above, his confidence was justified.

Perhaps the most remarkable things about solar radiation are that it passes through the 93,000,000 miles (one million is 2,740 a day for a year) of space between the sun and the earth, the temperature of which is nearly absolute zero (*i.e.*, it is about $-263°$ C.), and that only three-fifths of it produces any impression on the eye. It is not till the radiant energy impinges on some material body that it is converted into heat. The best body for causing such conversion is a dead-black one.

The absorption of solar energy by the atmosphere is about 20 per cent. greater in summer than in winter. This may be due to there being a larger total quantity of water vapour in the atmosphere in summer than in winter. It has long been known that the greater the humidity of the atmosphere the greater the amount of heat stopped by it; but the author believes that his experiments in Egypt in 1913, with the Shuman-Boys sun-power plant, were the first which determined the quantitative effect of humidity, especially on so large a scale. The curves on Fig. 1 record the results, from which it is seen that when the humidity decreased 20 per cent. the quantity of steam increased about 30 per cent., thus showing the great importance of humidity in connection with this subject.

The great possibilities of this field of work, and the obvious fact that there is a limit to our supplies of coal and oil, have naturally attracted many workers, of whom the following is a chronological list. Some of them, however, have not been engaged in the practical utilisation of solar energy, but in determining the solar constant and atmospheric absorption which tell us the theoretical quantity of heat available for power purposes.

Name.	Date of Birth.	Date of Death.	Date of first Solar Work.
Solomon de Caux (France)	1576	1626	1615
H. B. de Saussure (Sweden)	1740	1799	1766
Sir John Herschel (England)	1792	1871	1836
C. S. M. Pouillet (France)	1791	1868	1838
C. L. Althans (Germany)	(?)	(?)	1853
Carl Güntner (Austria)	(?)	(?)	1854
August Mouchot (France)	(?)	(?)	1860
John Ericsson (U.S.A.)	1803	1889	1864
C. H. Pope (U.S.A.)	(?)	(?)	1875
William Adams (England)	(?)	(?)	1876
Abel Pifre (France)	(?)	(?)	1878
S. P. Langley (U.S.A.)	1834	1906	1881
J. Harding (England)	(?)	(?)	1883
Chas. Louis Abel Tellier (France)	(?)	1913	c. 1884
A. G. Eneas (U.S.A.)	(?)		1900
H. E. Willsie	(?)		1902
C. G. Abbot (U.S.A.)	1872		1905
Frank Shuman (U.S.A.)	1862		1906
Ch. Féry (France)	1865		1906
G. Millochau (France)	1871 (?)		1906

Now, although the theoretical power value of the heat reaching the surface of the earth is no less than 5,000 h.p. per acre, it must not be thought that anything like this amount can be converted into mechanical power, any more than can all the heat of coal be converted into its theoretical equivalent of mechanical power. For example, the heat value of good coal is about 14,500 B.T.U. per lb. = 12,760 h.p. hours per ton, but in fact the best result, even under test conditions, ever obtained from a ton of coal by means of a boiler and steam engine is only about 1,470 b.h.p. hours, or 11·5 per cent. of the heat value, while in the case of a gas engine the corresponding figure is 25·5 per cent., and of a Diesel oil engine 31 per cent. The chief loss is in converting the steam into mechanical energy, and most of the loss is inevitable for thermodynamic reasons. With this fact in mind, you will not be so surprised to learn that the best overall thermal efficiency obtained from the Shuman-Boys plant in Egypt was only 4·32 per cent., the chief reasons for this being so much less than 11·5 per cent. being that the steam pressure was so low, and that the best efficiency of the sun-heat absorber was only 40·1 per cent., compared with 75 per cent. for the best coal-fired boiler. But it has taken boilermakers many years to attain this efficiency, so that 40·1 per cent. is not a bad result when the number of sun-boilers that have been made is taken into account. Thermal efficiencies of engines are materially affected by the heat-fall of the steam, just as the efficiencies of water

turbines are affected by the height of the waterfall. The larger the fall in either case the better the efficiency.

It is interesting to realise from the foregoing figures that the value of 2½ acres of bright sunshine for an hour is one ton of coals. This fact is more readily realised in Egypt in the summer. With this we may compare what Mr. J. C. Hawkshaw said in his presidential address to the Institution of Civil Engineers in 1902, viz., that the wood fuel produced by an acre of land in Europe is equivalent to at least one ton of coal a year.

With so much heat generated at the surface of the earth it might be thought that the temperature of the earth would rise. So it would do, were it not for the fact that the earth radiates into space as much heat as it receives, though some of it may be stored on earth for a time in the form of vegetable growth (including coal) or water raised to high levels.

Coal has been called "bottled sunshine," but the cork of the bottle must be a leaky one, for Abbot says ("The Sun," p. 360): "It appears from such investigations as have been made that plants may store up as chemical energy in round numbers 1 or 2 per cent. of the energy of solar radiation which shines upon their leaves." With regard to the earth's own heat, it has been estimated that the continuous supply coming from the interior to the surface is equivalent to 1,280 h.p. per square mile, or only 2 h.p. per acre.

Having now considered the nature of the source and the quantity of heat available, we will give a brief description of the plants which have been constructed by various experimenters for the purpose of utilising solar heat. They are given in chronological order as regards their solar work so far as the author has been able to discover the facts.

At one stage the author thought he had discovered the earliest worker at the subject when he came across a record of Sir John Herschel's experiments in 1836, but further research disclosed that Buffon, the celebrated French naturalist, was at work in 1747, and on April 10th of that year he succeeded in setting fire to a plank of tarred wood, at a distance of 150 ft., by solar rays reflected from a combination of flat mirrors. He did this to show the possibility of the legend that Archimedes set fire to the fleet of Marcellus at Syracuse in 212 B.C.

Other early workers were Roger Bacon, an English Franciscan monk, who died in 1294; Solomon de Caux (1576–1626), a French engineer, who in 1615 invented and described the first machine for raising water by solar heat and the expansion of air; Ducarla; and H. B. de Saussure, the Swiss geologist, physicist, and naturalist, who made (in 1787) the second ascent of Mont Blanc. To de Saussure the credit is due for inventing the "hot box" (*i.e.*, an insulated air-tight wooden box, black inside, and covered with two layers of plain glass with an air space between them), which has since been such a favourite with other workers. It was he, too, who found that a cover of two sheets of glass gave the best results.

Next in the field was Sir John Herschel, F.R.S., who in 1837 took the temperature of the surface soil near Cape Town, and for dry earth recorded temperatures varying from 120° F. to 162° F., the latter having been obtained on December 1st, 1837, at 0.36 p.m., in a sand heap sheltered from the wind in a small garden enclosure, the soil being moist 3 ins. or 4 ins. below the surface.

He also experimented with "a small mahogany box, blackened inside, covered with window-glass fitted to size, but without putty, and simply exposed perpendicularly to the sun's rays." In this box he recorded a temperature of 152° F., but "when sand was heaped round the box to cut off the contact of cold air, the temperature rose on December 3rd, 1837, to 177° F. And when the same box, with its enclosed thermometer, was established under an external frame of wood well sanded up at the sides, and protected by a sheet of window-glass (in addition to that of the box within), the temperatures attained on December 3rd, 1837, were—

Time.	Temperature.
1.30 p.m.	207·0° F.
1.50 „	217·5
2.44 „	218·0

and that with a steady breeze sweeping over the spot of exposure. Again on December 5th, under a similar form of exposure, temperatures were observed—

Time.	Temperature.
0.19 p.m.	224° F.
0.29 „	230
1.15 „	239
1.57 „	248
2.57 „	240·5

"As those temperatures far surpass that of boiling water, some amusing experiments were made by exposing eggs, fruit, meat, and in the same manner (December 21st, 1837, *et seq.*), all of which, after a moderate length of exposure, were found perfectly cooked—the eggs being

rendered hard and powdery to the centre; and on one occasion a very respectable stew of meat and vegetables was prepared, and eaten with no small relish by the entertained bystanders."

Sir John then described his method of determining the solar constant by means of a tinned iron vessel 3⅝ ins. diameter, and 2·4 ins. high filled with inked water, upon which he allowed the nearly vertical rays of the sun to play through a 3·024 ins. diameter hole for ten minutes and noted the rise in temperature, of course allowing for cooling losses. The mean of six experiments, made between December 23rd, 1836, and January 9th, 1837, inclusive, gave a rise of 0·38° F. per minute, the quantity of water being 4,638 grains. Allowing for the obliquity of the sun's rays, the mean area of the normal cross-section of the beam of sunlight was 7·01 sq. ins. From these particulars we are able to calculate that Herschel's value of the solar radiation reaching the earth's surface was 1·38 calories sq. cm. min., while if we assume the coefficient of atmospheric transmission to have been 0·70, his value of the solar constant was 1·98, agreeing well with 1·93, the value now accepted as correct.

From these experiments he deduced that a cylindrical rod of ice, 45·3 miles in diameter, and of indefinite length, continually darted into the sun with the velocity of light (186,000 miles per second), would barely suffice to employ the whole radiant heat for its fusion, without at all reducing the temperature of the sun.

For comparison with Herschel's sand temperatures recorded above, the author gives the following similar readings which he obtained at Meadi, Egypt.

Date.	Time.	Reading of Thermometer under Loose Lamp-black and Sand.	Reading of Thermometer under Ordinary Sand.	Thermometer with Blacked Bulb lying on Sand.	Shade Temperature.	Humidity per Cent.	Wind. Velocity in Miles per Hour.	Wind. Direction.

Almost contemporaneous with the work of Herschel was that of Mons. C. S. M. Pouillet, a record of which, on the determination of the solar constant, appears in *Comptes Rendus*, Vol. VII., 1838, pp. 24–65. His value of the solar constant was 1·763 calories sq. cm. min.

Carl Güntner was at work experimenting with reflectors in Laibach in 1854, and in 1873 he exhibited one at the Vienna Exposition. Güntner wrote in the *Scientific American Supplement* of May 26th, 1906, pp. 25, 409–412:

"This reflector possessed, however, the disadvantages common to all sheet-metal reflectors, that to maintain the surface in proper condition when exposed to all sorts of weather requires careful and costly attention.

"Being convinced, however, that the exploitation of solar heat will come more and more into vogue, even in spite of the disadvantageous periodicity of this source of warmth, I have taken the trouble to put aside the evil mentioned above, and overcome it by an entirely new method of reflector construction . . . This plane reflector consists of a large number of long, narrow mirrors placed at suitable distances from one another, and which, when upon level ground, lie parallel with each other horizontally, extending either from north and south or from east to west.

"Each one of these mirrors revolves about a horizontal axis, and by means of a simple parallelogram motion may be made to follow the sun in such a manner that all the sun's rays falling upon the plane mirrors may be reflected on the surface of a tube or boiler, the long axis of which lies also in the plane of the mirror axis . . . by a simple movement of a hand lever, all the mirrors may be simultaneously turned through an arc of 180°, which means that all the mirrors may thus be made to look towards the ground, and be in this way protected from the destructive action of sudden falls of hail."

He claimed that the reflector could be made at a cost of 8*s.* 6*d.* per square yard of reflecting surface, and that it required "but 200 square feet of surface to generate steam sufficient for one horse-power." He proposed to construct the reflectors of thin corrugated steel plates, faced with lead and then coated with tin.

"Hence it is necessary to discover the value of *e* (the amount of useful heat dispensed per unit of surface per minute) which affords the unit of heat that can be made available for effective service from a square foot of catching surface per minute.

"Being deprived of the experience of any former experimenter in this direction, I myself made appropriate trials with reflectors . . . The two opposite sides, each 3 ft. long, of a wood right-angular frame, having a width of 1 ft. and a length of 3 ft., were hollowed out to correspond with a previously designed parabolic template, and upon the parabolic curve thus established two sheets of white tin were nailed. Four supports, which were fastened to the sides of the frame, carried a 3½-in. tube erected in such a manner that its axis coincided with the burning axis of the reflector . . The catching surface presented a superficial area equal to 3 square feet . . . The boiler was not lagged with glass or anything."

He then gives a table of four tests of one hour each, varying from 9 a.m. to 4 p.m., and goes on to say: "From these experiments it has been deduced that the amount of heat given off per square foot per minute is about $=1\cdot3$ (major) calories ($=1\cdot4$ minor calories sq. cm. min.).

"For our zone [probably Laibach, Austria], then, the mean value of *e* may be set down as $1\cdot3$."

The work of August Mouchot in connection with the utilisation of solar energy was certainly of great importance. It is recorded in his book, entitled "La Chaleur solaire et les Applications industrielles," second edition, 1879; but, as with other workers in this field, he gives extremely meagre information as to results of experiments.

Mouchot started his solar work in 1860, and took out his first patent, No. 48,622, on March 4th, 1861. In the first edition of his above-named work (page 231) he stated that theoretically, on an average, 86 square feet of reflecting surface are required for one horse-power. Then, to allow for losses, he doubled the area, thus making it 172 square feet. It is to be noted that he referred to reflecting surface and not the area of radiation collected, which would almost certainly be a smaller quantity.

On page 195 he described one of his boilers as having a capacity of three and a half pints. It consisted of two cylindrical concentric copper vessels with domed tops and the water space between them. The vertical height of the outer vessel was 16 ins. The boiler was covered by a bell-glass and placed at the focus of a reflector. The water boiled in one hour from an initial temperature of 50° F.

In August, 1866, Emperor Napoleon III. of France saw Mouchot's first solar engine at work in Paris, and in 1872 Mouchot (with the monetary assistance of the French Government) constructed another sun-boiler. This was described by Mons. L. Simonin in the *Revue Des Deux Mondes* of May 1st, 1876, as follows:—

"The traveller who visits the library of Tours, sees in the courtyard in front a strange-looking apparatus. Imagine an immense truncated cone, a mammoth lamp-shade, with its concavity directed skyward. This apparatus

is of copper, coated on the inside with very thin silver-leaf. On the small base of the truncated cone rests a copper cylinder, blackened on the outside, its vertical axis being identical with that of the cone. This cylinder, surrounded as it were by a great collar, terminates above in a hemispherical cap, so that it looks like an enormous thimble, and is covered with a bell-glass of the same shape.

"This curious apparatus is nothing else but a solar receiver—or, in other words, a boiler —in which water is made to boil by the heat-rays of the sun. This steam-generator is designed to raise water to the boiling-point and beyond by means of the solar rays, which are thrown upon the cylinder by the silvered inner surface of the conical reflector. The boiler receives water up to two-thirds of its capacity through a feed-pipe. A glass tube and a steam gauge communicating with the inside of the generator, and attached to the outside of the reflector, indicate both the level of the water and the pressure of the steam. Finally, there is a safety valve to let off the steam when the pressure is greater than desired. Thus the engine offers all desirable safety, and may be provided with all the accessories of a steam-boiler.

"The reflector, which is the main portion of the generator, has a diameter of 2·60 metres at its large, and 1 metre at its small base, and is 80 centimetres in height, giving 4 square metres of reflecting surface, or of insolation. The interior walls are lined with burnished silver, because that metal is the best reflector of the heat-rays; still, brass with a light coating of silver would also serve the purpose. The inclination of the walls of the apparatus to its axis measures 45°. Even the ancients were aware that this is the best form for this kind of metallic mirrors with linear focus, inasmuch as the incident rays parallel to the axis are reflected perpendicularly to the same, and thus give a focus of maximum intensity.

"The boiler is of copper, which of all the common metals is the best conductor of heat; it is blackened on the outside, because black possesses the property of absorbing all the heat-rays, just as white reflects them; and it is enclosed in a glass envelope, glass being the most diathermanous of all bodies, that is to say, the most permeable by the rays of luminous heat. Glass further possesses the property of resisting the exit of these same rays after they have been transformed into dark rays on the blackened surface of the boiler.

"The boiler proper of the Tours solar engine consists of two concentric bells of copper, the larger one, which alone is visible, having the same height as the mirror, *i.e.*, 80 centimetres, and the smaller or inner one 50 centimetres; their respective diameters are 28 and 22 centimetres. The thickness of the metal is only 3 millimetres. The feed-water lies between the two envelopes, forming an annular envelope 3 centimetres in thickness. Thus the volume of liquid is 20 litres, and the steam-chamber has a capacity of 10 litres. The inner envelope is empty. Into it pass the steam-pipe and the feed-pipe of the boiler. To the steam-pipe are attached the gauge and the safety-valve. The bell-glass covering the boiler is 85 centimetres high, 40 centimetres in diameter, and 5 millimetres in thickness. There is everywhere a space of 5 centimetres between its walls and those of the boiler, and this space is filled with a layer of very hot air."

Mechanism was provided whereby the reflector was adjusted by hand to follow the movement of the sun.

"On May 8th, 1875, a fine day, 20 litres of water, at 20° C., introduced into the boiler at 8.30 a.m., produced steam in forty minutes at two atmospheres (30 lb.) of pressure to the square inch, *i.e.*, a temperature of 121°, or 21° above boiling water. The steam was then raised rapidly to a pressure of five atmospheres (75 lb. to the square inch), and if this limit was not exceeded it was because the sides of the boiler were only 3 millimetres thick, and the total effort supported by these sides was then 40,000 kilogrammes. It would have been dangerous to have proceeded further, as the whole apparatus might have been blown to pieces.

"Towards the middle of the same day, with 15 litres of water in the boiler, the steam at 100°—that is to say, at a pressure of one atmosphere—rose in less than a quarter of an hour to a pressure of five atmospheres, equal to a temperature of 153°. Finally, on July 22nd, towards 1 p.m., an exceptionally hot day, the apparatus vaporised 5 litres of water per hour, which is equal to a consumption of 140 litres of steam per minute, and ½ h.p. For these experiments the inventor used an engine which made eighty strokes per minute under a continued pressure of one atmosphere. Later on it was changed for a rotative engine, that is to say, an engine with a revolving cylinder, which worked admirably, putting in motion a pump to raise water, until the pump, which was too weak, was broken."

In 1878 Mouchot used a boiler made of many tubes placed side by side, and having a capacity of 100 litres (70 for water and 30 for steam).

Mouchot seems to have been the only inventor of a solar plant, with the exception of Shuman, who has had his apparatus tested by independent engineers. The following refers to Mouchot's plant. In *Comptes Rendus*, Vol. XCIV. 1882, pp. 943–5, Mons. A. Crova reports that: "The Minister of Public Works appointed two Commissions, one at Constantine and the other at Montpellier, to make experiments with two identical mirrors of 5·22 square metres in section normal to the sun's rays, and to evaluate their practical utility.

"The Commission of Montpellier was composed of MM. Duponchel, Engineer-in-Chief of Ponts et Chaussées, as President; Colonel Fulcrand, R.E.; Guibal, and myself.

"The experiments (at Montpellier) lasted from January 1st to December 31st, 1881, and were made from hour to hour every day during which the sun was bright and the observations possible.

"The solar rays concentrated at the focal line of the mirror were received on a black boiler placed at the axis, and which was enclosed by a glass shade.

"The number of major calories utilised, divided by those incident, received in one hour upon 1 square metre of surface normal to the rays, gives the efficiency of the apparatus.

"Here are the principal results obtained during 176 days which gave 930 observations, during which 2,725 litres of water were distilled.

"MOYENNE GÉNÉRALE DES VALEURS MESURÉES PENDANT L'ANNÉE 1881, ET RAPPORTÉES À 1MQ ET À 1.

	Cal.	Max. Cal.	
Chaleur reçue directement	616·1	945·0	25 Avril.
Chaleur utilisée par l'appareil	258·8	547·5	15 Juin.
Moyenne des rendements	0·491	0·854	14 Juin."

The author has purposely not translated the last nine lines for fear of making a mistake. He is unable to interpret the results, but as they represent an important and independent investigation lasting a year, they are given in the hope that some of his audience may be able to throw some light on the matter.

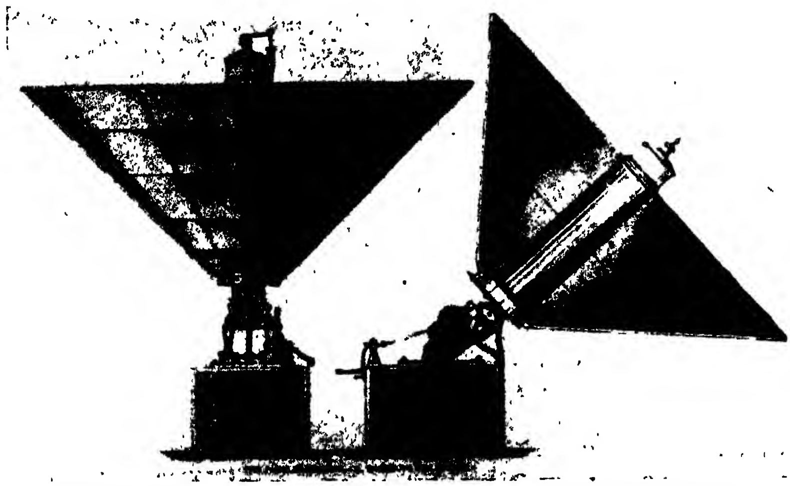

FIG. 2.—MOUCHOT'S MUTIPLE TUBE SUN-HEAT ABSORBER OF 1878.

Next came that versatile engineer and successful inventor, John Ericsson, a Swede by birth and an American by adoption. He made an immense number of experiments, extending over twenty years, with costly apparatus, to determine the solar constant, and later on made apparatus for the practical utilisation of solar radiation. All these experiments were made at his own expense, and he tells us they cost him £20,000, and having done all this work the conclusion he arrived at was: "The fact is, however, that although the heat is obtained for nothing, so extensive, costly, and complex is the concentration apparatus, that solar steam is many times more costly than steam produced by burning coal." (Letter dated September 21st, 1878, to R. B. Forbes.)

We have already referred to his remarkably accurate determination of the solar constant; but he was not so happy in deducing the

temperature of the sun, which he made to be 723,000° C., the present accepted result being only 6,000° C.

He tried hot-air engines as well as steam engines for utilising solar energy, and claimed that the steam engine which he constructed in New York for this purpose in 1870 was the first one driven by the direct agency of solar radiation. The diameter of its cylinder was 4½ ins. He afterwards modified his solar hot-air engine so that it might be used as a small pumping engine using gas as its heat supply. "The profits upon this chip from his workshop are already estimated at several times the amount of the £20,000 expended by Ericsson upon the solar investigations leading up to this invention" (Vol. II. p. 275 of his "Life," by W. C. Church). Mouchot claimed, apparently correctly, that his engine was the first, and Ericsson admits that, "Some time previous to 1870, Mouchot made a small model engine, a mere toy, actuated by steam generated on the plan of accumulation by glass bells . . ."

Ericsson gives full details of all his apparatus for determining the solar constant in the record of his life's work, entitled, "Contributions to the Centennial Exhibition," New York, 1876; but unfortunately he did not describe in detail therein the solar boilers, explaining that, "Experienced professional men will appreciate the motive, viz., that of preventing enterprising persons from procuring patents for modifications." He does, however, give us the following amount of information: "On grounds already fully explained, minute plans of my new system of rendering sun-power available for mechanical purposes will not be presented in this work. The occasion, however, demands that I should present an outline of the concentration apparatus before referred to. It consists of a series of polished parabolic troughs, in combination with a system of metallic tubes charged with water under pressure, exposed to the influence of converging solar rays, the augmented molecular action produced by the concentration being transferred to a central receiver, from which the accumulated energy is communicated to a single motor.

"Thus the mechanical power developed by concentrated solar heat is imparted to the solar steam engine without the intervention of a multitude of boilers, glass bells, gauges, feeders, etc. Moreover, the concentration apparatus, unlike the instrument of Mouchot, requires no parallactic motion, nor does its management call for any knowledge of the sun's declination from day to day. Its position is regulated by simply turning a handle, until a certain index coincides with a certain bright line produced by the reflection of the sun's rays."

His boilers seem to have been exceedingly efficient, for he claims that "the mechanism which I have adopted for concentrating the sun's radiant heat abstracts, on an average, during nine hours a day, for all latitudes between the equator and 45°, fully 3·5 units of heat per minute for each square foot of area presented perpendicularly to the sun's rays." 3·5 B.T.U. sq. ft. min. = 0·95 calories sq. cm. min. The mean transmission of solar radiation by the atmosphere over a zenith distance from 45° E. to 45° W. is 67·5 per cent. when the sky is clear. Thus $0·675 \times 1·93 = 1·31$ calories sq. cm. min. are available at the earth's surface. Hence the efficiency of Ericsson's boiler was $\frac{0·95}{1·31} \times 100 = 72·5$ per cent., which is remarkably high.

In 1872 Ericsson built his hot-air solar engine, which had a reflector the shape of which was approximately a portion of a sphere, and which concentrated the solar radiation on to one end of the cylinder. The power of both these engines was evidently very small. On July 9th, 1875, Ericsson wrote that he had up to that time constructed and started seven sun motors.

Ericsson wrote in *Nature* of January 3rd, 1884, an illustrated article describing another of his sun motors which he erected in New York in 1883, in spite of his opinion as to the cost of solar steam (previously quoted) expressed in 1878. His description was as follows: "The leading feature of the sun motor is that of concentrating the radiant heat by means of a rectangular trough having a curved bottom lined on the inside with polished plates so arranged that they reflect the sun's rays towards a cylindrical heater placed longitudinally above the trough. This heater, it is scarcely necessary to state, contains the acting medium, steam or air, employed to transfer the solar energy to the motor; the transfer being effected by means of cylinders provided with pistons and valves resembling those of motive engines of the ordinary type. Practical engineers, as well as scientists, have demonstrated that solar energy cannot be rendered available for producing motive power, in consequence of the feebleness of solar radiation. The great cost of large reflectors and the difficulty of producing accurate curvature on a large scale, besides the great amount of labour called for in preventing the

polished surface from becoming tarnished, are objections which have been supposed to render direct solar energy practically useless for producing mechanical power.

"The device under consideration overcomes the stated objections by very simple means, as will be seen by the following description: The bottom of the rectangular trough consists of straight wooden staves, supported by iron ribs of parabolic curvature secured to the sides of the trough. On these staves the reflecting plates, consisting of flat window-glass silvered on in diameter, 11 ft. long, exposing 130 × 9·8 = 1,274 superficial inches to the action of the reflected solar rays. The reflecting plates, each 3 ins. wide and 26 ins. long, intercept a sunbeam of 130 × 180 = 23,400 square inches section. The trough is supported by a central pivot, round which it revolves. The change of inclination is effected by means of a horizontal axle—concealed by the trough—the entire mass being so accurately balanced that a pull of 5 lb. applied at the extremity enables a person to change the inclination or cause the whole to

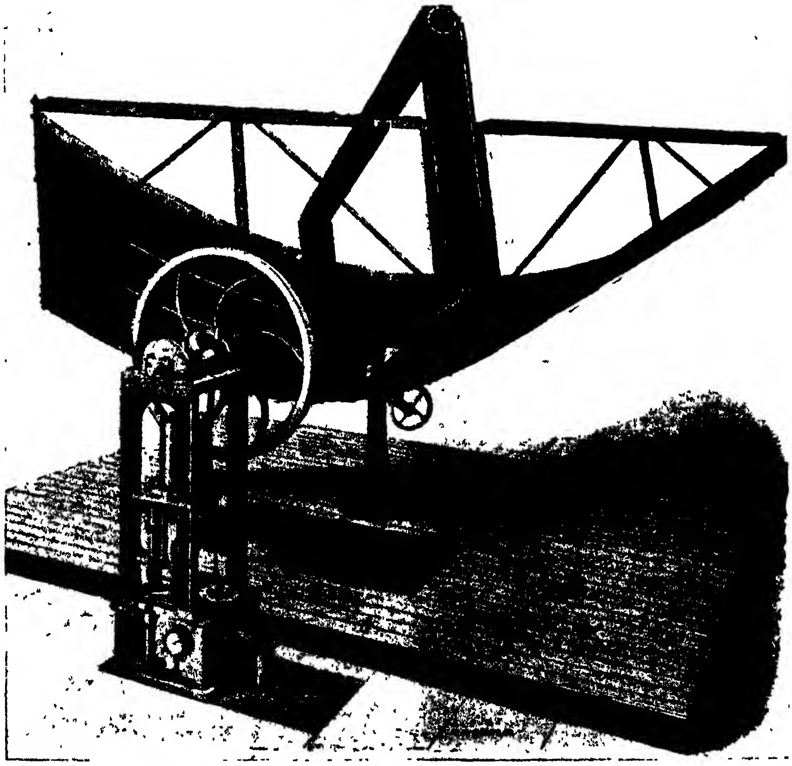

Fig. 3.—Ericsson's Sun-power Plant of 1883.

the underside, are fastened. It will be readily understood that the method thus adopted for concentrating the radiant heat does not call for a structure of great accuracy, provided the wooden staves are secured to the iron ribs in such a position that the silvered plates attached to the same reflect the solar rays towards the heater.

"Referring to the illustration, it will be seen that the trough, 11 ft. long and 16 ft. broad, including a parallel opening in the bottom, 12 ins. wide, is sustained by a light truss attached to each end, the heater being supported by vertical plates secured to the truss. The heater is 6¼ ins. revolve. A single revolution of the motive engine develops more power than needed to turn the trough, and regulates its inclination so as to face the sun during a day's operation.

"The motor shown by the illustration is a steam engine, the working cylinder being 6 ins. in diameter, with 8 ins. stroke. The piston-rod, passing through the bottom of the cylinder, operates a force-pump of 5 ins. diameter. By means of an ordinary cross-head secured to the piston-rod below the steam cylinder, and by ordinary connecting-rods, motion is imparted to a crank-shaft and fly wheel, applied at the top of the engine frame; the object of this arrangement

being that of showing the capability of the engine to work either pumps or mills. It should be noticed that the flexible steam-pipe employed to convey the steam to the engine, as well as to the steam-chamber attached to the upper end of the heater, have been excluded in the illustration. The average speed of the engine during the trials last summer was 120 turns per minute, the absolute pressure on the working piston being 35 lb. per square inch. The steam was worked expansively in the ratio of 1 to 3, with a nearly perfect vacuum kept up in the condenser enclosed in the pedestal which supports the engine frame.

"In view of the foregoing, experts need not be told that the sun motor can be carried out on a sufficient scale to benefit very materially the sun-burnt regions of our planet."

From the particulars given it is easily calculated that the "concentration" of this absorber was 9.

The Rev. C. H. Pope has produced a useful little book entitled "Solar Heat," the second edition of which was published in 1906. In it he tells us he started his experiments (which do not appear to have included the conversion of solar radiation into mechanical energy) in 1875. He used a modification of Mouchot's truncated cone reflector formed of many plane mirrors—the plan adopted about the same time by Adams. Pope has fallen into the same error *re* the connection between temperature and concentration of radiation as did Adams, for he says (p. 17): "That the degree and amount of heat at the focus will be proportionate to the area of the opening of the lens or mirror, and that thus the only limit to the temperature which may be reached is the size to which such lenses and mirrors may be constructed and revolved," and (p. 93): "These rays may, therefore, be gathered together and made to unite, as if they became one denser, stronger, hotter ray, so that the temperature of the condensed rays will be raised in proportion to the number of rays blended, and we can thus cause the heat to increase to any degree our apparatus can be enlarged."

W. Adams, Deputy Registrar, High Court, Bombay, seems to be the sole Englishman who has worked on the practical side of the problem of the utilisation of solar energy. His work was done in India, and is recorded in his interesting book "Solar Heat" (Bombay, 1878). He started on the work in 1876, and his experiments led him to conclude, as did Buffon, that silvered glass mirrors were superior to polished metal ones. This is no doubt true for ordinary use, though for laboratory experiments the polished metal ones give better results, as there is then no absorption by the glass.

In two particulars Adams was much at fault: (1) in believing that the solar rays which reach the earth are not practically parallel, and this in spite of the opposite opinions of the many physicists whom he quotes, and (2) in believing that the temperature attained at the focus of a lens or mirror is directly proportional to the concentration of the rays. As a consequence, he stated that if a lens 85 ft. 4 ins. in diameter concentrated the radiation on to a circle ½ in. in diameter the temperature would be 73,400,320° F. This is equal to 40,780,000° C., while the temperature of the sun itself is only 6,000° C., and no amount of such concentration could produce a temperature in excess of this. This error on the part of Adams and Pope seems to be due to a confusion of "temperature" with "quantity of heat."

His experiments were all made with plane or flat glass mirrors, the use of which he strongly advocated in preference to curved metal ones which Mouchot used. Sometimes he used groups of eighteen mirrors each 17 × 10½ ins., and sometimes of thirty-two, each 9 × 6 ins. The latter he arranged in a concave wooden frame in four tiers of eight in each tier. Such a group of thirty-two formed one unit, of which he had sixteen, all focused on to one boiler. When placed together, the sixteen units formed a portion of the surface of a hollow sphere 40 ft. in diameter. One of his boilers was of copper $\frac{1}{16}$ in. thick, 16 ins. diameter, 2 ft. 7 ins. high, and held 9 gallons of water which boiled in 30 mins. and evaporated 3¾ gallons in an hour.

His next boiler was also of copper ¼ in. thick, and of the same design and external dimensions as Mouchot's, but with a water space between the inner and outer shells of 3 ins., instead of 3 cm., and containing 12 gallons of water as compared with Mouchot's 4½ gallons. The 12 gallons of water were boiled and the pressure raised to 10 lb. sq. in. in the half hour from 7.30 a.m. to 8 a.m., and by 8.30 a.m. the pressure was 70 lb. sq. in. when the safety valve opened, whereupon he goes on to say: "A gentleman present kept the valve down by placing his foot on it, till the steam, escaping from several leaks in the joints of the fittings, made the position untenable. The weight on the safety valve was then supplemented by a brick suspended from the lever by a piece of string,

when suddenly the packing and red lead at the top of the dome under the socket of the steam-pipe (which had been fixed by my butler, who professed to have formerly been a fitter) gave way, and, with a terrific noise, the whole volume of steam rushed out of the opening. On turning off the solar rays and examining the boiler it was found to be dry. All the water had either been evaporated or blown out.

"When this boiler had been properly fitted up by professional fitters, a steam pump was hired, said to be of 2½ h.p., and it was connected with the steam-pipe. At 7.30 a.m. fire was opened on the boiler from the whole battery of sixteen mirrors, at a range of 20 ft., the boiler containing 12 gallons. At 7.45, *i.e.*, a quarter of an hour, there was a pressure of about 2 lb., and at 8.30 a.m. 55 lb. The steam was then turned into the cylinder of the pump, and the pump was kept working at a uniform pressure of about 30 lb. to the square inch.

"This pump, the first steam engine ever worked in India by solar heat, was kept going daily, for a fortnight, in the compound of my bungalow at Middle Colaba, in Bombay, and the public was invited, by a notification in the daily papers, to witness the experiments."

Adams also made a solar cooker, the reflector of which was formed of eight sheets of plane glass arranged so as to form a hollow truncated octagonal pyramid, 2 ft. 4 ins. in diameter at the larger end. The food was placed in a cylindrical copper vessel, at the axis, covered with an octagonal glass shade. With this he and others cooked many meals, both stews and roasts, and he records that both he and Mouchot found (p. 98) that animal fat "when exposed to the direct or reflected rays of the sun was converted into butyric acid, a substance having such an offensive odour and taste as to render the roast unpalatable. Mouchot then discovered that a sheet of red, pink, or yellow transparent glass, interposed between the roast and the reflector had the effect of preventing this fermentation, as those colours have the curious property of absorbing, neutralising, or eliminating the rays by which it is caused."

Adams also states (p. 36) that, "When the sacred fire that burned in the Temple of Vesta* became extinct, the ancient Romans used to rekindle it by placing a piece of dry wood in the linear focus of the conical reflector . . . To bring fire from heaven, by supernatural aid and a metal reflector was, no doubt, one of the most ancient miracles of priestcraft."

* Vesta, the Goddess of the Hearth.

He suggested many uses for solar heat, among others (p. 96), "for the cremation of deceased Hindus and others."

Taking into account the facts that he did not expend much money on his experiments, and that he did the whole of his solar work in eighteen months, it will be admitted his was a most creditable piece of work, especially as he was neither an engineer nor a physicist. To make this amply clear, he says: "I have neither the capital, the time, nor the practical knowledge required to conduct any business in which steam machinery is used. I know now that the 'governors' of a steam engine are the two iron globes which revolve about it, and not, as I had supposed, the two men who lubricate the machine and feed the boiler with coals. That is

FIG. 4.—ADAMS'S SOLAR COOKER, 1876.

nearly the extent of my knowledge of steam machinery."

In concluding this brief account of Adams's work, you will be pleased to learn that he was awarded the gold medal of the Sassoon Institute of Bombay for his essay on "The Utilisation of Solar Heat," which he submitted in March, 1878.

In *Comptes Rendus*, Vol. XCI. 1880, pp. 388–9, Mons. Abel Pifre claims an efficiency of 80 per cent. for his apparatus when, he says, he obtained a rate of absorption of 1·21 calories sq. cm. min. If such a rate were obtained, we now know it would mean an efficiency of 89·7 per cent., which is improbable. Pifre used a parabolic reflector (instead of a truncated cone), and reduced the surface of the boiler, thus increasing the concentration. The capacity of his boiler was 11 gallons, and he collected 100 sq. ft. of solar radiation, so the diameter of his reflector was about 11 ft. 4 ins. He used a rotary pump, and raised 99 litres of water 3 metres in

14 minutes, which is equivalent to 0·065 h.p. He ran a printing press with his sun-power plant, and claimed that if he had collected 216 sq. ft. of radiation he could have produced 1 h.p., which is quite likely.

Next in order we have Langley's work, which consisted of many experiments to determine the value of the solar constant, the value of which he gave as 3·0 calories sq. cm. min.

Langley experimented with de Saussure's "hot box," and was the leader of the expedition to Mount Whitney, where some of his best work was done. He gave a preliminary account of this trip in *Nature* of August 3rd, 1882, pp. 314–17, and a full record of it under the title "Researches on Solar Heat" in the U.S.A. War Dept., Papers of the Signal Service, XV., 1884. He also referred to it in "The New Astronomy" (1900).

In *Nature* (p. 315) he said: "As we still slowly ascended, and the surface temperature of the soil fell to the freezing-point, the solar radiation became intenser, and many of the party presented an appearance as of severe burns from an actual fire, while near the summit the temperature in a copper vessel, over which were laid two sheets of plain window glass, rose above the boiling-point, and it was certain that we could boil water by the direct solar rays in such a vessel among snowfields."

In Vol. LXXIII. of the *Proceedings*, Inst. C.E., 1883, p. 284, is described a plant designed by J. Harding, M.Inst.C.E., for distilling water by solar radiation.

This plant was erected at Salinas, Chile, 4,300 ft. above sea-level, and had 51,200 sq. ft. of glass arranged in sections 4 ft. wide, and in the form of a very flat Λ, forming the roof of a shallow water trough. The sun evaporated the water, and the resulting vapour condensed on the glass, for the temperature in the box was far higher than that of the atmosphere, and hence of the glass. The pure water trickled down the sloping glass and dripped from its lower edge into a small channel on the top of each side of the box. These channels delivered into larger ones, and thus the distilled water was collected. The plant yielded 5,000 gallons of pure water per day in summer, *i.e.*, 1 lb. of water per square foot of glass. Allowing for interest on capital, cost of repairs, etc., the cost of the pure water is said to have been less than ¼*d.* per gallon. The chief item of expense was the breakage of glass by whirlwinds. Distillation started at 10 a.m. and continued to 10 p.m. The maximum temperature of the water in the troughs was 150° F. The total cost of the plant, including pumps, windmills and tanks, was $50,000, or 1*s.* 6*d.* per square foot of glass.

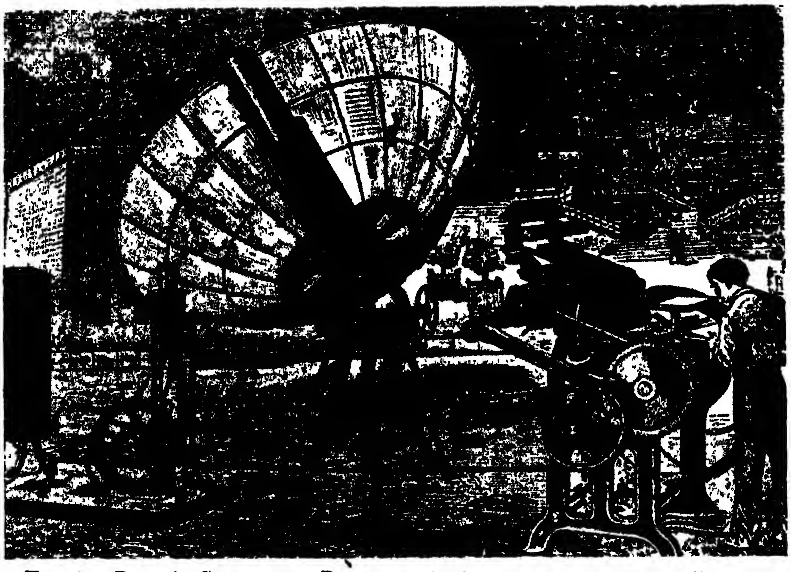

Fig. 5.—Pifre's Sun-power Plant of 1878 driving a Printing Press.

It is not clear when the solar energy problem first engaged the attention of C. L. A. Tellier, a French refrigerating engineer; but in 1889 he published his book, "Élévation des Eaux par la Chaleur Atmosphérique," in which he gave many drawings and details, and a very full description of his plant. He may have been the first to use the lamellar boiler, but the

U.S. Patent No. 230,323, of July 20th, 1880, of MM. Molera and Cebrian, shows that they proposed this form of boiler. The dimensions of each section of Tellier's boiler were 3·50 m. × 1·12 m. They were made of thin plates of iron, so riveted together as to give them a quilted formation. They were filled with ammonium hydrate, which, he says, when heated by the sun produced gaseous ammonia at a pressure of "several atmospheres." The ammonia gas was used in a small vertical engine, and was then liquified in a condenser and used again. The boilers were fixed in a sloping position so as to "face the sun," and two somewhat fanciful illustrations show them used as roofs of verandahs. The boilers were insulated on their lower or shade sides to prevent loss of heat, and were placed in shallow boxes with only one layer of glass to form the cover. He experimented with different coloured glass, and found, as might be expected, that colourless glass gave the best results. He also gave complete details of his invention as applied to the manufacture of ice. With so much detail it is disappointing that the author could not find the results of a single experiment with the plant. In fact, he is not sure whether Tellier ever constructed one.

In his work "La Conquête Pacifique de l'Afrique Occidentale" (1890), Tellier discussed social and economical questions, and showed how improvements might be made by rendering the deserts of Africa productive by means of his sun-power plants.

A. G. Eneas, in the United States, used the popular truncated cone-shaped reflector, collecting about 700 sq. ft. of solar radiation. The weight of the reflector was 8,300 lb.

The boiler was formed of two concentric steel tubes, the two together being encased in two glass tubes with an air space between them, and another air space between the inner glass one and the outer steel tube. The water circulated up between the inner and outer steel tubes and down the inner tube. The boiler was placed at the axis of the cone. Its length was 13 ft. 6 ins., its water capacity 834 lb. (13·4 cubic ft.), and steam space 8 cubic ft. Hence the diameter of the outer tube appears to have been 1 ft. 2 ins., and the concentration of radiation 13·4, *i.e.*, 13·4 sq. ft. of sunshine were concentrated on each square foot of the external surface of the boiler.

C. G. Abbot ("The Sun," p. 369) states that Eneas gave him the following particulars :—

"February 14th, 1901.—Pasadena, California, 11.30 a.m.—0.30 p.m. 642 sq. ft. sunshine. Temperature of air, 61° F. Steam pressure, 145–151 lbs. sq. in. Steam condensed, 123 lb.

"October 3rd, 1903.—Mesa, Arizona, 'About midday.' 700 sq. ft. sunshine. Temperature of air, 74° F. Average steam pressure, 141 lb. per sq. in. Steam condensed, 133 lb.

"October 9th, 1904. — Willcox, Arizona, 11.0—12.0. 700 sq. ft. sunshine. Steam pressure, 148–156 lb. sq. in. Steam condensed, 144·5 lb."

The temperature of the feed-water is not given, but assuming it to be the same as the temperature of the air, we can deduce the rate of absorption per square foot of radiation, and the thermal efficiency of the absorber. This being done we obtain the following table :—

Place and Date.	Period.	Weight of Steam produced in lb.	Mean pressure of steam in lb. sq. in. abs.	Rate of absorption per square foot of radiation collected. B.T.U. per hour.	Thermal Efficiency of the Absorber. Per cent.*
Pasadena, Feb. 14th, 1901.	11.30 a.m. to 0.30 p.m.	123	163	223	74·6
Oct. 3rd, 1903.	"About midday"	133	156	219	73·3
Willcox, Oct. 9th, 1904.	11.0 a.m. to 12.0 noon	144·5	167	238	79·6

* For a maximum transmission of radiation through the atmosphere of 70 per cent.

Eneas refers to his "nine different types of large reflectors," and found that he obtained better results when he concentrated the reflected rays "on two parts of the boiler instead of its entire length, as in the Pasadena machine." The unexposed portions of the boiler then appear to have been lagged.

Eneas said, "I find 3·71 B.T.U. per sq. ft. per min. as the greatest amount of heat obtainable during the trial runs." This gives a maximum efficiency of 74·5 per cent., which agrees

with the result given for his Pasadena plant in the foregoing table.

Eneas also stated that, "the interposition of a single thin glass plate in a beam of sunlight diminishes the intensity about 15 per cent. This decrease is owing principally to reflection." On p. 466 of Preston's "Treatise on Heat," it is stated that, "Mirror glass 2·6 mm. thick transmitted 39 per cent. of the radiation that fell on it from a Locatelli lamp, while rock-salt transmitted 92 per cent." The diathermancy of each substance varies with the nature of the source of heat, so the result just given is not comparable with that given by Eneas.

Abbot found the following percentages of heat were transmitted through sheets of glass, each from 1·5 to 2 mm. thick. In one set of experiments the glass was normal to the rays, and the other at 45°.

Number of Sheets of Glass.	Percentage transmission.	
	Rays normal to glass.	Rays at 45° to glass.
1	86·5	85·0
2	74·5	71·8
3	63·5	60·0
4	53·3	49·0

FIG. 6.—THE PASADENA SUN-HEAT ABSORBER OF 1901.

The sun-power plant known as the Pasadena* one was described and illustrated in the August, 1901, issue of *Cassier's Magazine* by Professor R. H. Thurston, LL.D., D.E., and on p. 103 of *The Railway and Engineering Review* of February 23rd, 1901. It is stated to have

* There appear to have been several plants erected at Pasadena by different experimenters. Probably Eneas designed the plant above described.

been designed by, and erected at the expense of, "a party of Boston inventors whose names have not been made public." It consisted of a truncated cone reflector, 33 ft. 6 ins. in diameter at the larger end and 15 ft. diameter at the smaller, with a boiler 13 ft. 6 ins. long, having a capacity of 100 gallons (U.S.A.) plus 8 cubic ft. of steam space.

The article in *The Railway and Engineering Review* states: "According to newspaper accounts, the all day average work performed by the engine is 1,400 gallons (U.S.A.) of water lifted 12 ft. per minute, which is at the rate of 4 h.p." It is more nearly 4¼ h.p., thus this plant required 150 sq. ft. of radiation per horse-power, and the concentration appears to have been 13·4.

The Pasadena plant is said to have cost £1,000, and Willsie, writing of it in 1909, says it was "the largest and strongest of the mirror type of solar motor ever built."

H. E. Willsie and John Boyle, Jun., started their work in America in 1902. The method they adopted was to let the solar radiation pass through glass and heat water, which in turn was used to vaporise some volatile fluid such as ammonium hydrate, ether, or sulphur dioxide, the vapour being used to drive an engine.

Willsie thinks he was the first to propose this two-fluid method for the utilisation of solar energy, and so far as the author knows his claim is correct. Their first sun-heat absorber was built at Olney, Illinois, U.S.A., and consisted of "a shallow wooden tank tightly covered with a double layer of window glass. The sides and bottom were insulated by enclosed air spaces filled with hay. The tank was lined with tar paper, well pitched to hold water to the depth of 3 ins. Although the weather was cold and raw, even for October with occasional clouds, the thermometer in the water showed temperatures higher than were needed to operate a sulphur dioxide engine.

"The next solar heater was built at Hardyville, Arizona. Sand was used for insulation. Three tests for the amount of heat gave these average results in December:—

Test No.	Heat units absorbed per sq. ft. per hour.
1	120
2	122
3	148

"An estimate showed that 50 per cent. of the heat reaching the glass was absorbed into the water.

"In 1903 some further heater tests were made, patent applications filed, and to carry on experiments on a more extensive scale the Willsie Sun Power Company was incorporated.

"In the spring of 1904 a complete sun-power plant was built at St. Louis. In this installation a 6 h.p. engine was operated by ammonia. The heater consisted of a shallow wooden basin coated with asphalt and divided by strips into troughs. It was covered by two layers of window-glass and insulated at the sides and bottom by double air spaces. Each trough of the heater formed a compartment. The troughs were inclined so that a thin layer of water flowed from one trough to the next. In this heater was collected and absorbed into the water from the sun's rays 211,500 heat units per hour at noon, or 377 heat units per hour per square foot of glass exposed to the sun. As, according to accepted solar observations, about 440* heat units per hour reached a square foot of glass, this heater was showing the surprising efficiency of 85 per cent., and collecting nearly twice as much solar heat per square foot per hour as did the apparatus of Ericsson. Of the lost heat I estimated that 40 heat units were reflected and absorbed by the glass and that 23 heat units were radiated. On cloudy days the water could be heated by burning fuel. A description of this plant appeared in a St. Louis paper and in a New York paper, but so far as I know it has not been mentioned in any technical publication.

"It was then decided to build a sun-power plant on the desert, and some land about a mile from the Needles, Cal., was purchased for a site."

This Needles plant used sulphur dioxide, and its results decided them to build a larger plant, which Willsie speaks of as their third sun-power plant, and describes as follows: "A 20 h.p. slide-valve engine was connected to an open-air water-drip condenser and to a fire-tube boiler 22 ins. × 19 ft. having fifty-two 1-in. tubes. The solar-heated liquid flowed through the tubes giving up its heat to the sulphur dioxide within the boiler. Boiler pressures of over 200 lb. were easily obtained. The engine operated a centrifugal pump, lifting water from a well 43 ft. deep (*sic*), and also a compressor, in addition to two circulating pumps."

Their fourth plant was a rebuilding of the third, and they tried the expedient of covering the heat-absorbing water with a layer of oil, but the results were not so good as when a heat-absorbing liquid (water, or oil, or a solution

* No, only 299. Note.—0·70 × 1·93 = 1·352 calories sq. cm. min. = 299 B.T.U. square foot hour.

of chloride of calcium) was rapidly circulated in a thin layer. The sun-heat absorber for this plant was in two sections, one covered with one layer of glass and one with two layers, and both on a slope, the liquid running from the first to the second, and its temperature in the two sections being 150° F. and 180° F. respectively. The liquid at 180° F. was distributed over a "heat exchanger" consisting of horizontal pipes about 3 ins. in diameter arranged in a vertical plane, something like an air condenser. The pipes contained sulphur dioxide, and the heat-absorbing liquid lost about 100° F. in its descent. The cooled liquid was returned to the two sections of the absorber to be reheated. The heat exchanger was enclosed in a glass-covered shed. Willsie says: "The engine used in this experiment was a vertical automatic cut-off, which at times, with a boiler pressure of 215 lb., probably developed 15 h.p. The two-heater sections exposed an area of about 1,000 sq. ft. to the sun, but as the heat was taken from storage and not directly from the heater, it is not fair to assume the above proportion of heater surface to horse-power developed.

"The condenser consisted of six stacks of horizontal pipes, twelve pipes to the stack. The cooling water, pumped from a well 43 ft. deep, had a temperature of 75° F. Only enough water was allowed to drip over the pipes to keep them wet, and so great was the evaporation in the dry desert breeze that the cooling water left the lower pipes at 64°. By using the cooling water over and over, the condenser gave very satisfactory results. A shade of arrowweed, a straight willow-like shrub abundant along the Colorado River, kept the sunshine from the condenser pipes and permitted a good air circulation."

Willsie estimated the cost of his sun-power plant, complete with engine, at £33 12*s*. per h.p.

With regard to Willsie's results, it is to be noted that 377 B.T.U. per hour means an efficiency of $\frac{377 \times 100}{60 \times 0{\cdot}70 \times 7{\cdot}12} = 126$ per cent.; for we now know that a maximum of only about 299 B.T.U. per square foot per hour penetrate the atmosphere. The author agrees with the 50 per cent. efficiency given a little earlier by Willsie.

Frank Shuman, of America, started on the problem in 1906, and in 1907 he had a plant running which developed about 3½ h.p.; 1200 sq. ft. of sunshine fell on to a fixed, horizontal water-box with a glass top. In the water there were rows of parallel horizontal black pipes containing ether, and exposing 900 sq. ft. of surface to the solar radiation. The water also became heated and conveyed heat to the under sides of the pipes. The ether boiled, and its "steam" drove a small vertical, simple, single-cylinder engine. The exhaust ether vapour passed into an air surface condenser, and the liquid ether from this was pumped back into the tubes of the "boiler" already described.

This plant, Shuman says, ran well even when snow was lying on the ground. This at first seems very remarkable, but though in the winter the number of solar rays falling on a given horizontal area is smaller than in summer, the permeability of the atmosphere is about 20 per cent. greater in winter than in summer, which counteracts the other effect: but of course the loss of heat by conduction from the boiler is greater in winter than in summer.

In 1910 Shuman constructed an experimental unit of an absorber measuring 6 ft. × 9 ft. This unit combined the lamellar boiler of Tellier and the hot box of de Saussure, for it consisted of a shallow black box with double glass top with 1 in. of air space between the two layers of glass, another air space of an inch between the lower glass and the boiler, which was 6 ft. long (up the slant), 2 ft. 6 ins. wide, and ¼ in. thick over all. The box was so sloped that at noon the rays of the sun were perpendicular to the glass. The box was not moved to follow the sun, but it was adjusted about every three weeks, so that the condition just named was complied with. The remarkable thing about the absorber was that there was no concentration of any kind of the sunshine by mirrors, lenses or other means, and yet the author on one occasion recorded a temperature of 250° F. in the box. The best run of an hour's duration produced steam at atmospheric pressure at the rate of 7½ lb. per 100 sq. ft. of sunshine falling on the box. The author's tests of a Shuman 100 h.p. low-pressure engine at Erith showed the steam consumption to be 22 lb. at atmospheric pressure per brake horse-power hour. Hence, with an absorber of the type just described, it would be necessary to collect solar radiation to the extent of 300 sq. ft. per brake horse-power, which is a much larger area than any named by other workers. The maximum thermal efficiency of this absorber was 24·1 per cent.

In 1911, with the aid of some English capitalists, Shuman constructed his third absorber at Tacony (a suburb of Philadelphia), which was almost identical with the one just described, except that it had two plane mirrors,

FIG. 7.—GENERAL VIEW FROM THE WEST OF THE SHUMAN ABSORBER, TACONY, 1911.

one at the upper edge of the hot box and one at the lower, so arranged that 6 sq. ft. of sunshine were concentrated on to 3 sq. ft. of hot box, *i.e.*, the concentration was 2 to 1. Its position was adjusted about every three weeks. This time the total quantity of solar radiation collected as many times as large as the largest collected by any previous worker, for the total area was 10,296 sq. ft. In the best run of one hour this plant produced 816 lb. of steam at atmospheric pressure. This is at the rate of 9 lb. per 100 sq. ft. of sunshine, and therefore equivalent to an allowance of 245 sq. ft. of sunshine per brake horse-power. The maximum thermal efficiency of this absorber was 29·5 per cent.

Towards the end of 1911 the Sun Power Company (Eastern Hemisphere), Limited, requested their consulting engineers (Messrs. A. S. E. Ackermann and C. T. Walrond) to select and invite some distinguished physicist to join them in a consultative capacity. Hence Professor C. V. Boys, F.R.S., became associated with the work, and he suggested a vital change in the design of the absorber, viz., that the boilers should be placed on edge in a channel-shaped reflector of parabolic cross-section, so that solar radiation was received on both their surfaces, instead of one being worse than idle, as it was when the boilers were placed "side on" to the sun. The design immediately received the hearty approval of the consulting engineers and

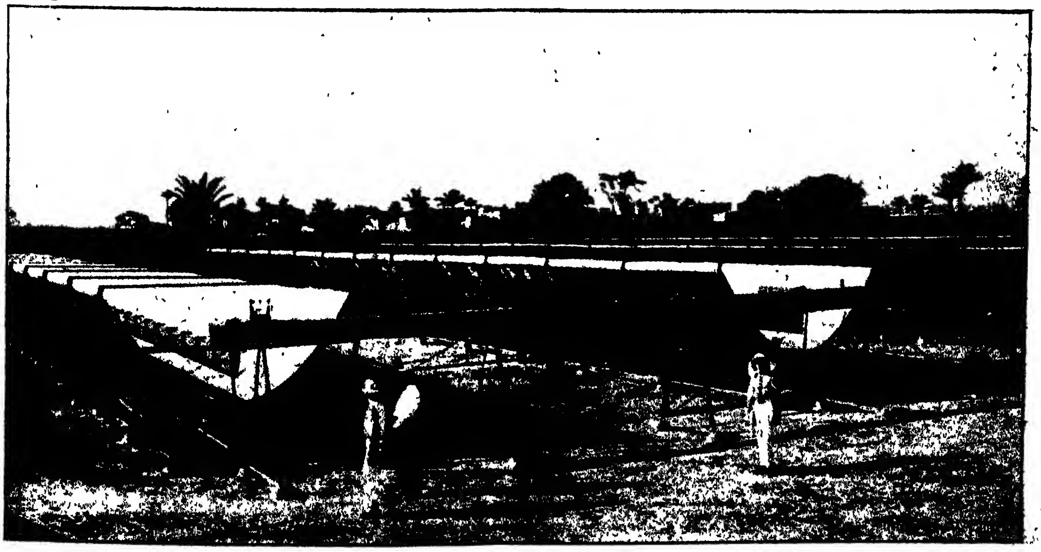

FIG. 8.—GENERAL VIEW FROM THE SOUTH OF THE SHUMAN-BOYS ABSORBER, MEADI, 1913.

Shuman, and at the time we all thought the arrangement was novel, but the author has since found and recorded herein that Ericsson used a very similar reflector and boiler.

An absorber of this design was constructed and erected at Meadi on the Nile, seven miles south of Cairo, in 1912, but the boiler was constructed of thin zinc and failed before the official tests could be made. This boiler was replaced by a cast-iron one in 1913, and the author (accompanied by his old pupil, G. W. Hilditch, A.M.Inst.C.E., as his chief assistant, now Lieut. Hilditch of the Divisional Engineers, Royal Naval Division) spent two most interesting months with the plant in July and August, 1913. He went out in time to tune up the Shuman engine (a 100 h.p. one) taken out from Tacony, and make all the necessary preparations for the trials, of which there were over thirty-five.

In addition to the alteration of the shape of the reflectors, another very important change was made. Their axes were placed north and south, and they were automatically heeled over from an eastern aspect in the morning to a western one in the evening so as to "follow the sun." Thus the same number of solar rays were caught all day long, and the small decrease in steam production in the morning and evening was almost entirely due to the greater thickness of atmosphere through which the rays had to pass. The total area of sunshine collected was 13,269 sq. ft.

The boilers were placed at the focus of the reflectors and were covered with a single layer of glass enclosing an air space around the boilers. Each channel-shaped reflector and its boiler was 205 ft. long, and there were five such sections placed side by side. The concentration was 4½ to 1. The maximum quantity of steam produced was 12 lb. per 100 sq. ft. of sunshine, equivalent to 183 sq. ft. per brake horse-power, and the maximum thermal efficiency was 40·1 per cent. The best hour's run gave 1,442 lb. of steam at atmospheric pressure, hence (allowing the 22 lb. of steam per brake horse-power hour) the maximum output for an hour was 55·5 b.h.p., a result about ten times as large as anything previously attained and = 63 b.h.p. per acre of land occupied by the plant. A pleasing result was that the output did not fall off much in the morning and evening. Thus on August 22nd, 1913, the average power for the five hours' run was no less than 59·4 b.h.p. per acre, while the maximum and minimum power on that day were 63 and 52·4 b.h.p. per acre respectively.

The work of MM. G. Millochau and Ch. Féry was started in 1906 to determine the solar constant and the temperature of the sun. Their work is recorded in *Comptes Rendus* for 1906

FIG. 9.—SHUMAN-BOYS ABSORBER, MEADI, 1913. ONE SECTION OF THE ABSORBER FROM THE NORTH.

and 1908, and in the *Revue Scientifique* of September 7th, 1907. They give the absolute temperature of the sun as 6,042° C., and the value of the solar constant as 2·38 calories sq. cm. min. This latter value was the result of experiments they made on the summit of Mont Blanc in 1908.

The article in the *Revue Scientifique* of September 7th, 1907, is by Millochau, and in it he gives the following list of experimenters and the results of their determination of the solar constant, after reading which some may consider the word *constant* a misnomer:—

Pouillet	1837	1·793
Forbes	1842	2·82
O'Hagen	1863	1·9
Voille	1875	2·28 to 2·37
Langley	1884	3·068
Savelief	1889	3·47
Pertner	1889	3·05 to 3·28
Angerström	1890	4·00
Hansky	1905	3·29

To these we may add:—

Herschel	1837	1·98
Ericsson	1876	1·93
Millochau and Féry	1907	2·38
Abbot	1913	1·93

In spite of this history of comparative failures, the author is of opinion that the problem of the utilisation of solar energy is well worthy of the attention of engineers, for even now it is very nearly a solved problem where there is plenty of sunshine and coal costs £3 10*s*. a ton. It is fortunate that where coal is dear sunshine is often plentiful, and it is to be remembered that coal will gradually get dearer while the cost of manufacture of sun-power plants should decrease. Sun-power plants are admirably suitable for pumping in connection with irrigation, for where there is most sunshine there is need for most irrigation, and the slight variation in the quantity of water pumped throughout the day does not matter. Also, when temporarily there is no sunshine (due to clouds), probably little or no irrigation is required.

In conclusion, the author would refer those who are interested in the subject to his paper (8vo, 86 pages, with 22 illustrations), bearing the same title as this one, presented to the Society of Engineers on April 6th, 1914. Therein he dealt fully with the whole of Shuman's work from 1910–13 inclusive, and gave details of the results of the sixty-two trials of the plant made by the author in England, the United States and Egypt.

APPENDIX I.

HEAT REJECTED.

In the case of the Shuman-Boys absorber, tested by the author at Meadi, Egypt, it seemed reasonable to suppose that when the boilers were naked—*i.e.*, when they were not covered with clear glass to prevent loss by heat by conduction—the quantity of solar heat not used would bear some relation to the difference between the temperature of the boiler and that of the atmosphere. On calculating the quantity of unused heat per hour in B.T.U. per square foot of boiler surface for the first ten trials, *i.e.*, all those in which the boilers were naked, we obtain the following results, and as the maximum variation is only from 5·5 below the mean to 5·1 above it, we may, perhaps, call the quantity a constant:—

Trial No.	Solar heat not used expressed in B.T.U. per hour per square foot of boiler surface per 1° F. difference in temperature between the boiler and the air.
1	8·20
2	8·85
3	9·12
4	8·99
5	8·73
6	8·85
	8·68
	8·56
	8·47
10	8·37
Mean	8·68

The quantity is not constant when the boilers are covered.

APPENDIX II.

THE THEORETICAL THERMAL EFFICIENCY OF A SOLAR HEAT ABSORBER.

The available solar heat per square foot of radiation is sa where s is the solar constant in B.T.U. per square foot per min. = 7·12, and a is the coefficient of atmospheric transmission which varies with the time of day. Under good conditions

the available solar heat (= 60 *sa* B.T.U. per hour) is as follows:—

Time of day. A.M.	Available heat in B.T.U. per normal square foot of solar radiation per hour.
7.0	225
8.0	260
9.0	276
10.0	288
11.0	295
noon	299
P.M.

2.0	288
3.0	276
4.0	260
5.0	225

The loss of heat in the case of an absorber consisting of a reflector and naked boiler is made up of several factors, including r, the loss due to the inefficiency of the reflector, and that due to R, the radiation and conduction of heat from the boiler.

Let D be the width in feet of the reflector.
" p " perimeter in feet of the boiler.
" r " efficiency of silvered glass as a reflector of heat.
" s " solar constant in B.T.U. per square foot per min. = 7·12.
" a " coefficient of atmospheric transmission.
" T " absolute temperature in degrees F. of the boiler.
" A " absolute temperature in degrees F. of the reflectors.

The temperature A was found to be about 9° F. above the shade temperature of the atmosphere. Then the solar heat arriving at the absorber (considering one foot run of absorber) is H = D*sa* B.T.U. per minute.

An expression to represent the loss of heat from the boilers is less easy to obtain. The author has assumed that Stefan's law of radiation applies provided the constant k in Stefan's equation is determined under conditions almost identical with those in which we wish to apply the law. Hence R, the net heat loss by radiation *and conduction* from the boiler $= pk\ (T^4 - \frac{2}{3} A^4)$ B.T.U. per square foot per minute. The term $\frac{2}{3} A^4$ occurs because, while the boilers are sending out radiant heat, they are receiving radiant heat from the mirrors by *reason of their temperature*, and quite apart from the heat which they *reflect* on to the boilers. The $\frac{2}{3}$ is because the boilers are encircled by the mirrors for only $\frac{2}{3}$ of the perimeter of the boilers. The heating of the mirrors is due to two causes: (1) the inefficiency of the mirrors as reflectors, and (2) the heat of the air and ground.

With regard to the value of k, it fortunately happened in 1899 that the author made some very complete tests of the warming plant then recently installed in the Nurses' Home of the Hospital for Sick Children, Great Ormond Street, London. The mean temperature of the radiators was 201° F., which is to be compared with temperatures ranging from 184° F. to 235° F. of the solar boilers in Egypt, while the mean temperature of the air surrounding the radiators in the Home was 81° F. This has been taken to be equal to the surface temperature of the walls of the Home (the temperature of the air on the other side of the walls was 69° F.), and is to be compared with temperatures ranging from 95° F. to 106° F., the temperatures of the mirrors in Egypt. In the Home the air was almost motionless, while in Egypt the speed of the wind varied from 3·4 to 10·4 miles per hour, which would cause a greater loss by conduction. In both cases the hot water was contained in cast-iron vessels about $\frac{3}{8}$ in. thick, but while in the case of the radiators at the Home the surface was plain unpainted cast iron, in Egypt the cast iron was painted with a mixture of lamp-black and turps, which, while absorbing heat more readily, also radiates it more quickly. These conditions lead us to expect that the Egyptian plant was less efficient than the calculated efficiency.

Putting in the Home trial values in Stefan's equation, $R = pk\ (T^4 - A^4)$ B.T.U. per square foot per minute, and making $p = 1$ foot, we find $k = 10^{-10} \times 0{\cdot}36$ B.T.U. per square foot per minute. (This value of k differs greatly from that determined by Kurlbaum for radiation only.)

Lastly, there is the loss of solar heat due to the inefficiency of the mirrors. This is given by $M = (1 - r)Dsa$ B.T.U. per square foot per minute. Hence the equation to the efficiency of the absorber is

$$\eta = \frac{H - R - M}{H} = \frac{Dsa - pk\ (T^4 - \frac{2}{3}A^4) - (1 - r)\ Dsa}{Dsa}$$

In working out an actual case, much depends on the values selected for a and r. As a single sheet of glass stops 15 per cent. of solar heat, and as the solar radiation has to pass *twice* through the glass of a mirror, as well as to sustain a loss at the surface of the silvering, and another by some penetration of the silvering, we shall probably not be far wrong in taking $r = 0{\cdot}6$. Doing this, and using the values of 60 *sa* tabulated above, and inserting the values of the other quantities found experimentally in Egypt ($D = 12{\cdot}67$ feet, $p = 2{\cdot}92$ feet), we obtain the results given in the table on page 559.

The efficiency has not been calculated for every trial, simply on account of time and labour already expended on this paper.

The ratio $\dfrac{\text{Calculated thermal efficiency}}{\text{Actual thermal efficiency}}$ is not as constant as one would like to see it, but it must be remembered that the experiments were on a very large scale, in the open, and with an unusual number of possible variables. If we exclude the results of the naked boiler trials when the wind speed was relatively high, the mean of the rest of the ratios is 1·10, showing that on the average the calculated efficiencies are 10 per cent. too high.

It will be noticed that though the equation to the theoretical efficiency was obtained on the

assumption that the boilers were naked, it has been applied to the cases in which the boilers were covered with one layer of glass, thus encasing them with warm air, which, while reducing the loss by conduction, deducts a further 15 per cent. on account of the penetration loss. The sheets of glass were simply placed edge to edge, side by side, with no jointing material, so the envelope was by no means air-tight.

Considering the results, it would appear as if the equation applied even better to covered than to naked boilers. The most divergent results are those for trials Nos. 6-10 inclusive, when the boilers were naked, and when the speed of the wind was about twice what it was during the other naked boiler trials. This is to be expected, as the wind greatly increases the loss of heat by conduction. When covered, the effect of wind is greatly reduced—compare trials Nos. 11-15 inclusive, when the wind was about 4½ miles per hour, with trials Nos. 16-20 inclusive, when the wind was 7 miles per hour.

In the author's previous paper* the actual thermal efficiencies given on the large table facing page 106 were (as the footnote there states) based on the only information he had at the time, but in the table just given they have been worked out with 1·93 calories per sq. cm. min. as the value of the solar constant, and with the coefficient of atmospheric transmission adjusted for the mean time of day of each trial. The result is that the efficiencies are much more nearly constant for each day's trials. On different days the humidity was not always the same, nor were the conditions of the boilers or mirrors.

APPENDIX III.

THEORETICAL COMMERCIAL OR OVERALL EFFICIENCY OF A SOLAR HEAT ABSORBER AND ENGINE.

It might readily be thought—in fact, it is probably a popular fallacy—that the best commercial result (or overall efficiency) obtained from a solar plant would be when the thermal efficiency of its absorber was a maximum, but this is not necessarily the case, as has been explained fully in the author's former paper (pp. 109 *et seq.*). Briefly it may be said that when a low temperature is maintained in the boiler, the difference in temperature between its outside and inside is great, and the exchange of heat is great, *i.e.*, the thermal efficiency is high. But low-temperature steam is of less value for power purposes than high-temperature steam. Thus a high commercial, or power-producing, efficiency of the plant is not necessarily associated with a high thermal efficiency of the absorber.

Hence the overall efficiency of a sun-power plant will be the product of the efficiency of the absorber into the efficiency of the engine using the steam. As different engines have different efficiencies, it is usual for engineers to compare results with a so-called "perfect," or Carnot, engine, the efficiency of which is $\frac{T - T_2}{T}$ where T is the absolute temperature of the steam, and T_2 is the absolute temperature of the condenser. T_2 has been taken as constant, and $= 568°$ F.

Hence the equation to the overall efficiency of the plant is

$$\eta_0 = \frac{\{ Dsa - pk\,(T^4 - \tfrac{2}{3}A^4) - (1-r)\,Dsa \}\,(T - 568)}{Dsa\ T}.$$

If we assume the mirrors to have a temperature of 100° F., then, by inserting the values of the other symbols (except T), we get

$$\eta_0 = 0{\cdot}71 - 1{\cdot}664 \times 10^{-12}\,T^4 - 404\,T^{-1} + 9{\cdot}45 \times 10^{-10}\,T^3.$$

Differentiating this equation with regard to T, and equating the result to 0, we obtain the value of T, which gives the maximum overall efficiency under the given conditions.

This being done, we find T = (231 + 461)° F., corresponding to a steam pressure of 21 lb. sq. in. abs. Inserting this value of T in the equation just given, we find the *theoretical* maximum overall efficiency of the Meadi absorber, combined with a

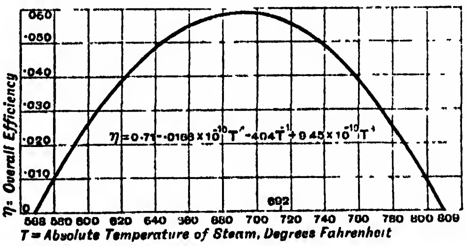

FIG. 10.—CURVE SHOWING THE RELATION OF THE OVERALL EFFICIENCY OF THE 1913 SHUMAN-BOYS SUN-HEAT ABSORBER (WITH NAKED BOILER), COMBINED WITH A CARNOT ENGINE, TO THE ABSOLUTE TEMPERATURE OF THE BOILER STEAM.

Carnot engine, is 5·9 per cent., while the *actual* maximum was 4·32 per cent. The relative efficiency was thus 73·2 per cent. This means that we obtained nearly ¾ of the b.h.p. theoretically possible under the stated conditions.

Instead of differentiating the equation to η, we may insert various values of T, and thus calculate the corresponding values of η_0 and plot the results. The temperature, which gives the maximum commercial economy, is then readily seen by inspection to be 231° F. as before. (*Vide* Fig. No. 10.) We also see that $\eta_0 = 0$ when T = 568° F. ($= T_2$, the temperature of the condenser), or when T = 809° F. The latter corresponds with a steam pressure of 131 lb. sq. in. abs., and means that the loss by radiation and conduction from the boilers and by the inefficiency of the mirrors would then be equal to the solar heat received.

DISCUSSION.

The Chairman (Charles Vernon Boys, F.R.S.), in opening the discussion, said all must be impressed by the wonderful perseverance and untiring energy of the author in preparing the paper. Anyone reading it and seeing the small proportion of the sun heat that was available—4·32 per cent.—would be disappointed that it should be so small. It was almost disheartening, but he (the Chairman) would ask the audience to consider what the position was with regard to the growing of wood and vegetables, and therefore what the position was in the growing of coal, for all vegetable matter had been produced by the aid of sun heat, and the plant had never been able to utilise anything like the 4·32 per cent. First of all, the visible spectrum of the sun was only a small proportion

of the whole energy of the sun, and then the green colour of the chlorophyll, which was the green colour of the vegetable, only absorbed out of the sun's spectrum a very small fraction of the visible spectrum, and it was only that which was available for decomposing the carbonic acid of the air and converting it into the cellulose of the plant; and it was only that which the world had ever had to rely upon for its production of wood and vegetables. Consequently all the coal available had so been produced. He could not remember what the proportion was, but it was considerably less than 4 per cent. He noticed a reference in the paper to one of the earlier inventors who talked glibly about concentrating the heat of the sun from an 85-ft. lens on to a single half inch diameter. That was a mistake which was very common. The idea was that the sun could be concentrated as much as one liked, and that all that had to be done was to make a lens big enough. For instance, if with one degree of concentration a temperature of 100 degrees was obtained, with 100 degrees of concentration 10,000 degrees of temperature could be obtained, and so on. The thing could not be done. The temperature of the sun could not be concentrated, for the reason that the diameter of the sun in the sky was, roughly speaking, half a degree, and any image produced by a lens had a definite size in relation to the size of the object. If a pocket lens were taken, that would make a minute image of the sun about as big as a pin's head, but if a large lens was employed it could not be put to the same distance. If one desired a large lens to gather much heat, it had to be put further off, and the moment that was done, although it was true that all the heat went on to the object put to receive it, the image of the sun ceased to be a thing like a small pin's head; it became larger. If a lens of 85 ft. in diameter were employed, the focus of such a lens would not be got nearer than 40 ft., and the diameter of the image of the sun would be one-hundred-and-twentieth part of that. One-hundred-and-twentieth part of 40 ft. was about 4 ins., so that the concentration of the inventor's lens of 85 ft. into an image ½ in. in diameter was on the face of it ridiculous and impossible. The author had referred to cooking by sun heat. That was an application of the heat of the sun which was far more easy and more economical than obtaining power, for the reason that, in cooking, a temperature was not required of more than the ordinary boiling-point of water and not a very great deal more than that for baking. So that moderate temperatures, which were easily obtained, were all that were required. Those moderate temperatures were not desirable when power was desired to be obtained, and that was where a real difficulty appeared—the difficulty of compromising in the sun-power plant. What was to be done? Was one going to work with a high pressure, which meant a high temperature, which meant considerable loss of heat from the boiler, in order to obtain great economy of such steam for producing power; or was one going to obtain the economy of not losing the heat from a very hot boiler, but lose it in more wastefully producing power? It had to be wasted in one way or the other, and on that question of waste the present view, both of Mr. Shuman and himself, was that all that had been done up to the present pointed to the desirability of obtaining higher pressure, and with it temperature in the boiler by somewhat greater concentration of the sun's heat; that was to say, a much larger amount of sun heat utilised in proportion to the surface of boiler heated. That brought him to another compromise. If there was very small concentration and a low temperature, one was so afraid of losing heat from the boiler that one or two glasses were put on. But supposing one went on increasing the size of the mirror in proportion to the size of the boiler; was that desirable? Supposing ten times as much heat was thrown on a boiler of a given size; if it was clothed with glass there would be reflected away by means of that glass ten times as much heat as was reflected away previously. That was not desirable, and it might be that, if only the degree of concentration were made sufficient, the increased loss due to not clothing might be less than the increased loss due to clothing, because the clothing of the boiler with glass would always reflect away a certain proportion of the heat, whereas the non-clothing of it would allow a fixed proportion for a given temperature and a greater proportion for a higher temperature. If possible, what was to be avoided was the loss as well as the inconvenience of the glass clothing, and that could best and most economically be done if only the concentration was amplified in a higher proportion than it was in the Egyptian plant.

Mr. R. W. Western said he understood the author to say that the sun-power plant, according to the latest developments, would be equivalent in a suitable climate to consumption in a steam plant of coal costing £3 10s. a ton. He presumed that estimate did not provide for depreciation of plant. The apparatus had not been in existence long enough to enable the author to have gauged what the depreciation would be, but it was no doubt large, as the plant covered a large area, was exposed to the weather, and the scantlings of which it consisted were small and would not last very long. That would be a serious drawback when comparing a solar plant with a steam plant. There was a further allowance which had to be made on the interest on the capital involved, because the obtaining of horse-power from a solar plant must involve a considerably larger capital expenditure than would be necessary to obtain it from coal. On the whole he was disappointed, because he had expected to hear that the prospects of a solar plant were rather more cheerful.

Mr. W. H. Massey said it was nearly sixty years ago since the first compound engine of which he had any knowledge was invented. The inventor was always impressed with the fact that it was much easier and more economical to cook by means of solar energy than it was to get power out of it. Several investigators, after experiment, came to the conclusion that the solar energy might be more usefully employed in the growing of vegetation, and he thought that conclusion was nearer the truth than the hopes expressed by the author. With regard to Tellier, who had been mentioned in the paper, he would like the author to say what sort of success, if any, had been obtained by Tellier.

Mr. Henry Jenkins said he had had the pleasure of hearing a paper on the same subject delivered by the author some little while previously at the Society of Engineers, and he had to confess that, as a prosaic engineer, he entered the room a little sceptical, but came out thinking very differently of sun power. As one who had seen some of the barer parts of the earth where the sun shone with great power, he could appreciate that the question of utilising sun power was getting rather close to practical politics. The amount of horse-power which had been obtained from a given area of plant in Egypt was considerable. The costs put forward, even supposing it meant that coal would have to cost £3 10*s.* a ton, in order to compete with other plant, were getting somewhere within the bounds of what could be paid in some places. For instance, in Sahara there had been a very marked desire for some time past to get a railway across the desert from Algeria down to our own railway in Nigeria. It was very important to be able to get water, which was known to exist at moderate depths below the surface in connection with that work, and a high price would be paid for a practical plant which would work by solar rays at those spots. In Chile the power had already been utilised. It had been demonstrated that low-temperature steam could, with suitable apparatus, be used to obtain quite appreciable quantities of water. He thought solar power was quite within the range of practical matters.

Mr. Walter F. Reid did not think it was quite fair to talk too much about capital, and the cost of reconstructing or keeping in repair apparatus of an experimental character, at the beginning of experiments. He did think stress ought to be laid on the fact that the sun was giving the source of the whole of the power for nothing, and when that was considered there was a very great margin left for the cost of machinery, the amortisation of capital, and so on. With reference to the Chairman's remarks, it was just possible that although a lens might not give an extremely good concentrated focus, one might do better with a mirror. He did not himself think the concentration—now that we had the electric arc and the oxy-acetylene blow-pipe, which would melt everything except carbon—of the sun's rays to the very highest temperature was a thing which was required particularly, except for scientific purposes. He thought the contrary direction ought to be taken. His opinion was that the use of water in a solar engine was a mistake. It was not a mistake in so far as it had yielded, as was seen in one of the photographs, a most ingenious boiler which was capable of being heated on both sides from a source of heat that came from one side only, but he thought the temperature of boiling water was so much above the temperature of the atmosphere that there was a very considerable loss from that alone. If a liquid were used which could be worked at a lower temperature, very much better conditions would be obtained for getting a higher yield from solar energy. With regard to the source of energy, he thought as a rule it had been accepted that the source of energy from the sun was uniform, but it appeared that that was not quite so. There was a variation. He thought the latest view of the sun was that it was a variable star, a star with a periodicity of 7 to 10 days. The heat varied from 7 to 10 days regularly, apart from the period of 11 years in which it was known to vary. The fluctuation was from 3 to 8 per cent. That was a matter to be considered, and no doubt further experiments would throw some light on it. There were means of finding out what was the actual radiation of heat from the sun by means of Fowle's spectrobolometer. By that instrument could be found out the total amount of vapour in the atmosphere between the earth and the sun, and the effect of the aqueous vapour on the transmission of heat being known, the loss through the presence of vapour could be exactly worked out. That was one of the great difficulties in our country—that there was too much vapour in the atmosphere. Even with a given amount of light it was never known how much heat was going to be got out of it. Personally he held the belief that the mechanical utilisation of solar energy would be a very great thing in the future.

Lieutenant-Colonel Allan J. C. Cunningham said a previous speaker had expressed the opinion that solar energy was better used in producing vegetation than in producing power, but he (the speaker) would like to point out that where solar energy was strongest was in hot dry climates, where vegetation could not be produced readily without plenty of irrigation; and where water was found it could only be got to the surface by some form of power. The question arose, therefore, of how to produce the necessary power for bringing it to the surface. It certainly seemed as if solar energy was being brought within measurable distance of utilisation in that connection.

Mr. C. Liddell Simpson said it had always been a question of study as to how the heat of the sun could be used. He remembered when he first

made a trip through India being struck with the amount of work which was done by the natives in raising water. If a suitable plant, worked by the heat of the sun, could be economically produced it would make a revolution in a great many of those arid deserts of India, where vegetation could only grow when irrigation was adopted. The plant at Cairo was most interesting, but the enormous space occupied by the boiler, in order to collect enough heat to give 100 h.p., seemed to put it out of the question as an ordinary commercial plant. The bodies to be interested in the matter were the Governments of India and Egypt, who should be urged to investigate the matter further in their colleges. Englishmen had given the question a good deal of study, but the thing which had held them back up to the present was that they could see no practical means of making the plant a commercial success.

Dr. John Pollen, C.I.E., said a more important subject than the one dealt with in the paper could not possibly be conceived in the interests of the people of India, and he trusted sincerely that engineers would not allow solar energy to go to waste.

The Author, in reply, said the first speaker had asked whether the figure of £3 10*s*. covered the cost of repairs and interest. The reply was in the affirmative—the £3 10*s*. covered everything. With regard to Mr. Tellier's success, he had read that gentleman's book, but could not find that he had ever made a plant; he gave most minute details of how to make one, but it could not be traced that he ever really did make one himself, and consequently he could not have experimented with it. He (the author) might mention that the best output of power per acre with the Meadi plant was on August 22nd, 1913, when there was 55½ h.p.—five times as large as had ever been obtained previously. It was equal to 63 b.h.p. per acre. The average for five hours of running on that day was 59 b.h.p. per acre, and the minimum was 52, so that the output was remarkably uniform.

On the motion of the Chairman, a vote of thanks was accorded to the author for his interesting and valuable paper.

ENGINEERING NOTES.

The War and the Railway Gauge.—The strategical importance of railways along a frontier is obvious, and, as an instance, we have the network of lines in East Prussia which has enabled the Germans to transport large bodies of troops from point to point, while the Russians, who do not possess such facilities, have found it difficult to cope with these rapid movements. The question of the difference of gauge, however, has not received the attention which its importance deserves. Outside the Pyrenees and a few unimportant places, the railway gauge throughout Europe is uniform, except in Russia, and therefore with that exception the operations of war in France, Great Britain, Belgium, Germany, Austro-Hungary, Servia, and Turkey, are untrammelled by any difference of gauge. The gauge in these countries is 4 ft. 8½ ins., in Russia it is 5 ft.—only 3½ ins. more—but it makes all the difference, and was so designed for strategical reasons. From a German and Austro-Hungarian point of view Russia is respectively on the offensive and the defensive, and is hampered by the change of gauge. Infantry and passengers tranship themselves, but guns, ammunition, cavalry, provisions, hospital stores, etc., excepting aero-craft, all have to be handled. Interruptions caused by the destruction of bridges, etc., which can always be repaired, are trifling in comparison with the obstruction due to a break of gauge. There are two points in connection with this matter, the fixed structures and the rolling-stock. The latter can take troops, etc., to the break of gauge, but if there is no train waiting to receive them they are blocked, which may or may not happen. The German advance in East Prussia against Russia, and the latter against Galicia, are on equal terms in that respect. One man's meat is another man's poison. In commerce, more or less disastrous results have followed from the divergence of gauge in India, South America, Africa, and Australia—in the last case the Government of the Commonwealth having appointed a committee who proposed unification at the cost of about £38,000,000.

Telephoning across a Continent.—Owing to public attention being so much engaged elsewhere, recent through telephoning from New York to San Francisco has escaped notice. Whoever has made this fascinating journey by train can picture to himself the varied climatic and scenic conditions through which the line passes, says a New York paper. The painstaking steps which have led to this final triumph need not be detailed here, but anyone with the most superficial knowledge of telephony must realise that it is the result of long and arduous research, of costly experiments in line construction, of profound studies in central office and substantial equipment, and of fatigue and of discomforts sustained by many men through heat and cold. It is hardly to be expected that trans-continental telephony will become a popular diversion at a cost of something like £5 for a three minutes' conversation between New York and San Francisco, but the amount of plant at the disposal of the subscribers, involving approximately 3,000 tons of copper wire and 130,000 poles, in addition to the transmitting and receiving apparatus, switchboard, auxiliaries, etc., explains to some extent the cost of a temporary exclusive right of way across the United States. Probably the greatest gain will be to users of intermediate toll service, and the linking of Chicago, Denver, and other cities, with the Pacific coast will do much to expedite important business by telephone, and tie together great areas until very recently only on the frontiers of this form of communication. It was a happy circumstance that the veterans Dr.

Alexander Graham Bell and Thomas A. Watson, participants in the first telephone conversation in the world some thirty-eight years ago, exchanged greetings over the new lines.

Large Diesel Engine.—The largest Diesel engine yet constructed to a definite order, states the *Times*, has recently been completed by Messrs. Sulzer Brothers, of Winterthur, Switzerland, and successful tests have been carried out. Motors of higher power have been built by two firms in Germany, but up to the present they have reached only the experimental stage. The new engine is of the two-cycle single-acting type, with six cylinders, and was designed to develop 3,750 b.h.p. at 142 r.p.m., though on trials a power of 4,500 b.h.p., or about 750 b.h.p. per cylinder, was maintained for a long period. It was built for Messrs. Harland and Wolff, of Belfast, and is to be employed in generating electricity for light and power in the shops, although there is a possibility that its installation may lead to a similar type of motor being developed for marine work in this country. The cylinder dimensions are 750 mm. bore and 1,000 mm. stroke (about 29·5 ins. by 39·4 ins.), and in general design the motor is of the marine type, being somewhat similar to the 850 h.p. engines installed in the motor-ship "Monte-Penedo," and also to two sets of 1,600 b.h.p. each, built for a British naval tank ship. There are two scavenge pumps driven directly off the crank shaft, and the scavenging air is admitted to the working cylinders through two sets of ports at the bottom. The main ports are opposite the exhaust ports, and occupy half the periphery, while the auxiliary scavenging ports are above, the air being admitted to them after the piston has covered the bottom set in its upward stroke. For each cylinder there is a valve in the main scavenging pipe controlling the passage of the air to the auxiliary ports. The cylinder covers are supported by means of steel columns, which take the main stresses due to the high pressure, and the cylinders are hung from the covers, being therefore free to expand longitudinally. Another modification is that the governor of the engine is arranged to control the air inlet of the air-compressor and the time of opening the fuel valve, as well as the stroke of the fuel pump. By this means the engine is enabled to run satisfactorily at low powers.

Painters' Colours and Materials.—Germany will lose heavily through the war in this particular trade. In 1912 Germany, says the *Engineer*, exported to all destinations, painters' colours and materials to the value of £3,162,000. This country was by far the best customer of Germany for these goods, the exports to the United Kingdom being £791,000, or 25 per cent. of the total. This market is now lost to Germany, and the loss is likely to be a permanent one, as British paint and colour manufacturers, says a contemporary, are now successfully making almost all the materials which hitherto have been supplied from the Continent. It may safely be assumed that Germany's paint and colour trade with British possessions, which amounted in 1912 to over £80,000, will now be transferred to this country. It is also reasonable to suppose that our manufacturers will be able to capture a large proportion of Germany's trade with France in similar goods, amounting to £180,000, and with Russia, amounting to £150,000. Germany is also cut off from the United States market, to which in 1912 she sent paints and colours to the value of over £300,000, and from the South American markets to which her exports of the same class were of the value of £120,000. In these markets British manufacturers have openings and opportunities such as they never had before, and are not likely to have again.

Concrete in Waterworks Construction.—Amongst other things, the behaviour of water in concrete is constantly mooted, and the following, recently read by Professor Edgar B. Kay, a leading authority on the question, to the American Waterworks Association, will be read with interest. The quotation is from "Ferro-Concrete":—

"*Sand.*—Tests have shown conclusively that sand with rounded grains makes quite as strong a mortar, other things being equal, as does sand with angular grains. A fine sand makes a weaker mortar than a coarse, because of the lower density. The only substitute for natural sand for concrete that need be considered is pulverised stone, either dust and fine screenings produced in crushing rock, or an artificial sand made by reducing suitable rocks to powder. *Stone Dust.* -- The danger of using stone dust is failure to secure the proper balance of large-sized grains. The coarseness as well as the fineness of a good concrete sand is limited. The best sands will show not more than 40 per cent. retained on a No. 10 sieve, and not more than 5 per cent. passing a No. 80 sieve. *Grading Aggregates.* — Upon large or important structures it pays to make careful studies of the materials of the aggregates and their relative proportions. Mr. W. B. Fuller has shown that by changing the ordinary mixture of watertight concrete, and by carefully grading the materials, he was able to obtain watertight work while effecting a saving of 0·36 barrel of cement per cubic yard of concrete. *Watertight Concrete.*—A wall of concrete may be rendered watertight by accurately grading and proportioning the aggregates and the cement. For maximum watertightness, a mortar or concrete may require a slightly larger proportion of fine grains in the sand than for maximum density or strength. In general it may be stated that in monolithic construction a wet mixture, a rich concrete and an aggregate proportioned to secure great density, will in the majority of cases, give the desired results." This method is unquestionably the best to secure watertightness, and the Professor is not in favour of using waterproofing ingredients or of making surface applications except in cases where they may be required by reason of imperfections in the original concrete.

GENERAL NOTES.

Chinese Market for Machinery.—The following articles imported from Hankow have, according to H.M. Consul-General at that port, hitherto been largely of German or Austrian origin: Machinery of all kinds, small tools, hardware, such as galvanised, corrugated, and flat sheets, wire nails, rods and bars of various sections, window glass, nail rods, copper and brass bars, and sheets, needles, Berlin wool, braid, buttons, ribbons, trimmings, lamps, soaps, wash-basins and enamelled ware, aniline dyes, chemical products, electrical material and fittings, cups and saucers, and generally small metal goods of inferior quality and low price. German manufactured piece-goods and fancies imported at Hankow consist chiefly of cheap waste-cotton printed blankets and small sundries such as baby-caps, men's vests, caps and hats, etc. Cotton trouserings are imported also from Austria and Italy. Most of the trade in imported goods is done with dealers in Hankow, and the exploitation of the interior and treaty ports further removed from the coast is left entirely to them. There is no doubt that the business could be much expanded if this exploitation could be undertaken to a larger extent by foreigners. The (merchant) firms in China are not in a very good position to do this, unless they are materially assisted by manufacturers and exporters at home. Some goods, of course, lend themselves better than others to this treatment. Certain firms have been very successful in organising up-country agencies under Chinese merchants for the sale of sowing machines, knitting machines, patent medicines, and the like. Many other articles could also find an extended market in this way. It would, of course, be essential that the goods should be sent out on consignment to agents. German manufacturers seem to be more alive to the requirements of the Chinese market, and to be more willing to assist the merchant on the spot. The machinery trade affords an example of this. Much machinery of British origin has been imported through German firms, but the latter also represent German manufacturers, and are naturally prone to push German in preference to British goods wherever possible.

Indian Crops.—The April number of the *Bulletin of Agricultural and Commercial Statistics* publishes figures for the crops recently harvested in India. The wheat crop for 1914–15 was 104,581,718 quintals, 123 per cent. of that for the preceding season. The rice harvest is estimated at 284,125,351 quintals of husked rice as against 292,522,979 quintals in 1913–14, or 97 per cent., and the yield of cotton was 9,492,752 quintals as against 9,189,733 in 1913–14, or 103 per cent.

Wheat in Burma.—Recent experimental work in Burma encourages the hope that in years to come this country will be numbered among the wheat-producing provinces. From the annual report of the local agricultural department for 1914 it appears that work in connection with selection of wheat for seed purposes has been carried on at Mandalay, and that the farms at Padu in the Sagaing District and Hopin in the Myitkina District will enable this crop to be taken up in earnest. It is satisfactory to learn that success has been obtained as far north as Myitkina, and the hope is expressed that the introduction of this new staple to the cultivator of Northern Burma will not be long delayed. In the Shan States no great developments are to be expected until the completion of the railway to Yawnghwe, but thereafter large areas should come under wheat, as the soil and climate are favourable. The farms of the agricultural department will find out what types are specially suitable for cultivation.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

May 5. — Augustus Vernon Harcourt, D.C.L., LL.D., D.Sc., F.R.S., "On the Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate." Francis William Goodenough, M.Inst. Gas Engineers (Gas Light and Coke Co.), will preside.

May 12.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry." Sir Robert Abbott Hadfield, D.Sc., F.R.S., will preside.

Additional Lecture.

Thursday afternoon, at 4.30 o'clock:—

May 6.—M. Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Constantin Meunier et les Sculpteurs Belges de son Temps." Lord Sanderson, G.C.B., K.C.M.G., will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

May 13.—Sir Charles H. Armstrong, late Chairman, Bombay Chamber of Commerce, "Indian Trade and the War." The Most Hon. the Marquess of Crewe, K.G., P.C., Secretary of State for India, will preside.

Colonial Section.

Tuesday afternoon, at 4.30 o'clock:—

May 4.—S. Chas. Phillips, M.S.C.I., "The Empire's Resources in Paper-making Materials." The Hon. Sir George H. Perley, K.C.M.G., Member of the Canadian Government, will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

David Sommerville, B.A., M.Sc., M.D., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Syllabus.

Chemical Constitution of Foodstuffs—Proteins—Carbohydrates — Fats — Inorganic Substances — Colloids and Crystalloids—Metabolism—Enzymic Action in the Alimentary Canal.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 3 ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. D. Sommerville, "Foodstuffs." (Lecture II.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. W. St. Clair Tisdall, "Mahâyâna Buddhism and Christianity."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m.

Surveyors' Institution, 12, Great George-street, S.W., 7 p.m. (Junior Meeting.) Annual General Meeting.

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Annual General Meeting.

Tuesday, May 4...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. S. C. Phillips, "The Empire's Resoures in Paper-making Materials."

Rontgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m.

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Professor Inayat Khan, "Indian Music," accompanied by the "Royal Musicians of Hindustan."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Animal Spirits." (Lecture I.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Dr. W. H. Workman, "The Mountaineering Aspect of Himalayan Glaciers."

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. 1. Annual General Meeting. 2. Professor Haverfield, "Roman Conceptions of Empire."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Dr. F. Penrose, "The Use of Autochromes in Bird Photography with Examples of Protective Coloration."

Wednesday, May 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. A. V. Harcourt, "The Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate."

Civil Engineers of Ireland, Institution of, 35, Dawson-street, Dublin, 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. Joint meeting with the Biochemical Society to discuss the "Methods adopted in the Estimation of the Nitrogenous Constituents of Extracts derived from Albuminous Substances, such as Meat Extracts and similar products, with special reference to the interpretation of the results."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. A. H. Allcroft, "Some New Light on Roman Roads in Sussex."

Thursday, May 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Special Lecture.) M. Paul Lambotte, "Constantin Meunier et les Sculpteurs Belges de son Temps."

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. W. P. Westell, "Some Bird Problems." 2. Dr. Sarah M. Baker and Miss M. H. Bohling, "On the Brown Seaweeds of the Salt-Marsh." (Part II.) 3. Mr. H. N. Dixon, "On a collection of Borneo Mosses made by the Rev. C. H. Binstead." 4. Rev. T. R. R. Stebbing, "Photographs of a curiously-grown tree from a Tunbridge Wells garden."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Messrs. T. M. Lowry and T. W. Dickson, "The rotatory dispersive power of organic compounds. Part VI.—Complex rotatory dispersion in ethyl tartrate." 2. Messrs. T. M. Lowry and H. H. Abram, "The rotatory dispersive power of organic compounds. Simonsen and M. Nayak, (*a*) "The nitration of 3-acetylamino-2-methoxy toluene"; (*b*) "Condensation of ethyl cyanoacetate and acetyl acetone."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. W. Porter, "Advances in General Physics." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. T. E. Peet, "Abydos, an Egyptian Sacred City."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. 1. Annual General Meeting. 2. Discussion on Mr. O. C. Hill's paper, "The London Building Acts with some suggested Amendments."

Friday, May 7...Royal Institution, Albemarle-street, W., 9 p.m. Professor O. W. Richardson, "Electrons and Heat."

Historical Society, 22, Russell-square, W.C., 8.30 p.m. Mr. H. J. Mackinder, "The Historical Geography of the Hungarian Plain."

Geologists' Association, University College, W.C., 8 p.m.

Textile Institute, 16, St. Mary's Parsonage, Manchester. Annual Spring Meeting and Conference.

Saturday, May 8...Royal Institution, Albemarle-street, W., 3 p.m. (Tyndall Lecture II.) Professor J. A. Fleming, "Photo-Electricity."

Journal of the Royal Society of Arts.

No. 3,259. VOL. LXIII.

FRIDAY, MAY 7, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 10th, 8 p.m. (Cantor Lecture.) DAVID SOMMERVILLE, B.A., M.Sc., M.D., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, "Foodstuffs." (Lecture III.)

WEDNESDAY, MAY 12th, 8 p.m. (Ordinary Meeting.) CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry." SIR ROBERT ABBOTT HADFIELD, D.Sc., F.R.S., will preside.

THURSDAY, MAY 13th, 4.30 p.m. (Indian Section.) SIR CHARLES H. ARMSTRONG, late Chairman, Bombay Chamber of Commerce, "Indian Trade and the War." The Most Hon. the MARQUESS OF CREWE, K.G., P.C., Secretary of State for India, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, May 3rd, DR. DAVID SOMMERVILLE, B.A., M.Sc., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, delivered the second lecture of his course on "Foodstuffs."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, May 4th; The Hon. SIR SIR GEORGE H. PERLEY, K.C.M.G., in the chair. A paper on "The Empire's Resources in Paper-making Materials" was read by Mr. S. CHAS. PHILLIPS, M.S.C.I.

The paper and discussion will be published in a subsequent number of the *Journal.*

EXAMINATIONS, 1916.

The arrangements for 1916 will be similar to those of 1915, and two examinations will be held in all three stages. The first examination will commence on April 10th, and finish on the 19th. The second will commence on May 29th, and finish on June 7th. The last days for receiving entries will be March 13th and April 28th.

The time-tables will be published later.

BARRY'S PICTURE OF "ADAM AND EVE."

The picture of "Adam and Eve," by James Barry, R.A., which has been on loan at the South Kensington Museum (now the Victoria and Albert Museum) since 1856, has been presented by the Society to the National Gallery of Ireland, and has been accepted by the Governors and Guardians of that Institution.

Barry was born in Cork, in 1741. His principal work is the series of paintings in the Society's Meeting Room, and not many of his other paintings are now known to be in existence. There are very few specimens of his work in any of the London public galleries, and these are all portraits. There is an unfinished portrait of Dr. Johnson in the National Portrait Gallery, evidently a study for the portrait in the group in the artist's picture, "The Society." There are also portraits of himself in the Victoria and Albert Museum and in the National Portrait Gallery.

The "Adam and Eve" was painted in Rome, and was exhibited, after Barry's return to England in 1770, in 1771 at the Royal Academy, this being the first picture shown by him at the Academy. When, after his death, his works were sold at Christie's in 1807, the "Adam and Eve" was purchased for 110 guineas. The name of the purchaser does not appear to have been recorded. The Society possesses an etching of the picture by

Barry. The title is given on the plate as "The Temptation of Adam."

In 1834 the picture was presented to the Society by Mr. Richard Horsman Solly, and the following entry appears in the Society's Minutes under the date of November 12th, 1834:—

"A letter was read from R. H. Solly, Esq., stating that he had sent to the Society for exhibition on Tuesday (the evening of the first Illustration this Session) a picture painted by the late James Barry, Esq. (Adam and Eve), and should the Society wish to possess it, he should have much pleasure in presenting it to them.

"A motion was made by Mr. Moore, and seconded by Mr. Winkworth, that the warmest thanks of this Society be presented to Mr. Solly for this additional proof of his liberality and good wishes towards the Society."

Mr. R. H. Solly, who died in 1858, was a very active member of the Society, and it was due mainly to his exertions that the Society from 1831 onwards did a great deal to encourage improvements in the construction of telescopes and microscopes.

PROCEEDINGS OF THE SOCIETY.

NINETEENTH ORDINARY MEETING.

Wednesday, May 5th, 1915; FRANCIS WILLIAM GOODENOUGH, M.Inst. Gas Engineers (Gas Light and Coke Company), in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Amenomori, Kikutaro, Nakanocho, Higashi-Sambongi, Kyoto, Japan.

Armstrong, Sir Walter, Hon. R.H.A., 63, Carlisle Mansions, Victoria-street, S.W.

Grant, Alfred Charles, Montego Bay, Jamaica, British West Indies.

Khan, Haziq-ul-Mulk Hakim Mahomed Ajmal, K.I.H., President, Anjuman-i-Tibbia, Delhi, India.

Mishra, Pandita Damodardas, Hardwar, United Provinces, India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Baw, U. Kan, K.I.H., Pyinmana, Yamathin District, Burma.

Bright, Charles, F.R.S.E., M.Inst.C.E., M.Inst. E.E., Members' Mansions, Victoria-street, S.W.; and The Grange, Leigh, Kent.

Griffin, Louis T., The Auckland Museum, Auckland, New Zealand.

Humphrys, Claude William Erskine, Penang Rubber Estates Co., Ltd., Province Wellesley, Penang, Straits Settlements.

The paper read was—

ON THE MEASUREMENT OF THE EFFICIENCY OF DOMESTIC FIRES, AND ON A SIMPLE AND SMOKELESS GRATE.

By AUGUSTUS VERNON HARCOURT, D.C.L., LL.D., D.Sc., F.R.S.

Several months ago a friend told me that he had got a box of some stuff which would make one ton of coal go as far as two. Would I come and see it tried?

I found that the box was a cardboard box holding about half a pint of a pink powder. A heaped teaspoonful of the powder was to be stirred up in a pint of water and three scuttles full of coal sprinkled with this mixture. The disproportion between the size and number of the lumps of coal and the teaspoonful of powder which was to be distributed over their surface was so great that it was difficult for anyone whose business has been experimental chemistry to go through this sprinkling seriously. However, it was done, and has been done for me many times since. But neither then nor in subsequent trials, using a grate well adapted for such observations, could any material difference be found in the rate of burning with and without the powder. What difference there is seems to be due to the water, which is used as a means of distributing the powder. If coke be thoroughly wetted, it absorbs a large volume of water, and the life of the fire is much lengthened; with a feeble draught it might even be doubled; but with lumps of coal the effect is much less.

Since the pink powder consists chiefly of common salt, the effect of dissolving a quantity of salt in the water was tried, but no further diminution in the rate of combustion was observed.* A salt more fixed in the fire, such as sodium sulphate, would doubtless be more efficient; but some heat is lost if coal or coke is wetted, and in an open grate neither needs to have its combustibility diminished unless there is an unusually strong draught. When this is the case, an admixture of breeze or small coal, of which there is generally more than

* An analysis of the powder made for me by Mr. R. E. Steel, Natural Science Master at Sherborne School, gave the following result:—

Sodium chloride	83·85
Calcium carbonate	8·71
Ferric oxide	2·88
Silica	0·69
Water	3·57
	99·70

enough in a coal cellar, will check the draught and reduce the rate of burning.

There remains the question of the output of heat. Chemists, and, indeed, everyone who has a little knowledge of chemistry, will agree that the total amount of heat caused by the combustion of a pound of coal will not be increased by the addition to it of rather less than one grain—that is, one seven-thousandth part—of any kind of incombustible material.* But it may be rightly objected that it is not the total amount of heat which concerns the householder, but the amount of heat radiated into a room, and this cannot be so easily and exactly measured. A minute proportion of common salt in the air around an atmospheric burner enormously increases the light radiated from it. Why should not the same agent cause some corresponding increase in the heat radiated from a lump of coal?

The desire to settle this question, by measuring the amount of heat radiated into a room, led me to design, and have made, a little instrument for the purpose, and, having worked with it, to offer to your Society an account of the instrument and the results, and at the same time to bring before you a form of grate, the more remote and the immediate ancestors of which have added to my comfort for some forty years, but whose efficiency with various fuel I have only measured in the last few months.

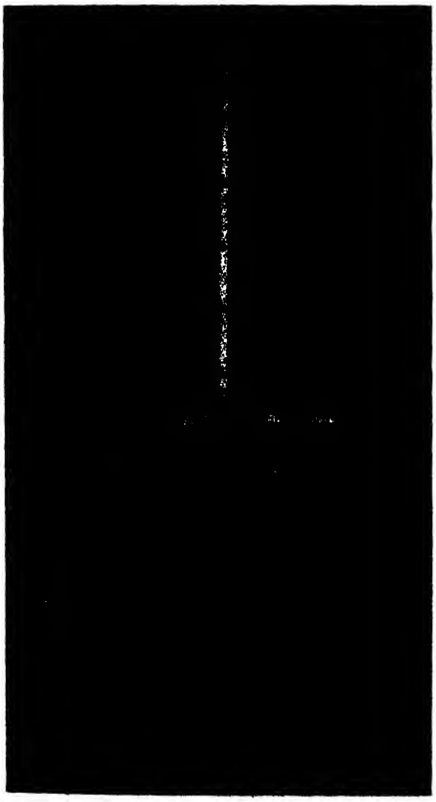

FIG. 1.—THE RADIO-THERMOMETER.

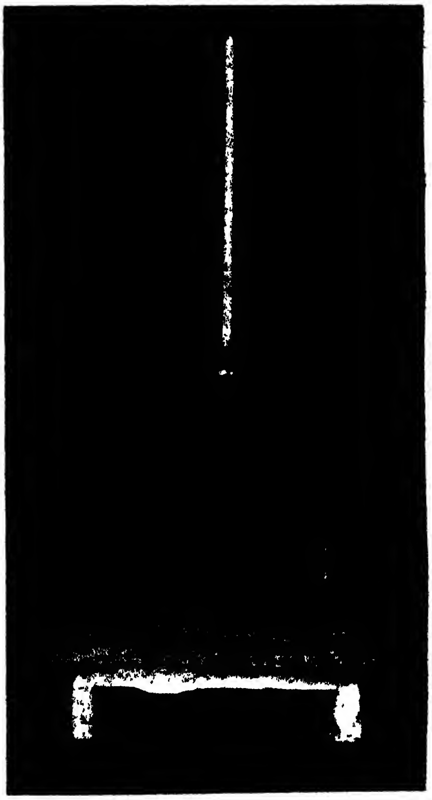

FIG. 2.—COPPER BOX OF RADIO-THERMOMETER, WITH WOODEN BOX AND PACKING BENEATH.

The instrument which, for want of a shorter name, I call a radio-thermometer—that is, measurer of radiant heat—consists of a copper box, 6 ins. × 6 ins. × 1 in., with a small funnel-shaped inlet, enclosed in a wooden box, 7 ins. × 7 ins. × 2 ins., open at the top and with an opening 5 ins. square in the middle of one side. Except on this side there is a space between the two boxes, of an inch at the back and half an inch at the sides and below, which is loosely packed with cotton-wool. Of the side which is in contact with the wood the central 25 square inches is exposed and has been blackened. A

* One heaped-up teaspoonful is to be sprinked over one hundredweight of coal or coke. Four heaped-up teaspoonfuls weigh about one ounce, whence approximately 64 weigh one pound, and 7,168 one hundredweight.

thermometer is held by a cork in the opening at top, and this is also used as a stirrer, being furnished with a cup-shaped piece of rubber sheet tied on above the bulb, which stretches across the box.

The weight of the copper box is 11 oz., that of the water which fills it is 1 lb. 6 oz. The water-equivalent of the copper box is 11 × ·095 = 1·045 oz. Hence the mass of water heated may be taken as 1 lb. 7·04 oz., or 1·44 lb. The instrument having been freshly filled with cold water, is placed facing the middle of the fire at a distance of 3 ft. Exactly at some minute by the watch the thermometer is read. About nine

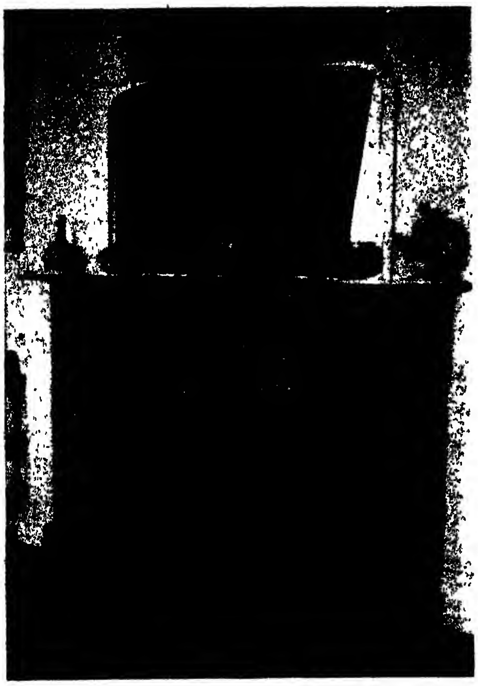

Fig. 3.—A Grate in which the Fire is drawn up by hanging plates.

minutes later the water is briskly stirred up and down with the thermometer, which is then replaced with its bulb central, and at the end of ten minutes the thermometer is again read. These readings are repeated every ten minutes until the temperature of the water is as much above the temperature of the air, taken by a thermometer at the back of the instrument, as it was below it at starting. The cotton-wool, which checks the flow of air round the box, prevents the temperature of the air of the room having much influence, and both this and the exchange of radiations are approximately balanced by the temperature of the water being to an equal extent, and for nearly the same time, first lower, then higher, than that of its surroundings.

A set of observations thus made generally occupies nearly an hour, and gives an average result for that period. To make the results, when at different times the fire was larger or smaller, more comparable, an estimate was made, every ten minutes, of the area of fire from which the chief part of the heat was being radiated, as being so many spaces. The bars being 18 ins. long with 2 ins. between them, a space was 36 square inches. Though each estimate was only approximate the average will not have been far wrong.

An example will show the plan which has been followed:—

February 25th, 1915. Barometer, 30·2. Temperature of air in room, 57°·0. Grate charged with coke. Fire lit at 8 a.m.

Time.	Temp.	Rise in 10 mins.	Spaces.	Balance of Temperatures.	
	°F.	°F.		°F.	°F.
IX. 26	35·8	..	3·0		
36	41·6	5·8	3·3	57·0	78·5
46	48·0	6·4	3·5	35·8	57·0
56	54·7	6·7	4·0	21·2	21·5
X. 6	62·2	7·5	4·3		
16	70·4	8·2	5·0		
26	78·5	8·1	5·0		
Average . .		7·12	4·0	Average rise for 1 space	1°·78

The heat radiated from 36 square inches of fire-front, corresponding to a square 6 inches in the side, upon a surface of 25 square inches, at a distance of 3 feet, in ten minutes, raised the temperature of 1·44 lb. of water 1°·78 F. Since all these measures but the last are constants of the method, the result may be called 1·78 units.

If these units, which serve for the comparison of one grate or one fuel with another, are multiplied by 25·2, the total amount of heat sent into the room every minute from each 6 inches square of the front of the fire, is given in British Thermal Units.*

* $\frac{1\cdot44\times175}{10} = 25\cdot2$. Multiplication by 1·44 increases the result to what it would have been if only 1 lb. of water had been heated. Division by 10 reduces it to what it would have been if the heat had only been applied for one minute. 175 is an approximate estimate, furnished me by Mr. Sydney Lupton, of the number by which the heat falling normally upon a surface of 25 square inches must be multiplied to represent the total heat radiated in front of the fire in every direction.

A large number of measurements have been made of heat radiated from coal and from coke, and from coke which had been wetted, and from coal and coke treated with the pink powder in the manner prescribed. The grate chiefly used was that of which I have here an example, whose division into many spaces and flat vertical front adapt it for this purpose. The whole charge of fuel is put in at once, and heaped up above the top bar into the throat of the chimney before the fire is lit. The fire burns gradually downwards, like a candle, and lasts the day through.

The average results, in units of the method, are as follows: Coke, 1·97; coal, 1·63; wet coke, 1·29; coke or coal sprinkled with water and powder, 2·03. The numerical results are given, but must only be regarded as rough approximations indicating little more than the order of magnitude. The precaution was taken of allowing the fire to burn for some time before measurements were made, both that the chimney might have attained its full temperature, and that a sufficient space might intervene between the top of the fire and the opening of the chimney to lessen the effect of the draught up the chimney. Even so, the effect of wind—and probably also, though in a less degree, of outdoor temperatures and moisture—is such that observations would need to be made over a long period if a more accurate average were necessary.

The actual results are intelligible and probable. Coal when it burns passes through two distinct stages. First it gives off gas, some of which burns, while some, not coming in contact with anything sufficiently hot or being mixed with too much steam or nitrogen, escapes unburnt. When evolution of gas has ceased the coal has been changed to coke, and the second stage begins. Thenceforward it burns with a steady glow. Much less heat is radiated out during the first stage than during the second; the heat from the burning gases goes chiefly up the chimney. Thus when the heat from a coal fire is fairly measured, some parts being in one stage and some in the other, the result is lower than when all is in the second stage or, which is the same thing, when coke is being burnt. Wet coke, if sufficiently wet, gives still less heat at any moment, for it burns more slowly and some of its heat goes to evaporate the water. When the fire is dull-red the steam from water beneath escapes and makes no sign, but when the upper part is glowing brightly the steam is successively decomposed and recomposed, the pale flame of hydrogen, though mixed with an equal volume of carbonic oxide, being distinguishable from the blue flame of carbonic oxide, which air without steam produces.

Coke treated with powder or untreated radiates practically the same amount of heat, a result which will not surprise members of this Society.

I remember another little box much in demand sixty or more years ago. It was filled with little bottles containing homœopathic globules which good people took and gave to their friends, having a confident belief in the

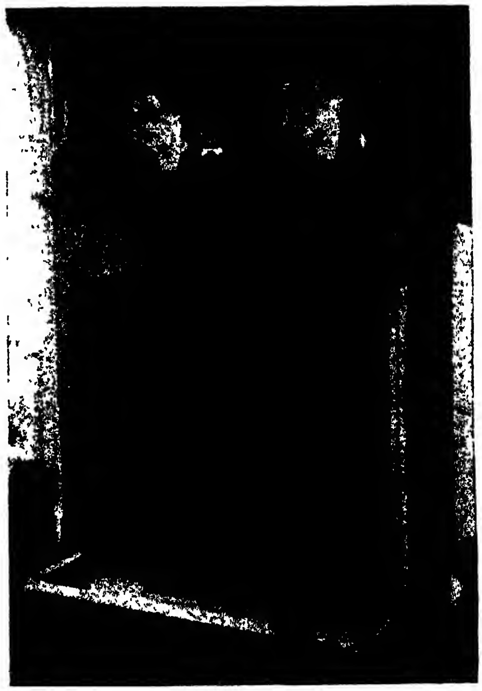

Fig. 4.—A Grate charged and ready for Lighting.

benefits which followed. In that case, as with other more plausible drugs, the belief could not readily be put to the test of comparative experiment. In the case of a physical agent, this test is readily though not commonly applied. It seems that we are not wiser than were, according to Mr. Kipling, "Our fathers of old."

Bulk for bulk, coal is nearly twice as heavy as coke, burns for longer under the same conditions, produces more heat, and from an open grate radiates rather more heat, because it lasts longer.

Weight for weight, coke has the advantage for domestic use, and would retain it even if through increased demand the price of the two were the same.

If public benefit can be brought into account, the advantage of the use of coke for domestic fires is very great. The fires are smokeless. I hope some member of the Smoke Abatement Society may be here who will tell us how London and other great residential cities and towns would benefit if the chimneys of houses sent out no smoke. Nearly one-quarter of the coal consumed in the United Kingdom is burnt in domestic fires.

The grate of which, in conclusion, I have still to give a description, or rather one of its predecessors on the same principle, was used with coal only for many years, and used to be nearly smokeless after the first hour. By that time the top layer of coal had passed through its first stage of flame and smoke, and had become a layer of glowing coke. Through this layer the gases given off as the heat spread to the coal beneath, with their light burden of particles of soot, had to pass on their way to the chimney; all that was combustible, whether gas or soot, was burnt, and thenceforward for the rest of the day the fire was smokeless. A few years ago it occurred to me that it might be well to mix coke with the coal; the proportion of coke was gradually increased, and latterly I have used coke only, excepting that for lighting the fire a few pieces of coal are helpful, as well as paper and wood.

Where a fire is needed for a short time only a gas fire is best. One of these, with good pressure and a consumption of about 35 cubic feet of gas per hour, gave as much heat as three spaces of the coke fire, or as a good drawing-room fire of the ordinary type. For equal times of burning, the cost of the gas fire is much greater. The charge of coke which fills the grate and maintains a good fire for fourteen hours, as from 8 a.m. to 10 p.m., is 34 lbs., which, with coke at a peace price of 18*s.* per ton, costs only 3¼*d.* Gas giving as good a heat, and burning at the rate of 35 cubic feet per hour for the same time, would, at the rate of 2*s.* 6*d.* per thousand cubic feet, cost nearly 1*s.* 3*d.* But when a fire is needed for only half an hour or an hour, as in a dressing-room, the immediate lighting and extinguishing, together with the

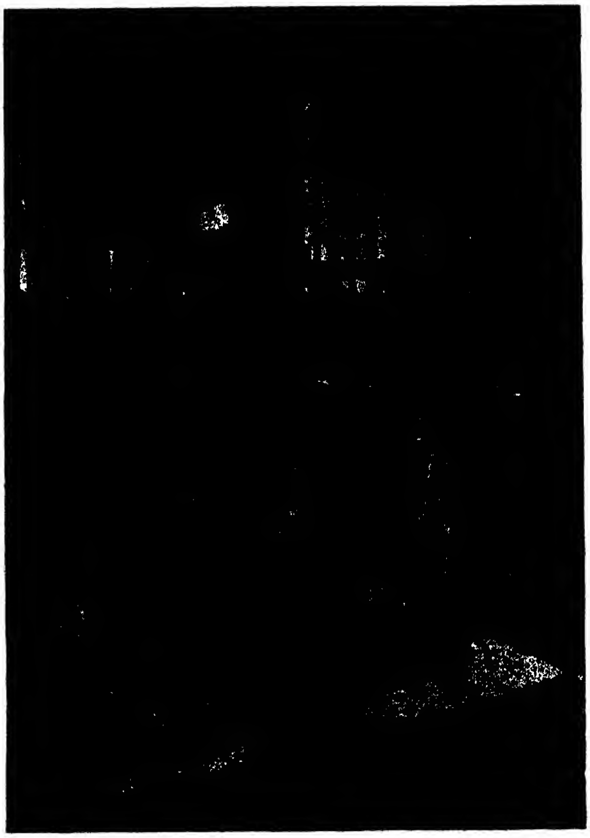

FIG. 5.—GRATE WITH SURROUNDINGS.

absence of all trouble of emptying ashes, cleaning, laying and lighting, turns the scale in favour of gas.

In the construction of a grate to yield as much radiant heat as possible from the fuel consumed, certain principles should be observed: (1) The face of the fire should be vertical, so that the chief radiation should be horizontal, not directed upwards towards the chimney and the ceiling; (2) the bars should be as slight as is compatible with sufficient strength, and as wide apart as will suffice to prevent more than an occasional ember falling out; the reason is that the bars do not reach a red heat, nor radiate so much heat as an equal surface of the fire behind them, and to the extent of the difference they act as screens; (3) for a similar reason the fire should be narrow from back to front. A space of 4 or 4½ inches between the back and the bars is enough; only the glowing surfaces which can be seen from in front radiate heat into a room, and lumps of fuel which hide other lumps and the red-hot firebrick behind them, act as screens, whether they themselves are dark or glowing; (4) air should pass in through bars in front, not through bars beneath; for the most vivid combustion occurs where the air and fuel meet. If this is at the bottom of the fire, much heat is radiated on to the hearthstone below, and helps to send a current of heated air up through the fire, promoting the burning of the coal, but not to good purpose; (5) to save the trouble of frequent attention and replenishing from a coal-scuttle during the day, and to avoid smoke, it is well to put in at once all the fuel the fire will need and to light it at top; (6) coke burns down more quickly than coal, and thus, especially with coke which has been "graded" and the light combustible coke from vertical retorts, the fire may reach its full heat near the middle of the day when its services are less needed than earlier or later. Control of the fire can be obtained by means of an iron plate put in when the fire is being laid, half-way up, resting on two or three lumps of coke only, that air may circulate underneath and prevent it becoming so hot as to ignite the coke beneath. When the fire is low the plate is pulled out, and the lower half of the fire makes a fresh start; (7) some means are needed for drawing up the fire when it is low. Either plates may be hung on one beneath the other, or folding doors may be arranged to close the upper part of the grate,

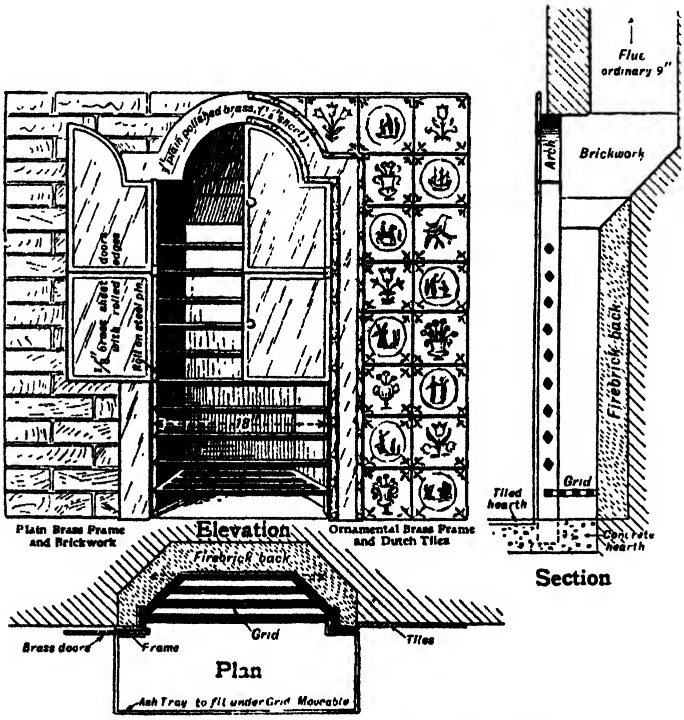

FIG. 6.—DESIGN OF FLAT GRATE BY MR. KITCHIN.

and so concentrate the pull of the chimney upon the face of the fire beneath.

The grates, of which various illustrations will be shown, have been constructed on these principles. A serious difficulty has had to be met, for which there is no scientific solution. The grate must not be less attractive in appearance than other grates. Its simple character and the unavoidable display of a large unrelieved surface of coke or coal make this difficult. I appealed, but unsuccessfully, to a well-known artist who has professed a keen interest in smoke abatement. More recently, I have communicated my ideas to an architect, Mr. George Herbert Kitchin, of Winchester, of whose taste and skill I have had experience, asking him to do what was possible towards producing an attractive design and to arrange for the manufacture of grates in accordance with his design.

The illustrations I have to show are: (1) Of grates of this kind as they have been in use in my house for many years past; (2) of Mr. Kitchin's designs, embodying some recent improvements in construction as well as in appearance.

The second of the two, which has the disadvantage of departing still further from established forms, will utilise a still larger proportion of heat from the fuel consumed. The charge of fuel compared with that of the flat grate is nearly the same, namely, as 75·4 to 72, the front of the fire, with whose area radiation varies, is as 25 to 18, or one-third greater. The back of the grate is formed by an eight-inch pipe of iron, or perhaps better of fire-clay, admitting air below and discharging it into the room at the level of the top of the fire. Much heat is thus utilised which would otherwise pass up the chimney.

Which of the two designs is better looking, or whether either is sufficiently good looking, are questions on the answers to which their future usefulness, for which I hope, must largely depend.

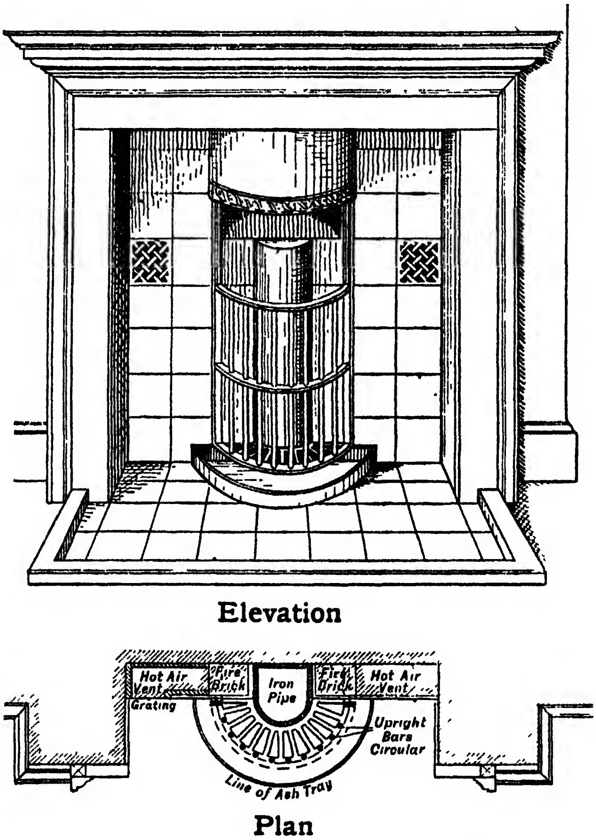

FIG. 7.—DESIGN FOR A SEMICIRCULAR GRATE IN WHICH HOT AIR FROM THE BACK OF THE FIRE PASSES INTO THE ROOM.

DISCUSSION.

THE CHAIRMAN (Mr. Francis William Goodenough), in opening the discussion, said the paper contained at the beginning a surprise which was not indicated by the title, and that was the way in which the author courageously exposed certain claims which had been made upon the public credulity in regard to the influence of a certain powder upon coal. The analysis of the powder which the author gave agreed very closely with a similar analysis of such a powder which had been published in one of the technical journals of the gas industry some short time ago. With regard to the benefit which would accrue to cities and towns by the abolition of smoke from domestic and factory chimneys, he (the Chairman) was an enthusiastic member of the Smoke Abatement Society, but he did not think he would be equal to explaining the magnitude of that benefit. As had already been pointed out, the result of the diminution of smoke from domestic and factory chimneys in London in recent years had been to increase the average hours of sunshine by something like eighty per annum; and when one remembered the vitalising effect of sunshine it was not easy to measure, but not possible to doubt, the advantage which would accrue to London from a further diminution, and finally a complete abolition, of the smoke nuisance. The comparisons which had been published by authorities like Dr. Saleeby between the lungs of the town dweller and the lungs of the country dweller were eloquent of the damaging effect of the smoke and gases given off by the crude fuel burnt in our grates and under our boilers. As the author had indicated, the solution of the smoke trouble was the use of coke and gas. In a recent paper read before the Society, Mr. H. M. Thornton had shown the extent to which coal gas had displaced the cruder form of fuel for industrial purposes, and everyone knew the rapidity with which gas had taken the place of coal in domestic use. The exhibition of the coke fire which the author had given that night, and his testimony as to its satisfactory use in his house for so many years, would, he (the Chairman) should think and hope, lead to a considerable increase in the use of coke for domestic purposes. In fact the ideal, evidently, was coke for constant use and gas for intermittent use; or gas for exclusive use where the labour-saving justified the extra expense, or where the user was willing to pay, as many users were, for the advantages to be obtained from what was the more expensive fuel for constant use if it was to be judged only by the cost hour by hour. He had in his hand the result of an investigation carried out by the Manchester Corporation on the question of gas and coal fires, which showed that although coal fires were cheaper in comparison with gas stoves in cases where rooms were used continuously and where burning went on all through the day, gas stoves were more economical, and—an important point—produced a more rapid rise of temperature, in cases where rooms were used intermittently. On those grounds, the use of gas stoves was desirable in committee rooms, which were used only occasionally or intermittently during the day. There were also in their favour greater cleanliness and a saving in labour attendant on their use. Accordingly the Manchester Corporation had decided to substitute gas fires for coal fires in the town hall in order to give a lead to smoke abatement in the city. In considering the question of the use of gas as against either coal or coke in the home, it was necessary to regard the domestic budget as a whole and not merely one fuel bill against another. That was an important point to be borne in mind.

MR. L. B. ATKINSON thought all must be gratified to feel that the author had disposed quite scientifically of the extravagant claims which had been made by the manufacturers of certain powders, supported by many great names of England, so far as families went. It only showed how little science such people adopted in their methods of conducting their own affairs, and perhaps some public affairs. The author had shown also some very interesting examples of how coke might be successfully burnt in a fire. The fact was, however, that although the discussion of fireplaces and fire grates had been going on for a very long period, it was extraordinary how the root of the whole matter was not reached. The fact was it had not yet been settled what was to be done with the coal fire. There had been discussions going on for the past few years, in which heating, medical, and physiological experts had taken part, as to whether what was required was to heat the air of a room or to heat the objects in a room. He thought everybody knew that on the whole it was more comfortable to have bodies in a room, both animate and inanimate, warmer than the air, than to have the air warmer than those bodies. For instance, the ordinary method of heating a house by radiators and pipes warmed the air first, and that, by conduction, warmed the objects in the room. The other way of heating was that which the author had referred to, and what his instrument showed—that the radiation passed through the air, hardly heating it at all, and warmed the other objects in the room. There was probably some balance between the two systems which was the most convenient. In his own home he had a hot-water central heating apparatus, by which he kept the air heated to about 55 degrees, and then for comfort he used fireplaces which were only lighted in the afternoon or evening. He believed that that was probably as satisfactory a system as could be devised with regard to the ratio of how much the air should be heated and how much the radiant heat should be relied upon for comfort. That was a point of view which required very careful consideration, and in which different forms of grates varied enormously. There were grates which would heat the air by passages behind them, and so on, and there were

other grates which would heat by radiation with very little warming of the air. As far as he knew, the only tests which had been published of the real efficiency of a grate were those to be seen in the *Lancet*, of May 19th, 1906. By "real efficiency" he meant the proportion of thermal units produced from so many pounds of coal which finally got into the room. That was the real efficiency of a grate. The tests were carried out, under the auspices of the Smoke Abatement Society in 1905, at the new block of Government buildings at the corner of Whitehall and Great George Street. Before fitting grates into the place the authorities set aside twenty rooms and invited manufacturers to test their various grates. At the conclusion of the general experiment, some tests were made of the actual efficiencies of the fires from the point of view of how many of the thermal units in the coal burnt finally came into the room, and the result—which he thought had never been contested—showed that of the total heat of the coal burnt that which was lost in the flue gases varied between 8·7 and 14 per cent. That meant that the percentage of the total heat of coal burnt which was given to the walls of the room chiefly by radiation amounted to about 86 per cent. It was clear, therefore, if those figures were correct, that there were forms of grates burning coal which were almost unsurpassed among technical apparatus of a common kind in the efficiency with which they converted the heat of coal into the purpose for which they were required, namely, getting it into the room. He thought few people realised that coal grates had reached that stage of efficiency. Over and over again he had gone into the question of gas coke as against coal, and he thought the gas companies did not sufficiently realise the damage they were doing themselves by not drying coke before they sold it. They often delivered large quantities of coke charged with water, and unless one had some means of pre-drying it the final result was not anything like equal to what ought to be obtained from the weight of carbon in the fuel.

Professor Wyndham R. Dunstan, C.M.G., F.R.S., thought the Society was indebted in more ways than one to the author for his paper. In the first place, the author had had the courage to do what a great many had not liked to carry out, namely, expose one of those very ingenious frauds which, from time to time, were perpetrated upon an uneducated public. He used the word "uneducated" advisedly, because in his view no one was properly educated who had not learnt something of the art of scientific observation. It was a matter of education, and such things were not likely to be altered unless we changed our system of education. He had been extremely interested in the ingenious instrument which the author called the "radio-thermometer," which might perhaps aid in solving some of the problems suggested by the last speaker. It was true that in warming a room by a fire, regard had to be paid to the radiant heat and also to the heat which was conveyed through the air, and he thought the author had devised a piece of apparatus which would enable a distinction to be made between those two forms of heat, and possibly would enable an estimate to be taken of the relation between the two. It appeared to him (the speaker) that the real solution of the smoke question was the use of gas. He believed in the end people would be converted to the use of gas fires, especially those worked upon the so-called incandescent principle. There was one point which he desired to commend to the notice of the Chairman and other representatives of the gas industry, and that was the price of gas, which appeared to him really to govern the whole situation. If cheap gas could be obtained smokeless fires would result, but so long as the price of gas was as high as it was, it was a bar to the extensive use of gas fires.

Dr. T. M. Legge said there were two points which had struck him in the paper: one, as to the success a fireplace would have in attracting the public taste or not. The suggestion he would make was that the author should enlist the interest and artistic ability of tile-makers. It was the tiles round the fire which made it beautiful, and not the fire itself; and so long as there were highly-glazed, smooth, and polished tiles there would be no beauty in the grate. The tiles must have rough surfaces and break up the light, not reflect it. The other point was the appalling price one had to pay for gas fires.

Mr. John Slater, F.R.I.B.A., said in his opinion the great efficiency of modern grates had been brought about by diminishing the depth of them. The old grates used to have a considerable depth from the front of the bars to the back of the grate, which did not occur in the new types. With regard to the cost of gas fires, recently he installed in his flat a number of gas stoves and a water heater. He had been told by the gas company that the water heater, if furnished with a thermostat, would enable him to get hot water all day long at a very small expenditure of gas. At the end of the first quarter he found he had used, on one of the floors only, 84,000 cubic ft. of gas. That was for the water-heater, a couple of bedroom stoves, and a small gas stove used for making toast. The gas company thought it rather excessive, and made a test, and it was found out he was using 860 cubic ft. of gas per day. The result was that he told the company to take their installation out and put something else in its place or he would go back to ordinary stoves. He happened to have a small cottage in the country, and the local gas company supplied him with gas for heating purposes at a very much lower rate than gas for lighting purposes. Could not the town gas companies instal a separate meter for heating purposes

in the same way? He thought if they could, many people would instal more gas stoves into their houses than they at present had.

Lieutenant-Colonel Allan Cunningham inquired what became of the ash in the author's type of grate. Surely there was a great accumulation of ash?

Mr. T. Potterton gave detailed figures in regard to a test which he had carried out in his house to ascertain the running cost of heating by coke, which showed that such cost amounted to a little over a farthing per hour.

Mr. H. Hartley said there was one point with regard to the author's type of grate which he should like to raise, and that was with reference to the ventilation. Unfortunately, one was dependent upon the entrance which was provided to the fireplace and the entrance to the chimney for ventilation of the room, and, if he understood the author, the suggestion was that the whole of such space should be filled up with coke, which would not entirely stop the passage of air up the chimney but which would probably interfere materially with the amount of air which passed through the room and up the chimney. Had the author conducted any tests to determine the effect on the ventilation of the adoption of the type of coke fire suggested in the paper? Mr. Harcourt would be interested to learn that an account of a radiometer, which the radio-thermometer resembled in some respects, had recently been published in the *Journal of Gas Lighting*. This instrument had been designed for use in connection with the testing of gas fires, and consisted of a block of metal, such as copper, which was suspended in an enclosure maintained at a steady temperature by a stream of water. This instrument enabled a high degree of accuracy to be obtained in the estimations of the radiant heat of gas fires.

Mr. A. H. Barker said Mr. Atkinson had quoted certain tests made ten years ago in regard to the efficiency of an open fire, and had stated that those tests had not been challenged. He (the speaker) thought a sufficient challenge of the accuracy of them was the careful study of them. He had read the tests when first published, and had then thought he had never seen such an absurd exhibition of incompetence as was displayed by them. The figure of 86 per cent. might be taken as worthless. No such efficiency had ever been obtained out of a coal fire. The tests had been carried out in the following manner. A certain weight of coal was weighed into a certain grate, and the combustion started, and measurements taken of the velocity of the gases up the chimney by some such absurd method as the exploding of some powder. The velocity was something like 3 ft. 6 in. or 4 ft. in a chimney 50 ft. high with a temperature of 120. The efficiency was taken in the following manner: The experimenters said, "We can only find that 14 per cent. is lost in the air. The difference, which we will not observe at all, and which is 86 per cent., must be transmitted into the room by radiation and so forth, and therefore the efficiency of the fire is 86 per cent." That was to say, the crucial point of the whole experiment, the tail-end, which was not observed at all, was quoted as the amount of heat usefully employed. Any experiments made on those bases condemned themselves.

The Chairman said Mr. Atkinson had raised the point of gas companies drying coke before they supplied it. He was afraid, if Mr. Atkinson wanted his coke dried by the gas companies before delivery he must be prepared to pay a considerably bigger price, because the labour involved would be considerable. The percentage of water in coke was not by any means a heavy one; it was only the water which was required for quenching the coke as it came from the retorts. As to the price of gas for heating purposes, gas undertakings could not, in justice to their consumers of gas for light, charge a different price for gas used for heating, because there was no appreciable advantage to a gas undertaking in regard to whether the gas they supplied was used in the daytime or was used in the evening. In the case of an electrical undertaking, where the demand had to be manufactured as it occurred, there was a great deal of advantage in getting a day load to occupy the idle plant. In the case of a gas undertaking, which was able to manufacture twenty-four hours a day, putting gas into the gasholder during the time of lightest demand, and drawing upon the gasholders during the time of maximum demand, no appreciable advantage could accrue from a levelling down of the load factor. The only advantage would be the reduction in the capital cost for storage, which would not justify any differentiation of price. It should be borne in mind that the price of gas throughout the country had steadily diminished in recent years. Another factor which had cheapened the use of gas for heating was the far greater efficiency of the modern gas fires as compared with the gas fire of a few years ago, in that very much more heat, especially radiant heat, was obtained for the gas consumed than was the case five or ten years ago.

The Author, in reply, said he was glad to hear that one need not accept as very authoritative the figures which had been given on the proportion of radiant heat to total heat which was produced by fuel. He thought the figures had been quite incredible. With regard to the question of ash, the ash settled itself. He had no doubt it did retard the rate of combustion, and in that respect there was powder which was naturally produced, and which had the effect for which another powder had been credited! As to water in coke, he had never suffered from coke retaining an undue quantity

of water. Some coke was exceedingly greedy of water. If coke was put in soak through the night it was surprising how good its appetite for water was. From that fact he gathered there was not much water in the coke when it was delivered.

A vote of thanks was accorded to the author for his interesting and valuable paper.

UTILISING COTTON STALKS.

At Greenwood, Miss. (U.S.A.), a pulp mill with a capacity of 50 tons daily is being erected to manufacture pulp for paper-making from cotton stalks, a hitherto unused by-product of the cotton fields.

This industry is of vast economic value to the cotton-growing sections of America, as well as of great value to the paper-making trades at this time of increasing scarcity in pulp-making materials the world over.

The cotton plant is a well-known annual plant, the stalks of which, after producing its crop of cotton, have been destroyed by the farmer in preparing his ground for the succeeding crop. A conservative estimate of the annual supply of cotton stalks in the cotton-growing sections of the United States is about 75,000,000 tons. If but 25 per cent. of this can be utilised it will aggregate an approximate production of 6,000,000 tons of paper annually, worth more than £10 per ton. As there appears to be an inexhaustible supply of cotton stalks that are useless for any other purpose, it ensures a "raw material cost" of little variation from year to year. Usually about 10,000 cotton plants are grown on an acre of ground. In the Yazoo Delta section the growth of the cotton plant is large, often attaining a height of 8 ft., 10 ft. and 12 ft., the stalks of which in a dry condition weigh from ¾ lb. to 3 lb. each.

The best cellulose for durable papers will be obtained from the fibres of the cotton plant. This particular fibre is a thin-walled tube which collapses in a peculiar twisted manner in the beating process, interlaces in the felting process much better than any other fibre and holds its grasp tenaciously. It is strong, flexible and durable, of light weight, and with double the tensile strength of stock used in ordinary wrapping paper.

Paper made from cotton-plant fibre, when nitrated, becomes an efficient and convenient form of smokeless powder.

Chemical works will also be erected at Greenwood in which to conserve and refine the by-products produced which will be of much value in arts and manufactures.

Large quantities of old cotton stalks are being delivered at the mill site, the cost delivered being about 12*s*. 6*d*., or $3 U.S. currency, per ton. The daily consumption of stalks will be 150 short tons, which will produce 50 tons of valuable pulp.

The mill located on the Southern Railway at Greenwood, Miss., is the first commercial pulp-mill of its kind ever erected, and the industry has promises of surpassing the present importance of the cotton oil industry in America.

The process and details for manufacturing pulp and paper from cotton stalks were worked out and the value of the product demonstrated in an experimental plant at Philadelphia, Penn., with the result that it was decided to construct a commercial and permanent plant at Greenwood, Miss., U.S.A.

WILLIAM C. OLDS.

INDIAN RAILWAY EARNINGS.

Up to the week ending February 6th the total decrease of railway earnings as compared with the previous year was 2·94 crores of rupees, or a decrease of 5½ per cent. A detailed statement in the *Gazette of India* gives figures for each railway, which are of considerable interest.

Six railways show decreases of over 10 lakhs of rupees, the list being headed by the G. I. P., which shows a loss of 75 lakhs, largely owing to the cessation of cotton exports and the general disappearance of the export and import trade of Bombay during the early months of the war. Next comes the Eastern Bengal State Railway, with a loss of 46 lakhs, due to the decrease of jute exports. The third is the North-Western Railway, with a loss of 37 lakhs, due to the shortage of wheat exports and war disorganisation. The Oudh and Rohilkand Railway, for similar reasons, is fourth on the list, with a decrease of 31 lakhs, while the B. B. and C. I. (standard gauge) is fifth, with a decrease of 17 lakhs, and the Bengal-Nagpur Railway is sixth, with a decrease of 12 lakhs.

Six railways show decreases between 5 lakhs and 10 lakhs—namely, the East Indian Railway (9½ lakhs), the B. B. and C. I. metre gauge (8¾ lakhs), the Burma Railways (6⅝ lakhs), the Jodhpur-Bikaner (6⅜ lakhs), H.H. the Nizam's (6¼ lakhs), and the South Indian (6 lakhs).

Fifteen railways show losses between 1 lakh and 5 lakhs.

Among the lines showing increases several are those which have only recently been opened. The largest increase is from the Delhi-Agra Chord of the G. I. P., which shows an increase of 75,000 rupees. Four lines show just over 1 lakh increase each.

The list of the gross losses, however, is not a good guide to the severity with which the decreases are felt by individual railways. A loss of 9½ lakhs on 9 crores earnings, as in the case of the East Indian Railway, is not felt so much as a loss of 4 lakhs on 14 lakhs earnings as in the Bhopal-Itarsi line. To gauge the position, therefore, from the railway point of view, it is necessary to group the lines according to percentage losses of gross

earnings in 1914. Arranged thus, the principal railways show the following results :—

Decreases (percentage)—Bhopal-Itarsi (G. I. P.), 27; Burma Extensions, 22; Oudh and Rohilkhand, 15; Eastern Bengal State Railway, 14⅜; Jodhpur-Bikaner, 14; Nizam's, 12; G. I. P. (main line), 10⅝; B. B. and C. I. (standard gauge), 5½; North-Western Railway, 5; Tirhoot, 5; Darjeeling-Himalayan, 4½; Burma, nearly 4; Bengal-Nagpur Railway, 3½; South Indian, 2½; Assam-Bengal, 2; Madras and Southern Mahratta, 1·2; and East Indian Railway, 1.

Increases (percentage) — Jullundur - Doab, 66; Agra-Delhi Chord (G. I. P.), 3; and the Delhi Umballa-Kalka, 2½.

Put this way, it will be seen that the G. I. P. falls from the first to the seventh place, while the East Indian Railway drops from the seventh to the seventeenth, its 9½ lakhs representing only 1 per cent. on the gross earnings.

So far as the revenues of India are concerned, however, it is the gross totals that matter. They show a loss up to February 6th of 264,00,000 rupees on State and guaranteed lines, and 29½ lakhs on all other lines.

AGRICULTURAL CO-OPERATION IN SOUTH AUSTRALIA.

In the early days of Australian colonisation, when the settlers, measuring the new country by English standards, took up individual holdings of some 80 acres in extent, a primitive form of co-operation may be said to have existed. Few of the farmers possessed all the implements necessary for working a farm successfully: each borrowed from his neighbours what he lacked himself; so that, in a sense, the first settlers were co-operators.

But that stage of cultivation has passed away. Farms at the present day consist of any number of acres from 1,000 to 5,000, and are stocked with the most modern machinery and other aids to cultivation, so that each forms an independent producing unit. Co-operation among farmers under these conditions must naturally be something quite different from the primitive co-operation of the pioneer settlers; and in fact such agricultural co-operation as now exists in Australia is chiefly represented by a few large societies for purchase and sale which number their members by thousands, own a large amount of valuable property in the form of warehouses, machinery and farm supplies, and transact business upon a huge scale.

The work of the two principal agricultural co-operative societies in South Australia is dealt with in an article in the January number of the *Monthly Bulletin of Economic and Social Intelligence*, published by the International Institute of Agriculture. The two societies are the South Australian Farmers' Co-operative Union and the Eudunda Farmers' Co-operative Union, and the article in question is contributed by Mr. T. E. Yelland, Secretary of the South Australian Union.

The South Australian Union, founded twenty-five years ago, has now some 6,000 members, owns offices and machinery stores in Adelaide and warehouses for wheat, skins and wool in various parts of the State, conducts a large banking business, and even publishes a monthly newspaper for the information of its members. The society sells wheat, oats, barley, hay, wool, skin, hides and livestock on behalf of its members, and supplies them with corn-sacks, hardware, manures, farm implements and machinery, including engines. Though registered as a limited company, the society is conducted strictly upon co-operative lines, all profits, after providing adequately for a reserve fund, being distributed among the members, and membership being open to all farmers without exception. About 70,000 shares have been allotted. The minimum number that may be held is ten, and the maximum actually held by any one member at present is about two hundred and fifty. The voting power is so distributed that any two members holding twenty shares each can outvote the largest holder of shares in the society. Shares are transferable under certain conditions.

The management of the society is vested in seven directors elected by the shareholders, and the business is divided into departments with a manager in charge of each.

The other society described by Mr. Yelland was founded at Eudunda in South Australia about eighteen years ago. A number of the farmers of Eudunda who sold the wood from their property as fuel, dissatisfied with the prices obtained in the towns, appointed their own agent in the city market. The agent was charged with the sale of the wood and the purchase of household supplies for the farmers. This arrangement proved very satisfactory, and little by little the transactions of the society were extended to other farm products. The society opened stores at convenient points on the railway. At the present time there are fifteen of these stores, and the company has placed a trading steamer on the River Murray and is thus able to cover a very large district. There are more than 2,500 members; the share capital amounts to £31,000; and the reserve fund to £3,360. As a rule the society pays a bonus of 5 per cent. on purchases and the same rate on capital.

Co-operation has also been applied to two other branches of agriculture in South Australia, namely, dairy farming and fruit-growing. A number of co-operative butter and cheese factories have been established by dairy-farmers in the south-eastern part of the State about three hundred miles from Adelaide in a good grazing district, and the results obtained have been very satisfactory. Nearer to Adelaide co-operative dairies have been started, but have not proved a success, and the producers who formerly supplied the milk to the co-operative concerns now separate the cream with a hand "separator" and send it to private butter factories in the towns.

Co-operation among fruit-growers is of recent

introduction, but gives promise of being very successful.

Naturally co-operators in Australia are beginning to feel the need of a central federation of co-operative societies. The co-operative spirit is growing; the farmers as a body are becoming interested in the movement; and it will probably not be long before the existing societies combine for the development of their business and the protection of their common interests.

ARTS AND CRAFTS.

Nature Study and Art.—The spring show at the Whitechapel Art Gallery is generally of interest to lovers of arts and crafts, and this year the committee had the happy inspiration of holding an exhibition of nature study and art The exhibits were distributed over four sections, the second of which was devoted to design and craftwork, and was planned to show "the different treatment necessary when . . . natural forms are used for decorative purposes." To say that the collection might with advantage have been enlarged in some directions and curtailed in others is, perhaps, only to admit that it shares the characteristics of all exhibitions. Certainly the promoters of this particular one set themselves a very difficult task, and one very well worth the doing. If only an exhibition of the same kind could be organised on a larger scale and in a more central position, with expert demonstrators in attendance to show students why some treatments of natural form are good and some bad, and why certain conventions obtain in designs for particular processes it might do much to awaken in the rising generation that sense of design for which the desire to capture German trade ought to provide a demand. With a competent guide to point out the knowledge and dexterity demanded by such apparently simple work, Mr. C. F. A. Voysey's designs for textiles, embroidery and wallpapers might prove very stimulating; at Whitechapel one could not but feel that they would probably lead unwary students astray. That kind of work looks, and is, so simple when you are an accomplished draughtsman, but the beginner would be well advised to leave it alone. Mr. Walter Crane's wallpaper designs, on the other hand, give no illusion of simplicity. It quite evidently took a master to design them, but they are beautiful examples of elaborate pattern design. Perhaps the most practically useful exhibits were those sent by Mr. Christopher Whall, including studies of swallows and plants, together with the use to which they have been put in decorating a roof, and also drawings of foliage and the decorative rendering of them in cartoons for stained glass. It is just at this point that so many would-be designers fail. They can make a study, but when it is made they often do not know how to use it; or they can scheme the lines of a design and fall short when it comes to clothing the skeleton with foliage which is at once conventional and not unnatural. Mr. Lindsey P. Butterfield's copies of old ornamental floral and foliated forms were of a kind admirably suited to guide the student aright, and to remind him of the necessity for studying not only nature herself but also other people's interpretations of her. One would have liked, however, to see a larger series of plant sketches more or less on the lines of the few excellent examples by Miss J. Foord to show how plant-form studies should be made with a view to their use as bases for designs. Many learners and teachers, too, fail to realise that to make a drawing of a plant is not necessarily to provide oneself with useful material for a repeating pattern or even for a design to fill a space. A useful object-lesson in the difference of effect between a design for chintz and the same pattern printed on the actual fabric was furnished by the series of Morris designs accompanied by the reproductions from them, but it is to be regretted that the authorities did not always find it possible to hang the original and the copy side by side with the pattern running in the same direction.

The committee of the Whitechapel Art Gallery have achieved a very useful piece of work in initiating an exhibition of this kind, but there is room for more to be done in the same direction. The improvement of our design is a much more important matter than many people will allow, and one which is of the greatest moment to some of our large manufacturing interests. British craftsmen at last seem to have awakened to this fact. It is to be hoped that they will set to work in practical fashion not only to draw artists and manufacturers together, but to improve the training of the designer.

Jewellery.—It is now many years since the making, by men and women craftworkers, of a different kind of jewellery from that ordinarily shown in the shops came into vogue. The English movement was itself an outcome of the popularisation in this country of French work of more or less the same type; but whilst the French artistic jewellery was as a rule the output of craftsmen trained in the workshop who happened to have, over and above their manual dexterity, real artistic taste, the earlier British work, on the other hand, was produced by men, artists by training, who later on in their career turned their attention to craftwork. The result was that a good deal of the handmade jewellery of this period, though admirable in conception, was somewhat lacking in technical accomplishment. Jewellery making became after a time a popular craft, one might almost say a fashionable hobby, for the amateur, and art students—especially women art students—took it up in

the hope of making money by it when they were but poorly equipped for their task. Indeed, from the point of view of the man in the street, little versed in matters artistic, the momentary flutter might almost be said to have died out, leaving behind it as its contribution to the arts and crafts movement of the day a type of machine-made jewellery sold in a few shops planned rather on the lines of the handmade articles, and a small demand for inexpensive craft jewellery met mostly by women craftworkers turning out their wares at a price which does not suggest that jewellery making is a craft at which a living wage can be earned. That is not, however, the whole of the story by a very long way. The fashion has indeed passed, but it has left behind it a good deal more than that. It has influenced considerably the style of the less expensive jewellery commonly worn, so that the characteristic ornaments of many lands find a readier market over here than they used to do. Not only Swiss and Italian work is to be seen in the London shops to-day, but Russian peasant work and Scandinavian filagree and enamel, as well as Indian, Japanese, and Chinese jewellery. Further, though its influence on British trade-work has not, on the whole, been very great, we have to-day a body of craftworkers (women for the most part) who are doing thoroughly good work of a very modest type, and a few whose productions are worthy to be compared with the best examples of old work and of modern foreign workmanship. Of recent jewellery of the simpler kind, the specimens shown at the little exhibition of the '91 Art Club, held at the Alpine Club, were very good examples. Several lady jewellers exhibited their handiwork, all of which reached a satisfactory standard of design and workmanship. The case of objects shown by Miss Ethel Rickert contained some pretty little brooches and pendants, whilst the exhibits of the Misses Frances and Violet Ramsay had a distinctive character of their own which marked them out from the ordinary work of the kind. Their pendant of gold and silver set with lapis-lazuli and blister pearls, unusual and rather oriental in form, was a particularly well-thought-out piece of work. Amongst jewellery of a more ambitious kind, the necklace in gold and precious stones and the Golden Fleece pendant designed by Mr. Edward Spencer for the Artificers' Guild, and carried out by Messrs. W. Glennie and Charles Moxey, is deserving of notice. The galley, her sails well filled with wind, rides gallantly on a sea of blue opals studded with rocks of uncut sapphire. The treatment of the boat and its surroundings is highly decorative, and the workmanship is worthy of the design. The arts and crafts movement may not have done for jewellery all that it was hoped it might accomplish, but it has given rise to a type of work, by no means to be despised, which has certainly come to stay.

Spring Colour-schemes.—Colour schemes this spring are still on the sombre side. The daring hues of the Austrian prints exhibited at Goldsmiths' Hall find very little echo in the London shops. There are a few gorgeously-coloured French dress silks about, and some brilliant Chinese embroideries, but the British furnishing fabrics are no more cheerful in colour than they were last autumn. This may be partly due to difficulties in obtaining dyestuffs, but a certain quantity of these is coming in from Switzerland, and it looks rather as though people had become so accustomed to khaki that pure bright tints do not for the moment attract them. What little vivid colour there is about is practically confined to cretonnes, and is almost always on a black ground, so that, brilliant as some of it is in itself, the effect of the material as a whole is not really gay. For the most part, the colours on the black backgrounds are deep rich purples and greens, which even on a white ground would look rather sober. The prevalence of shadow-printed materials, further, makes for a lowness of key in cretonnes and linens of a rather different kind. Carpets reflect the prevailing taste of the moment, the plain ones are often black or buff, and those which are patterned are, very often rather subdued in tone. Tapestries and damasks, again, are mainly on the dull side.

CORRESPONDENCE.

MOTION OF LIQUIDS.

Whilst thanking Professor F. C. Lea for his review of my little book on "Motion of Liquids," there are one or two small misconceptions in it which I should like to remove.

He says I make "an attempt to show that when a body is at rest in a flowing stream, the pressures behind are not the same as when the same body is moving at the same velocity in a liquid at rest"; it should be "in front of," and not "behind." This is, of course, what is called in France *le paradoxe de Dubuat.*

Again, it is hardly fair on me to say that I separate "impact with shock" from "static liquid." Remembering Sir W. Herschel's caution* that "some, nay most, [words] have two or three meanings; sufficiently distinct from each other to make a proposition true in one sense and false in another. . . . It is, in fact, in this double or incomplete sense of words that we must look for the origin of a very large portion of the errors into which we fall"—remembering this, I found authors ordinarily employing the word "impact" in a very loose manner, and to avoid doing the same myself, I used the word in two senses, which I defined as "impact with shock" and "impact without shock." Similarly I differentiated between "static liquids" and "non-static liquids." This

* Discourse on "The Study of Natural Philosophy."

is, in fact, the leading idea, or dominant note, of the whole book.

Since the meaning of "static" is not generally understood, I will give an example in explanation. The water in the Marylebone swimming-bath is a "static liquid." It cannot be said to be "at rest," since we know that it is moving at a velocity of 50,000 or 60,000 miles per hour. It is, however, not changing its shape—there is no relative motion between any of its parts—it is moving like a solid.

A few miles away is the River Thames, the water of which is moving a very few miles faster or slower than the water in the bath; the difference would be only measured by some hnudredths of one per cent. It is a "non-static liquid," for the different parts are constantly changing their relative positions. Propositions which are true for the water in the bath are not necessarily true for the water in the Thames.

Certainly I follow the teaching of "Newton, Dubuat and others"; the expression "and others" is, however, hardly an appropriate one to apply to such names as Sir George Stokes and Lord Kelvin. I should prefer to say that I follow the teaching of "Lord Kelvin and others." A very cursory study of Thomson and Tait will show that Lord Kelvin believed in the parabolic formula expressing resistance and not in the logarithmic one.

The small sting in the review (if there is one) is to be found in the tail, where I am accused of neglecting "the enormous mass of data gathered during recent years."

It is quite true that I must plead ignorance of Mr. Lees' work on the flow of liquids in pipes, but, *per contra*, I refer to even later work on this subject by an author who will, probably, carry more weight than even Mr. Lees—Dr. Stanton, of the National Physical Laboratory. He has shown, experimentally, that the resistance may be expressed as

$$R = A\mu\,(Vl) + \rho B\,(Vl)^2,$$

where the power of V involved in the first term is certainly unity.

I regret not being aware of the "enormous mass of data gathered during recent years" on the resistance of liquids, though I know of a good deal on air resistance. Finzi and Soldati have done some work on water; Riabouchinsky has started a hydrodynamical laboratory, but has published nothing yet. I know of no systematic work later than Bazin.

R. de Villamil.

THE UTILISATION OF SOLAR ENERGY.

As your reporter did not catch the name of the inventor of the steam-ether compound-engine, perhaps you will allow me to state again that he (du Trembly) and Dr. Latiere, of La Seyne, concluded rightly or wrongly that it was more economical to use the sun for growing fuel than for raising steam; and this was so firmly impressed upon my youthful mind in 1856 (five years before Mouchot's patent) that it sticks there still! To compare efficiencies *per acre* is misleading; for, where land is available and labour cheap, it is possible to burn, in boilers occupying less than one-tenth of an acre, the fuel gathered over a thousand acres, and thus to save the enormous expense of a few acres of reflectors.

Monsieur C. Tellier made a name and some money for himself in connection with the "Frigorifique," as he was the first man to bring chilled meat from South America; and, in 1879, one of his refrigerators was taken out of the "Frigorifique" by me and set up experimentally for Mr. D. Tallerman in the arches under Cannon Street Station; but, some ten years later, I found that Tellier was beginning to dabble in solar-energy schemes—and he has since died a pauper!

When we have used up all our coal and oil, all our timber and other vegetation, we can turn our attention to improving the type of apparatus about which Mr. Ackermann has given us such a valuable paper. It is possible to increase the efficiency of the Shuman plant by first raising the temperature of the water considerably without using reflectors, reserving the latter only for turning hot water into steam; but, even so, the solar-energy machine cannot compete economically against other means at present in vogue.

W. H. Massey.

9, Queen Anne's Gate,
Westminster, S.W.

At the meeting last night, when Mr. Ackermann read a paper on "The Utilisation of Solar Energy," I was reminded, by the mention of Mr. W. Adams, that in 1877 or 1878 I was, in a small way, a collaborator with that gentleman in some of his experiments. He came over to Calcutta to see if his work could be brought into more extensive practical use, and called upon me with a Colonel Money, who was largely interested in tea-growing and preparation, to discuss the question of the application of direct solar heat to the several processes of tea preparation, raising steam, drying tea, etc. I recommended that a practical experiment should be made at once to test the capability of his plan to get up and maintain steam in a small boiler. I selected one of 6 h.p. capacity, made of thin steel sheets, suited to external firing, and placed it in the focus of a large curved reflector composed of ordinary silvered glass panes 9 ins. by 6 ins., in portable wooden frames. I do not remember the dimensions of the reflector or the focal length, but they were fixed at what Mr. Adams considered, from his experience, to be sufficient for, and best suited to, the purpose.

The sun's rays were impinged by reflection on a suitable area of the boiler shell for the whole of a bright day in February, but the heat rendered available was not sufficient to raise the water in the boiler to 212° F. Two or three trials were made, with such alterations as suggested themselves, but without any success, and the experiments were given up.

I did not make these remarks in the discussion as there were many speakers, but it occurs to me that they may be of some interest.

South Villa, The Vale, Hampstead, N.W. G. E. JONES.

With regard to Mr. A. S. E. Ackermann's very interesting paper on Solar Energy, which he read before the Society last week, I wish to say that, appreciating the fact that the present installations are evidently only in their infancy, I cannot help thinking that some form of sun-power energy must have been employed in the time of the Pharaohs. Those vast Pyramids, and the Sphinx itself, must, to my mind, have been hoisted by more than actual manual labour. I think, therefore, that there is a great future for sun-power plants when more fully developed.

D. R. BROADBENT.

NOTES ON BOOKS.

A HISTORY OF THE ROYAL DUBLIN SOCIETY. By Henry F. Berry. London: Longmans, Green & Co. 1915.

The "History of the Royal Society of Arts," published two years ago, has now been followed by a companion volume recording the history of the sister, and rather older, institution of Ireland. The publishers have paid us the compliment of closely imitating our *format*, for the two volumes, in size, printing, binding and general appearance, are so similar that they might be taken for two volumes of the same work. And as the two books resemble one another externally, so also their internal contents deal with objects almost identical.

It may be hoped that our own history helped to provide some information about the arts and industries of England during the latter half of the eighteenth century and the first half of the nineteenth, and it is pleasant to be able to testify that the kindred volume is full of most valuable information about Irish progress in science and art during the same, or indeed during a rather longer period. Personal considerations, which necessitated the curtailment of the English record, have fortunately been absent in the case of the Irish one. Dr. Berry, whose well-known familiarity with Irish historical questions renders him admirably qualified for his task, is not, so far as the present writer is aware, officially connected with the Royal Dublin Society, so that there can have existed no feeling of responsibility for the work of recent years to prevent his carrying on his record to the present date.

Amongst the very earliest records of the Society of Arts there is still preserved a MS. account of the origin and progress of the Dublin Society, "for the encouragement of Husbandry and kindred objects," which was read, at a meeting held on June 16th, 1756, by Philip Carteret Webb, the well-known antiquary and lawyer, who took a leading part in the prosecution of John Wilkes seven years afterwards. The communication was sent by Mr. William Henry, of Kildare Street, to Dr. Stephen Hales, for the Society.

There need be no reason to doubt that the organisers of the London Society profited by the experience of those who were carrying out precisely similar work on the other side of St. George's Channel. It is certain that the two Societies were in frequent communication, and worked harmoniously together. The lists of "premiums" offered were exchanged and ideas or suggestions were reciprocally adopted. A pleasant proof of the friendly relations existing is afforded by the fact that the President and Secretary of the Society of Arts (for the time being) have for long been honorary members of the Royal Dublin Society.

One great difference there is between the two Institutions. The Irish one from a very early date has been liberally subsidised by the State. The English one has never received a penny of Government money. On two occasions, in connection with the formation of the 1851 Exhibition and with the foundation of the South Kensington Museum, it was repaid a portion of the funds it had expended, but on those occasions it was exceptionally fortunate. The treatment of the Irish Society was very different. In 1746, when the Society was not yet fifteen years old, the Earl of Chesterfield, when Lord-Lieutenant of Ireland, recommended that a grant should be made to them of £500 a year, and this was at once done. Some other gifts of public money are referred to, and in 1761 it commenced to receive regular Parliamentary grants (from the Irish Parliament). In that year a sum of £12,000 was voted to it. The precise amount allotted appears to have varied from year to year, but "in the year 1800, the last of the Irish Parliament, the Society's grant amounted to £15,000." After the Union £10,000 for twenty years was granted. This was afterwards reduced to £7,000, and (in 1831) to £5,500. This considerable income, supplemented by the contributions of members of the Society, was for the most part expended precisely in the same way as the funds of the London Society of Arts, in premiums for the encouragement of Agriculture, Industry and Fine Arts, and there can be on doubt at all that in both cases the money was usefully and beneficially employed.

That in the early days the administration was a little lavish is the only piece of criticism which may fairly be offered. For this an ample excuse is provided by the ready supply of Government money placed at the disposal of the administration. Our own predecessors deserve no credit for the fact that a strict economy was forced

upon them by the need for collecting their revenues from the public before they spent them.

When the time came for the abandonment of the eighteenth-century notion of encouraging industrial development by small prizes; when it was found that industrial development itself provided rewards far larger than could be supplied by societies and committees, however benevolent and well-intentioned, the Dublin Society was fortunate in possessing the funds and the State support which enabled it to devote its energies to purposes better suited for modern needs.

It must certainly be the fact that no other Institution in the three kingdoms has received anything like the same amount of State assistance, and it is also a fact that the Society has made excellent use of the funds with which it has been provided.

Its constitution has been on several occasions very considerably modified. Its first charter was obtained in 1750, and its principal objects then were the encouragement of Husbandry, Manufactures and Art. In 1866 it obtained a supplemental charter, and in 1888 a second supplemental charter. On both occasions great alterations were made in its constitution to correspond with the changes which the course of time had necessitated in its objects.

Its Drawing School, started in 1751, rendered valuable service by educating Irish artists until it was transferred to the Science and Art Department in 1878. Its Agricultural Research Laboratory and its Geological Museum, both established at the very beginning of the nineteenth century, each in its own province did invaluable work until they also were taken over by the Science and Art Department in the year above mentioned. Its Botanic Garden, founded in 1737, and in later years largely subsidised by the Government, deservedly attained a very wide reputation until its control also was taken over by the Department in 1878.

Its Library, which dates back to 1731, was in 1877 converted into the National Library of Ireland, under the Science and Art Department. The National Library still occupies a part of Leinster House, where the Society established itself in 1815.

About 1800 it dropped its agricultural work on the foundation of the Royal Agricultural Society of Ireland. But when that Society came to an end in 1830 the Royal Dublin Society renewed its agricultural labours, though they took a new form, and led to the establishment of the two celebrated shows of live-stock and of horses, which probably are the most popular undertakings the Society ever undertook—indeed, its Horse Show is probably more widely known than any of the Society's more strictly scientific work.

It also had its part in the origination of International Exhibitions, and the exhibitions of Manufactures started in 1835 culminated in the fine Industrial Exhibition of 1853.

Of late years, since its last Charter of 1888, the Society has confined itself more strictly to pure science work on the same lines as the Royal Society of London, and to the promotion of Agriculture, principally by the two shows above referred to.

The long history, which is given in full detail by Dr. Berry, should be studied with interest by the Fellows of the kindred Society, which during practically the same period of time has been carrying on work, often identical, and always closely allied, with that of the chief scientific institution of the sister kingdom. Both Societies alike, the Irish and the English, can look back on a long history of valuable work efficiently carried out; both alike have had their successes and their failures. But, on the whole, no fair-minded student of the history of both Institutions can fail to recognise the value of the labours of both of them. In both cases alike, their objects and their efforts have changed with the changing years, and both alike may confidently still look forward to a prosperous career, if in the future, as in the past, they show themselves capable of adaptation to the constantly altering conditions of Science, Art and Industry.

WOOLLEN AND WORSTED. By Roberts Beaumont, M.Sc., M.I.Mech.E. London: G. Bell & Sons, Ltd. 30*s*. net.

Professor Beaumont's "Wool Manufacture" has long been recognised as a standard text-book on the subject. When the third edition was exhausted, he was asked to prepare a thoroughly revised fourth issue. The result of this request is the present volume, which, however, must be regarded more as a new work than a mere revision. It deals with all the processes connected with the production of woollen, worsted, and union textiles, and complete new sections have been added on wool scouring and drying, carding, condensing, combing, drawing and spinning machinery and operations; the French system of worsted yarn construction; the principles of design applicable to the several grades and classes of woollen textures made of wool and other fibrous substances; and recent developments in the art of manufacturing.

A great deal of original research into the various qualities of wools and other fibres has been conducted by Professor Beaumont, and the results of this are embodied in the book. There are also full and valuable descriptions of the different types of mechanism, illustrated by sectional drawings.

A word of praise must be given to the publishers, Messrs. G. Bell & Sons, Ltd., who have produced the book in a manner entirely

worthy of a standard work. It is printed in large clear type, and contains 469 illustrations in the text in addition to 42 plates. The blocks are so excellent that they could hardly be improved.

GENERAL NOTES.

New Zealand Fisheries.—Mr. W. G. Wickham, H.M. Trade Commissioner for the Dominion of New Zealand, has been making a tour of the east coast of the Southern Island. The most important fishing centre in New Zealand is the Bluff, and he comments on the possibility of erecting fish-manure works here. Many farmers in Southland, he says, know the value of fish manure, and the local freezing works at Ocean Beach, which now treat meat offal, could also deal with fish. The fishing is of two kinds. There are the deep-sea oyster-beds round Stewart Island, from which supplies are drawn for New Zealand and for shipment to Tasmania and Melbourne; and the ordinary deep-sea trawling and netting. A few of the boats engaged in the latter branch are fitted with refrigerators, and are thus enabled to stay at sea for several weeks The fleet numbers at least one hundred craft, ranging from fairly large steam-trawlers down to large launches and sailing-boats. The launches and sailing-boats are all fitted with auxiliary oil engines.

Production of Potash from Kelp in the United States.—H.M. Consul-General in New York (Sir C. W. Bennett, C.I.E.) has forwarded an extract from the local press, in which it is stated that 10,000 tons of American potash manufactured from kelp were recently sold in New York at a price comparing favourably with that commanded by the German product in normal times. The source of this potash is what is known as "giant-bladder" kelp, which, when dried, contains over 20 per cent. of potash, as well as other substances valuable to fertiliser consumers. The kelp is gathered by a submarine harvester, with a cutting device mounted between two pontoons. This harvester cuts through the kelp groves a swathe about 16 ft. wide and from 2 to 10 ft. below the surface of the water; by cutting 5 ft. below the surface it is found that 85 per cent. of the total weight of kelp is harvested. The kelp, when cut, is automatically gathered from the water and chopped into 6 in. lengths. The harvester with scows attached has a capacity of 50 tons per hour, from which 5 tons of dried kelp are obtained.

Australian Molybdenum. — Molybdenum, which is practically indispensable for the production of certain grades of steel, has in the past been supplied to this country almost exclusively by Germany. The ores occur over a wide area in Australia, and also in Norway and Peru. Arrangements have recently been concluded, according to the *Times*, for the installation of a well-equipped plant in Australia to deal with the local ores, which for many years past have been carefully picked and sent to Europe for treatment. The ores, both of South Australia and Queensland, are chiefly ores of bismuth, which contain also wolfram and molybdenum in very small percentages, and the new plant will render it possible to use some of the poorer materials hitherto rejected. Certain of the richer ores of the molybdenum, found in Queensland, can be hand-picked so as to attain a value approaching £300 a ton for shipment to this country.

MEETINGS OF THE SOCIETY.

Ordinary Meeting.

Wednesday evening, at 8 o'clock.

May 12.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry." Sir Robert Abbott Hadfield, D.Sc., F.R.S., will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

May 13.—Sir Charles H. Armstrong, late Chairman, Bombay Chamber of Commerce, "Indian Trade and the War." The Most Hon. the Marquess of Crewe, K.G., P.C., Secretary of State for India, will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

David Sommerville, B.A., M.Sc., M.D., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, "Foodstuffs." Four Lectures.

April 26, May 3, 10, 17.

Syllabus.

Chemical Constitution of Foodstuffs—Proteins—Carbohydrates — Fats — Inorganic Substances — Colloids and Crystalloids—Metabolism—Enzymic Action in the Alimentary Canal.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 10 ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. D. Sommerville, "Foodstuffs." (Lecture III.)

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 8 p.m. (Graduates' Section.) Mr. T. E. Chrimes, "The Running-shed Maintenance of a Locomotive."

Engineers, Society of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. A. H. Barker, "Some Future Developments in Heating and Ventilation."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Mr. W. Allen, "A Summary of the Session's Papers on the Acquisition of Land, Tenure, Rating, and Housing."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. V. A. Smith, "Akbar, the Great Mogul (1542-1605): His Life, Character, and Opinions."

TUESDAY, MAY 11...Faraday Society, at the Institution of Electrical Engineers, Victoria embankment, W.C., 8 p.m. 1. Professor A. W. Porter, "On Von Babo's Law and Kirchoff's Equation for the Latent Heat of Dilution." 2. Mr. D. O. Wood, "The Vapour Pressure of Concentrated Sugar Solutions." 3. Mr. F. H. Campbell, "The Vapour Pressures and Specific Volumes of Binary Mixtures of Volatile with Non-Volatile Liquids." 4. Mr. R. H. Callow, "Reaction Velocity in a Viscous (Heterogeneous) Medium." 5. Messrs. K. C. Browning and C. T. Symons, "Notes on a Convenient Thermostat for Accurate Specific Gravity Determinations and a Gas Pressure Regulator." 6. Mr. E. J. Hartung, "A New Method for Determining the Specific Heat of Liquids." 7. Dr. J. S. Anderson, "An Electromagnetic Vacuum Balance." 8 Dr. E. B. R. Prideaux, "Note on the Neutralisation Curve of Boric Acid." 9. Mr. N. M. Bell, "On the Anodic Solution of Lead." 10. Messrs F. J. Harlow and R. S. Willows, "A Simple Method of Deriving the Gibbs Adsorption Formula." 11. Mr. F. C. Thompson, "The Elastic Strength of Metals."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Animal Spirits." (Lecture II.)

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. F. F. Renwick, "Mysterious Markings; or, what not to do."

Zoological Society, Regent's-park, N.W., 5 p.m. 1. Professor H. M. Lefroy, "The House-Fly Campaign." 2. Mrs. H. L. M. Pixell-Goodrich, "*Minchinia*: a Haplosporidian." 3. Miss E. A. Fraser, "The Head-cavities and Development of the Eye-muscles in *Trichosurus vulpecula*, with Notes on some other Marsupials." 4. Dr. R. Broom, (*a*) "On the Organ of Jacobson and its Relations in the 'Insectivora.' Part II.—*Talpa*, *Centetes*, and *Chrysochloris*"; (*b*) "On the Anomodont Genera, *Pristerodon* and *Tropidostoma*."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Colonel Sir Francis Younghusband, "India and the War."

WEDNESDAY, MAY 12...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. C. R. Darling, "Recent Progress in Pyrometry."

Metals, Institute of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.30 p.m. Sir J. J. Thomson, "The Passage of Electricity through Metals."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. F. Legge, "The Legend of Mithras."

Automobile Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 8 p.m. Mr. A. Stubbs, "Drop Forging and the Automobile Industry."

Electrical Engineers, Institution of (Yorkshire Section), Philosophical Hall, Leeds, 7 p.m. Mr. J. H. Rider, "The Power Supply of the Central Mining-Rand Mines Group."

Auctioneers and Estate Agents' Institute, 34, Russell-square, W.C., 7.45 p.m. Presidential Address by Mr. J. T. Woolley.

Japan Society, 20, Hanover-square, W., 8.30 p.m. Mr. J. C. Hall, "The Structure of Japanese Society under the Tokugawa Shogunate (1603-1868)."

THURSDAY, MAY 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Sir C. H. Armstrong, "Indian Trade and the War."

Auctioneers and Estate Agents' Institute, 34, Russell-square, W.C., 3 p.m. Annual General Meeting.

Royal Institution, Albemarle-street, W., 3 p.m. Professor V. H. Blackman, "The Movements and Activities of Plants." (Lecture I.)

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. Mr. J. S. Dow, "Some Points in Connection with the Design of Searchlights and Projectors and the Visibility of Distant Illuminated Objects."

Iron and Steel Institute, at the Institution of Civil Engineers, Great George-street, Westminster, S.W., 10.30 a.m. Annual Meeting. 1. Mr. F. W. Adams, "Diffusion of Carbon in Iron." 2. Messrs. J. O. Arnold and G. R. Bolsover, "Supplementary Notes on the Forms in which Sulphides may exist in Steel Ingots." (Part II.) 3. Messrs. G. Charpy and A. Cornu, "Researches on Iron, Silicon, and Carbon Alloys." 4. Dr. J. A. Newton Friend and Mr. P. C. Barnet, "Corrosion of Iron in Aqueous Solutions of Inorganic Salts." 5. Dr. J. A. Newton Friend and Mr. C. W. Marshall, (*a*) "Relative Corrodibilities of Gray Cast Iron and Steel"; (*b*) "Note on the Removal of Rust by means of Chemical Reagents." 6. Dr. A. Greiner, "Communication on the Heating of an Open-hearth Furnace by means of Tar." 7. Sir R. A. Hadfield and Dr G. K. Burgess, "Sound Steel Ingots and Rails." 8. Mr. K. Honda, "The Nature of the A_2 Transformation in Iron." 9. Messrs. A. McWilliam and E. J. Barnes, "Brinell Hardness and Tenacity Factors of a Series of Heat-treated Special Steels." 10. Messrs. A. M. Portevin and E. L. Dupuy, "Thermo-electric Properties of Special Steels." 11. Dr. J. H. Smith and Mr. G. A. Wedgwood, "Stress-strain Loops for Steel in the Cyclic State." 12. Dr. J. E. Stead, (*a*) "Detection of Burning in Steel"; (*b*) "Iron, Carbon, and Phosphorus."

3 p.m. Professor H. Hubert, "Recent Progress in the Design of Large Blast-furnace Gas Engines."

FRIDAY, MAY 14...Iron and Steel Institute, at the Institution of Civil Engineers, Great George-street, S.W., 10.30 a.m. Annual Meeting continued.

Royal Institution, Albemarle-street, W., 9 p.m. Rev. E. H. Pearce, "The Archives of Westminster Abbey."

Malacological Society, Burlington House, W., 8 p.m. 1. Mr. G. C. Crick, "On a Dibranchiate Cephalopod (*Plesioteuthis*) from the Lithographic Stone of Bavaria." 2. Mr. J. R. le B. Tomlin, "Description of a New Species of *Zingis* from British South-west Africa." 3. Mr. G. K. Gude, "Diagnosis of a New Species of *Dyakia*."

Astronomical Society, Burlington House, 5 p.m.

Physical Society, Imperial College of Science, South Kensington, S.W., 8 p.m.

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 8 p.m. Professor A. H. Gibson and Mr. W. J. Walker, "The Distribution of Heat in the Cylinder of a Gas Engine."

SATURDAY, MAY 15...Royal Institution, Albemarle-street, W., 3 p.m. Professor F. Soddy, "Advances in the Study of Radio-active Bodies." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,260. VOL. LXIII.

FRIDAY, MAY 14, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 17th, 8 p.m. (Cantor Lecture.) DAVID SOMMERVILLE, B.A., M.Sc., M.D., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, "Foodstuffs." (Lecture IV.)

CANTOR LECTURES.

On Monday evening, May 10th, DR. DAVID SOMMERVILLE, B.A., M.Sc., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, delivered the third lecture of his course on "Foodstuffs."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, May 13th; The Most Hon. the MARQUESS OF CREWE, K.G., P.C., Secretary of State for India, in the chair. A paper on "Indian Trade and the War" was read by SIR CHARLES H. ARMSTRONG, late Chairman, Bombay Chamber of Commerce.

The paper and discussion will be published in a subsequent number of the *Journal.*

EXAMINATIONS.

A new system of publication of the results of the Examinations has been started this year. The candidates fill in a counterfoil attached to the paper on which they do their work; on these counterfoils the result of the examination is marked, and they are returned to the centres as soon as possible. By this means candidates are informed of the result of their examination some weeks sooner than in former years, when they had to wait until the printed results were issued. The results of the March Examinations in the Advanced and Intermediate Stages have now been sent to the centres concerned. The former were posted on April 24th and the latter on May 12th. The Examinations were held from March 22nd to March 31st.

The results of the Elementary Stage will be issued about the end of this month.

AMERICAN MAILS.

Fellows resident in America who may have addressed letters to the Society's office by the mail which should have been delivered in London on the 10th inst., are reminded that, in consequence of the destruction of the "Lusitania" by German pirates, those letters have probably been lost. It is therefore advisable that they should repeat the substance of their communications by a subsequent mail.

PROCEEDINGS OF THE SOCIETY.

TWENTIETH ORDINARY MEETING.

Wednesday, May 12th, 1915; SIR ROBERT ABBOTT HADFIELD, D.Sc., D.Met., F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bashiram, Sabgal, M.A., Assistant Engineer, P.W.D., Amritsar, India.

Sutton, E. Stanley, care of Manáos Harbour, Ltd., 11, Adelphi-terrace, W.C.

Wadleigh, Francis R., 426, Real Estate Trust Building, Philadelphia, Pennsylvania, U.S.A.

Williams, David D., 17, Montpelier, Edinburgh.

The following candidates were balloted for and duly elected Fellows of the Society:—

Balls, William H., Southern High School, Broad and Jackson-streets, Philadelphia, Pennsylvania, U.S.A.

Heath, Principal Lionel, I.E.S., Mayo School of Art, Lahore, Punjab, India.

Lau Chu Pak, Hon., J.P., 1, Babington-path, Victoria, Hong-Kong, China.

Stanley, William, Great Barrington, Massachusetts, U.S.A.

Turner, Walter V., Edgewood Park, Pittsburgh, Pennsylvania, U.S.A.

The paper read was—

RECENT PROGRESS IN PYROMETRY.

By Chas. R. Darling, A.R.C.Sc.I., F.I.C.,
Lecturer in Physics at the City and Guilds Technical College, Finsbury.

In the autumn of 1910 I had the honour of delivering four Cantor lectures before the Society on the subject of "Industrial Pyrometry," which contained an account of the appliances in use at that time. During the intervening period many improvements have been introduced, and many new instruments designed; and it is the object of the present paper to give an account of the chief advances made in pyrometry since the above date.

It is interesting to note, in view of the recognition of the value of scientific research forced upon us by the war, that, apart from the work of Government institutions such as the National Physical Laboratory, and the United States Bureau of Standards, practically all recent progress in pyrometry has been due to the efforts of instrument-makers, and little of importance has emanated from our educational institutions. At the present moment, most of our physicists are absorbed in atomic and molecular physics, to the exclusion of the industrial applications of their science. Hence it has been left to the manufacturers of pyrometers, chiefly in Britain and America, to furnish the improvements in methods, and to extend the applications of high-temperature measurements to the industries. The work accomplished in this direction deserves a much wider scientific recognition than it has received; and it is to be hoped that in the future any funds ear-marked for research will be spent largely on investigations definitely directed to the improvement of our industries. It is satisfactory to be able to state that, as the

result of scientific methods, British makers of pyrometers are not merely independent of other countries, but stand unrivalled in regard to the quality and accuracy of the instruments they supply.

During the period under notice no pyrometers based upon new principles have been introduced, and the advances made therefore relate to methods previously in use, which it will be convenient to consider under separate headings.

Standards of Temperature.

Various investigations of fixed points have resulted in the confirmation, or, at most, slight modification of previously-accepted figures. The table given on page 590 shows the values now generally recognised for purposes of standardisation, in terms of temperatures on the gas scale (omitting fractions).

Up to the highest reading at present obtainable directly on the gas-scale (1550° C.), these standards appear now to be well established. The melting-point of platinum, although arrived at by extrapolation, is probably correct to two or three degrees, and forms a very useful standard for the calibration of high-reading pyrometers.

All the foregoing fixed points refer to pure materials, and considerable errors may arise in graduating instruments unless the substances used are of a high grade of purity. Commercial materials are frequently unsuitable; antimony, for instance, may vary by 10° or more in melting-point from that of the pure metal. To overcome this difficulty, the United States Bureau of Standards now issues materials of certified fixed points, so that any user of pyrometers may check or re-calibrate his instruments with accuracy. This procedure might, with advantage, be followed by our own National Physical Laboratory, which is the centre of accurate pyrometer standardisation in this country. It has been suggested that a better plan is to keep an accurate, certified pyrometer for such purposes, and no doubt this is the case in very large establishments. In places where only two or three pyrometers are in use, however, the expense of a standard instrument, purely for testing, is not warranted; and it would be a great benefit to the small user if materials were available which he could rely upon to check the accuracy of his instruments. Instructions for use could be issued, so that, if they were followed intelligently, a correct result would be ensured.

Thermoelectric Pyrometers.

The past few years have witnessed a great extension of the use of base metals in the construction of thermal junctions. This has been due not merely to the almost prohibitive price of platinum and kindred metals, but to the fact that properly-chosen base-metal couples develop a relatively high E.M.F., and therefore enable a strong and cheap indicator to be used in place of the sensitive instrument required for couples of the platinum series. The chief base-metal couples in use in this country are composed as follows:—

Positive.	Negative.	Highest working temperature.	Maker.
Iron	Constantan	900° C.	All British firms.
Iron-nickel alloy	Iron-nickel alloy of different composition	1000° C.	R. W. Paul.
Nickel-chromium alloy	Nickel-chromium alloy of different composition	1200° C.	Foster Instrument Company.

For occasional readings, the last-named junction may be raised about 100° C. above the limit mentioned. For work at lower temperatures than 700° C., copper-constantan junctions

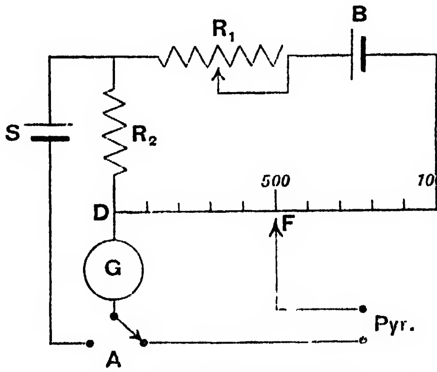

Fig. 1.—Potentiometer Indicator.

are frequently used, as, for example, in measuring the temperature of superheated steam. Numerous other combinations are used, particularly in the United States; amongst which may be mentioned couples of nickel-chromium and

iron-nickel, and iron joined with an alloy of nickel and aluminium.

Considerable doubt has been thrown on the reliability of base-metal junctions by Kowalke,* who investigated a number of couples supplied for commercial purposes by American makers. In all the cases examined sustained heating for twenty-four hours was found to alter the calibration by amounts varying from 20° C. to 130° C., the departure being most noticeable at the higher temperatures used—800° C. and 1000° C. Depth of immersion in the furnace was found to cause discrepancies in the indications, and the general results showed that large errors might arise owing to defects in the couples sent out by the makers. In some cases changes in the structure of one or both of the elements were detected by the aid of photomicrographs. With most of the junctions, however, it was found that prolonged heating induced a practically stable condition, and the conclusions to be drawn were: (1) the couple should be "aged" by continuous heating at its upper temperature limit before calibration; (2) the depth of immersion during calibration should be the same as that obtaining when the pyrometer is in use; and (3) metals which form solid solutions with one another give the best results. Since the publication of Kowalke's work, I have tested an iron-constantan pyrometer which has been in

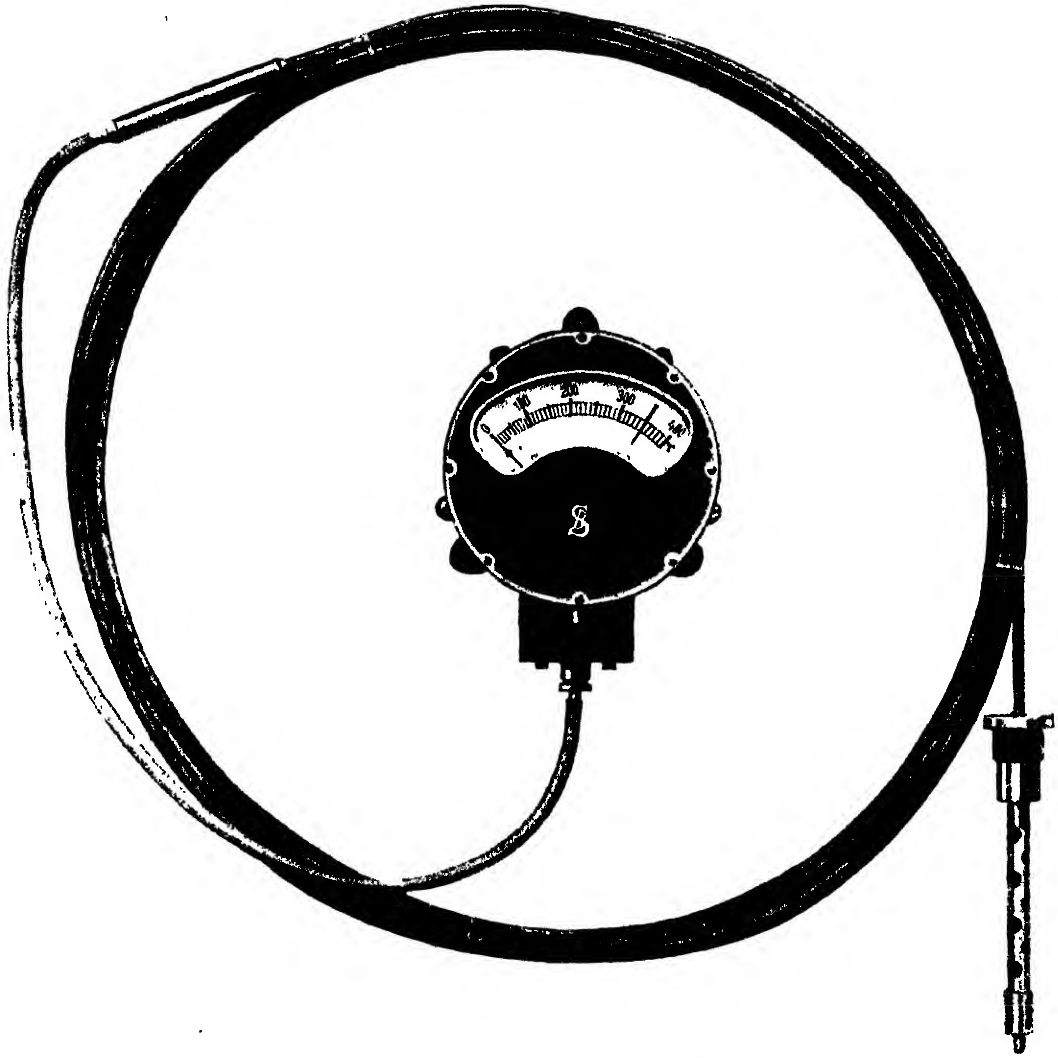

Fig. 2.—Siemens' Pyrometer for Superheated Steam.

* *Transactions* of the American Electrochemical Society, Vols. XXIV. (1913) and XXVI. (1914).

use in my own laboratory for nearly three years, during which time it has been repeatedly heated to 850° C. At the melting-point of zinc (419° C.) the calibration was strictly correct, and at 800° C. the reading was only 5° too low. This pyrometer is of the heavy type, made by welding a constantan rod to an iron tube, and the slight error thus shown after repeated use compares favourably not only with junctions made of platinum and its alloys, but with any type of pyrometer whatsoever. The general experience of users of base-metal couples of British manufacture is that the changes in calibration are much less than those recorded by Kowalke, which, if generally true, would entirely discredit this class of instrument.

An interesting investigation of junctions of carbon and graphite has been made by C. C. Bidwell,* who finds that by the aid of these materials temperatures as high as 2000° C. may be read. It is necessary to subject the junction to a preliminary heating at this temperature before calibration, in order to remove volatile impurities, when constant readings can be secured. Both carbon and graphite can be obtained in thick rods, and can be machined, so that it is possible to build up a robust pyrometer with these substances. If this couple be found to meet the requirements of industrial practice, it should prove extremely useful for temperatures exceeding 1200° C., and may solve the outstanding problem of determining the temperature of molten steel in the ladle. Its utility in experimental work is already established.

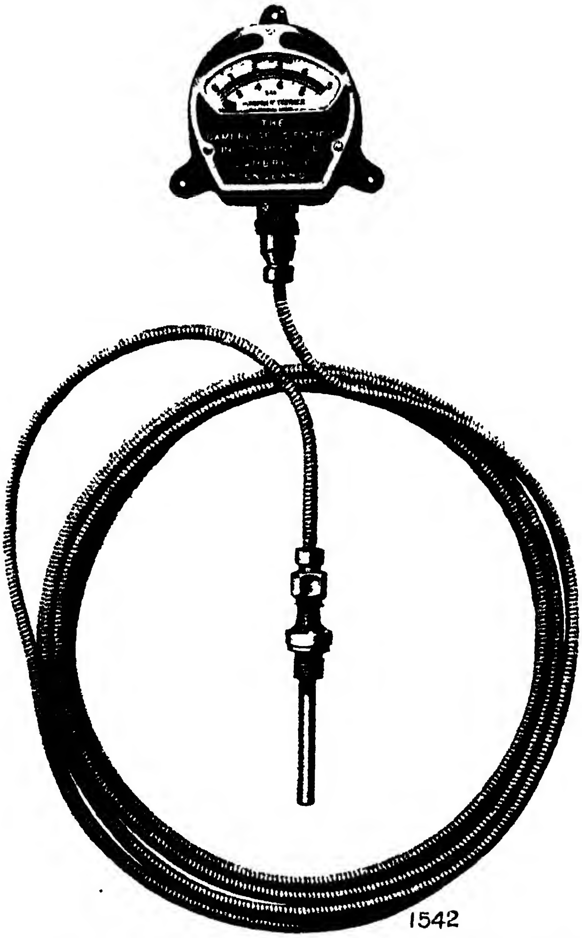

FIG. 3.—CAMBRIDGE SCIENTIFIC INSTRUMENT COMPANY'S PYROMETER FOR SUPERHEATED STEAM.

Several new materials have been introduced to form the protecting sheaths necessary to shield junctions from the corrosive action of furnace gases. Alundum (oxide of aluminium) is now

* *Physical Review*, June, 1914.

used for this purpose; but although it possesses a high melting-point (2050° C.) it is too permeable to gases, particularly at high temperatures, to be of general service. The same remark applies to a new material of the carborundum type, known as "silfrax," recently introduced in the United States. Another material with a carborundum basis, called "silit," is said to give satisfactory results. All the three substances named are brittle, and consequently cannot be subjected to rough usage. A new type of sheath, for use with molten brass or bronze, possesses a tip of molybdenum, connected to a nickel tube covered with a protecting material, so that only the molybdenum and the protection come into contact with the metal. As molybdenum is a good conductor of heat, and only a thin tube is used, a rapid reading of the temperature is obtained, the molybdenum being unacted on by the molten metal. This sheath is said to be entirely satisfactory for this purpose; if so, a troublesome problem in pyrometry may be regarded as solved. Foster's method, in which a junction of Hoskins' alloys is dipped directly into the molten brass, gives rapid readings, but the junction is gradually eaten away.

Much attention has been given by the various makers to the details of indicators, which in almost every case have been improved in the direction of reliability.

A new departure in the method of indicating temperatures in commercial instruments has been made by the Leeds and Northrup Company of Philadelphia, who have adopted the potentiometer principle, previously only employed for accurate laboratory work. The electrical connections of an instrument of this kind are shown in Fig. 1. A current from a two-volt accumulator B, passes through an adjustable resistance R_1, a fixed resistance R_2, and a uniform stretched wire DE. At the point D is attached one terminal of a sensitive galvanometer G, the other terminal being connected to one contact of the pyrometer P. The remaining wire of the pyrometer is fastened to a sliding-contact, F, which may be moved along DE. A standard cell, S, is permanently connected at C, and may be joined to the galvanometer when desired by means of the switch A. To commence with, S is connected to the galvanometer, and R_1 adjusted until no deflection is obtained. The switch is then turned over to the pyrometer, and the slider F moved along the wire until the deflection is again zero, when the fall of potential between D and F will be equal to the E.M.F. of the heated junction. From the relation

$$\frac{\text{E.M.F. of junction}}{\text{E.M.F. of standard cell}} = \frac{\text{Resistance of } DF}{R_2}$$

the E.M.F. of the junction is determined; and as the temperature corresponding to this is known by previous experiments, the point of balance on the wire may be marked with this temperature. Similarly, the whole length of the wire may be divided so as to read temperatures directly. It is essential to accuracy that the fall of potential along DE must not change; and as the voltage of the working cell B falls off with use, R_1 must be adjusted from time to time, so that when the standard cell is coupled to the galvanometer no deflection is obtained. The advantages possessed by an indicator of this kind are (1) great sensitivity, allowing the use of a large scale on which small differences of temperature may be read; and (2) the fact that the readings are independent of the resistance of the pyrometer, and its leads. On the other hand, an adjustment is necessary before taking a reading, and the working cell must be re-charged or renewed from time to time. A skilled observer could obtain closer readings than would be possible with an ordinary indicator, but in the hands of an untrained workman difficulties in use might easily arise.

Another adaptation of the potentiometer principle to indicators has been introduced by the Cambridge Scientific Instrument Company, with a view to obtaining closer readings over a given range. If an indicator be graduated from 0° to 1000°, and the working range be 500° to 1000°, the useful part only occupies one-half of the scale, and accuracy of reading is thereby restricted. If, however, it can be arranged that the pointer remain in the zero position until the pyrometer has reached 500°, the whole scale may then be used for the interval 500°–1000°, thus enabling finer readings to be taken. The way in which this may be accomplished may be understood by reference to Fig. 1. If the galvanometer, G, be replaced by an indicator, and coupled up so that the fall of potential between D and F opposes the movement of the pointer due to the pyrometer, no deflection will occur until this E.M.F. is overcome. If the value of the opposing E.M.F. be equal to that developed by the pyrometer at 500°, the pointer will only commence to move when this temperature is attained, and hence the whole scale may be devoted to the range 500°–1000°. Assuming that the indicator be sufficiently sensitive, it is evident that a full-scale reading could be

obtained for a less interval—say 200°—the commencing temperature being regulated by altering the position of the contact *F*. In one form of indicator arranged on this principle, the changes in the voltage of *B* are automatically compensated by the standard cell; in a simpler form, the standard cell is abolished, and the varying voltage of *B* allowed for by adjusting resistances in a circuit until the indicator, on being switched into this circuit, shows exactly full-scale deflection.

useful ranges on instruments furnished with double scale are appended:—

Junction.	Full Range. ° C.	Special Range. ° C.
Two iron-nickel alloys	0 to 1000	700 to 900
Platinum—Pt. Ir. . .	0 „ 1300	600 „ 900
Two rhodio-platinum alloys	1600	500 „ 1100

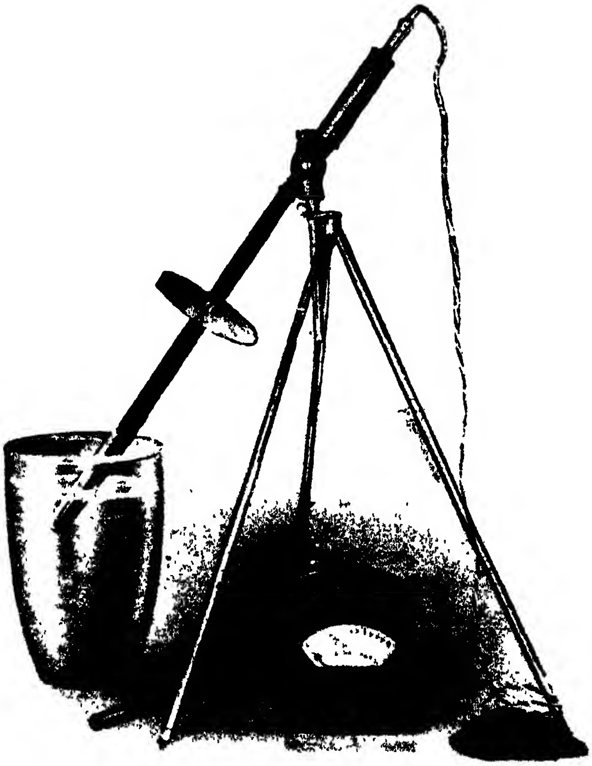

FIG. 4.—FOSTER'S RADIATION PYROMETER FOR MOLTEN METALS.

A similar result to the foregoing is attained by a different method in the instruments made by R. W. Paul. In these, the indicator takes the position of the galvanometer in a Wheatstone bridge, the pyrometer being in the indicator circuit. By adjusting the resistances in the arms of the bridge, a small current from the external battery may be caused to pass through the indicator so as to oppose that due to the pyrometer. This opposing current may, for example, be regulated so that the pointer of the indicator remains at zero until the pyrometer has attained 500°, thus leaving the whole scale available for graduation from 500° upwards. Examples of

Combined with this Wheatstone bridge arrangement is a device for correcting automatically for changes in the temperature of the cold junction. In the four arms of the bridge two of the resistances are of manganin, which are unaffected by temperature changes, whereas the other two are of copper, which alters in resistance on heating or cooling. The bridge is accurately balanced at 20° C., but at any other temperature a small current will pass through the indicator, the direction of which will depend upon whether the resistances have been raised or lowered in temperature. The cold junction is located so as always to possess the same temperature as

the resistances, which are regulated so that the movement of the indicator pointer, when the bridge is out of balance, covers an amount of the scale representing the difference between 20° and the temperature of the cold junction. This compensation is arranged to hold either for full or special range.

indicator unaffected by vibrations is requisite, and can now be supplied by the various makers. Altogether, it will be seen that noteworthy progress has been made in this branch of pyrometry, most of the difficulties which militated against accurate and concordant results having been removed.

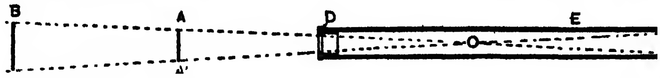

FIG. 5.—PRINCIPLE OF PAUL'S RADIATION PYROMETER.

A mechanical "hold-up" for special range work has recently been devised by the Cambridge Scientific Instrument Company. In this case the indicator possesses a suspended coil, and by turning a graduated head a twist is imparted to the suspension, opposing that due to the current passing from the pyrometer through the coil. By turning the graduated head to a given mark, the zero of the indicator may be made to represent say 500°, and the whole scale used for the remainder of the range.

The general use of superheated steam in engines, including locomotives, has opened a wide field for the useful application of pyrometers. In this instance it is necessary to arrange the pyrometer to withstand pressure, and to provide fittings whereby it may be fastened to a steam-pipe. Thermal junctions of

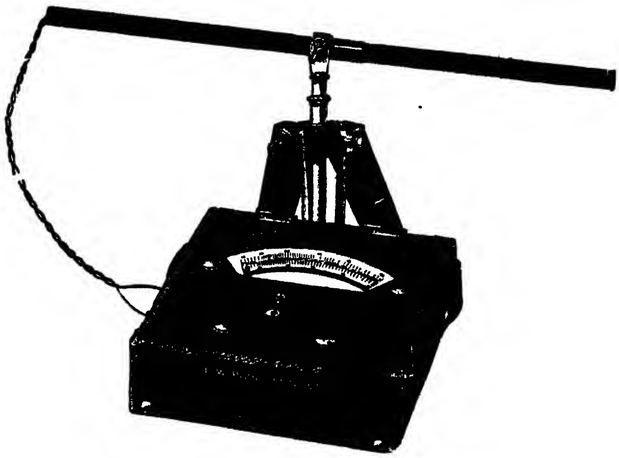

FIG. 6.—PAUL'S RADIATION PYROMETER.

copper and constantan are usually employed, and the arrangement of the fittings is shown in Figs. 2 and 3, which represent instruments of this type made by Messrs. Siemens and the Cambridge Scientific Instrument Company respectively. Similar pyrometers are made by Foster and Paul. In the case of locomotives, an

RESISTANCE PYROMETERS.

There are few changes to record in connection with this class of instrument, the patterns in use five years ago having undergone little modification. Platinum, which is the metal invariably used, has been shown recently by Sir William Crookes to be measurably volatile above 1000° C., and this explains fully why the readings of these pyrometers went astray when a continuous temperature above this figure prevailed in the furnace. For work at low temperatures, such as occur in connection with cold storage, and also for use in chemical operations at moderately high temperatures, the resistance pyrometer is to be preferred on account of its greater accuracy, and its use for such purposes is extending rapidly. An installation, consisting of a number of instruments connected to a single indicator through a switchboard, is now a common feature in cold stores or up-to-date chemical works. By its aid the attendant can read the temperature at any point by switching the pyrometer located at the spot on to the indicator, and the accuracy of the reading may be either 1° or less if desired. For metallurgical

work, resistance pyrometers find an application in cases where great accuracy is essential, and where provision is made to secure a precise adjustment of the temperature of the furnace. A common practice in large establishments is to use thermoelectric instruments for the ordinary work, but to keep one or more resistance pyrometers for specially accurate work, and for checking the various indicators in general use. This is sound practice, as it makes the best use of both systems.

Reference may be made here to the interesting researches of Northrup,* which give promise of an extension of the resistance method to a range of temperature beyond its present limit of 1000° C. Northrup found that certain metals, such as copper, increase steadily in electrical resistance up to the melting-point, and that in the process of melting the resistance is doubled in value, after which the resistance of the molten metal increases uniformly as the temperature rises. It may be possible to devise an instrument in which the temperature is deduced from the resistance of a molten metal; if so, the range of resistance pyrometers could be extended to at least 1400° C., and higher than this if a protecting sheath capable of withstanding a greater temperature could be found. Another possible extension of the resistance method is suggested by the change in resistance shown by pyro-conductors with rise of temperature. These bodies, of which glass is an example, decrease in resistance with rise in temperature; thus alundum, at 1100° C., has a resistance of 6,100 ohms per cm. cube, which falls to 190 ohms at 1600° C.—an average decrease of nearly 12 ohms per degree. A very coarse instrument would readily detect a change of this order, and further investigations in this direction may lead to a pyrometer based on this phenomenon.

* *Journal* of the Franklin Institute, January and March, 1914.

Radiation Pyrometers.

The drawbacks incidental to the use of thermoelectric pyrometers for temperatures exceeding 1000° C. have led to a wide adoption of the radiation method in processes involving readings above this point. The Féry pyrometer, made by the Cambridge Scientific Instrument Company, is extensively used, and has been improved in details. In the early form, a suspended-coil galvanometer was necessary as indicator, owing to the low E.M.F. developed by the junction on which the rays were focused. The use of an alloy of antimony and zinc, in atomic proportions, as one of the junction materials, has enabled pivoted indicators to be used, owing to the greatly increased E.M.F. obtained, which is a great advantage from the standpoint of portability. The gilt mirror formerly used has been superseded by one of a special alloy of higher reflecting power; and the focusing head graduated so that, without sighting, the pyrometer may be focused for any desired distance. Whipple has applied this pyrometer to the determination of the temperature of molten metals by mounting it at the open end of a fireclay tube, the closed end of which is dipped into the metal, and kept permanently in focus. By this means readings as high as 1500° C. have been taken in small ladles, but so far it has not been found possible to apply the method to large masses which cannot be approached closely.

Foster's fixed-focus instrument has also proved quite satisfactory for general workshop requirements, and has found many applications. Fig. 4 shows this pyrometer as used for molten

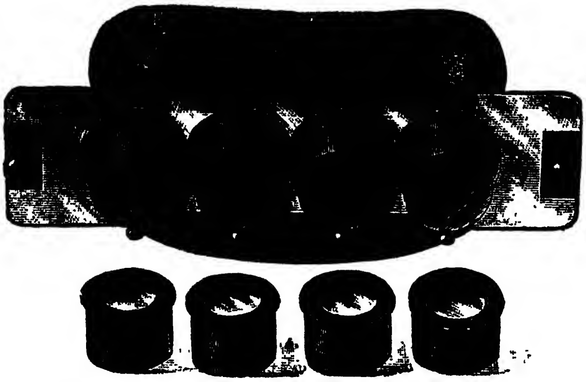

Fig. 7.—Becker's Extinction Pyrometer.

metals, attached to a fireclay tube, the closed end of which is immersed in the material. A feature of this arrangement is the vertical ventilating tube in front of the mirror, which prevents metallic fumes rising from the fireclay tube, in case of breakage, from entering the upper end of the telescope, and thus avoids any damage which might arise from this cause. Being mounted on a light tripod, the instrument is portable, and can be adjusted in height as required. A pivoted indicator is used. A special form of this pyrometer, designed for lower ranges, such as 500° C. to 1000° C., can now be procured. Another form of fixed-focus pyrometer, due to Thwing, has been marketed by R. W. Paul.

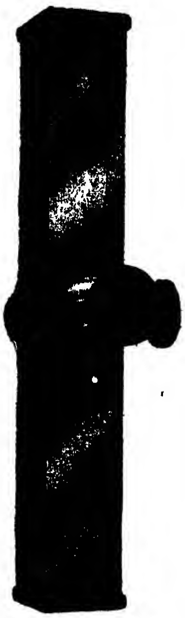

FIG. 8.—ALDER AND COCHRANE'S EXTINCTION PYROMETER.

The principle of working is shown in Fig. 5, where E is a tube containing a polished cone, C, at the apex of which is fixed a thermal junction, T. Rays from the hot source AA' enter the tube at D, and pass into the cone, being finally reflected on to T, which is connected to the indicator. So long as the lines joining the outside of the cone with the extremities of the entrance D, crossing at O, fall within the hot source, AA', the reading will be the same at all distances. Fig. 6 shows the actual pyrometer, mounted on a tripod, with a unipivot galvanometer as indicator, the scale, as in all radiation pyrometers, being divided into temperatures according to the fourth-power law.

The certificates issued by the National Physical Laboratory with radiation pyrometers of all the types mentioned indicate the high degree of skill shown by the makers. The corrections are invariably small, and sometimes non-existent.

Mention may be made here of the results of various determinations of the value of the constant K in the radiation formula

$$E = K(T_1^4 - T_2^4)$$

where E is the energy radiated by a black body in watts per square centimetre. Using the accurate pyrometers now available, the value for K has been found to be $5 \cdot 6 \times 10^{-12}$.

OPTICAL PYROMETERS.

The standard forms of optical pyrometers due to Féry, Wanner and Holborn & Kurlbaum

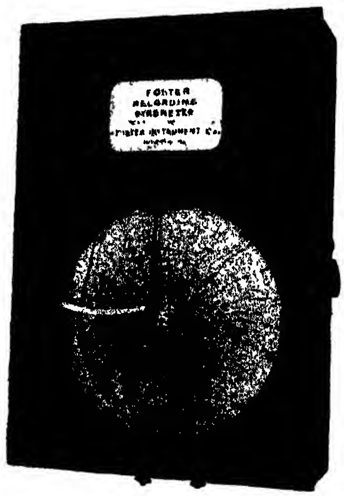

FIG. 9.—FOSTER'S RECORDER.

are now well established, and have been improved in detail for greater convenience of reading in the workshop. A new type of instrument has come into use, based upon the principle of colour extinction. By interposing a solution of correct colour and density between the eye and the heated source, all luminous rays may be extinguished. The instrument sold by F. E. Becker & Co. is shown in Fig. 7, and consists of an eye-shade, in which prepared cells, corresponding to known temperatures, may be fitted. Double vision is used, being better suited to prolonged observation. To control a furnace so as to attain a desired temperature, observation is made through the appropriate pair of cells from time to time, until a faint red image is seen, when the heat supply is regulated so as

to maintain a constant temperature. A second pair of cells in the eye-shade correspond to a temperature a few degrees higher than that required, and on looking through these the field should appear dark. In this manner a very close approximation is obtained, and the apparatus finds a useful application in the hardening of steel and other processes which involve the production of a steady temperature. A form of this pyrometer has been issued consisting of a single cell, in which the thickness of the layer of liquid may be adjusted, and graduated in temperatures corresponding to the thickness.

A second form of colour-extinction pyrometer has been introduced by Alder and Cochrane (Patent No. 27,633, 1913). This is shown in Fig. 8, and consists of a small telescope, the rays through which are intercepted by a coloured prism, which may be moved up and down so as to interpose any desired thickness in the path of the rays. In using the pyrometer, the heated object is focused in the telescope, and the prism moved until a completely dark field is obtained. A temperature reading is then indicated opposite a fixed pointer on a scale which moves with the prism. Using this instrument on a filament lamp, I have found a good agreement in the readings obtained by different observers; and being simple in construction and small in size this pyrometer should prove very useful to foremen and others in charge of furnaces. To increase the range, a piece of suitably tinted glass is inserted in the eyepiece, readings being taken from a scale prepared with the glass in position.

A promise of a new form of optical pyrometer is conveyed in a paper read by Paterson and Dudding before the Physical Society in March, 1915. They showed that the temperature of many metallic substances could be measured accurately by matching the colour against that of a black body until equality was obtained, the temperature of the black body being varied until the colours, viewed in the field of a Lummer-Brodhun photometer, were identical. Filament lamps, with an ammeter and rheostat in circuit, were brought to colour equality at various current strengths with the standard black body, the temperature of which was assigned to the filament at each adjustment. The lamps thus became secondary standards, a given current corresponding to a given temperature. Using a carbon filament lamp thus standardised, and adjusting it to colour equality with platinum at its melting-point, the temperature indicated was 1750° C.—a very close approximation to the accepted figure. We may reasonably expect our instrument-makers to produce an optical pyrometer on these lines, suited to industrial purposes.

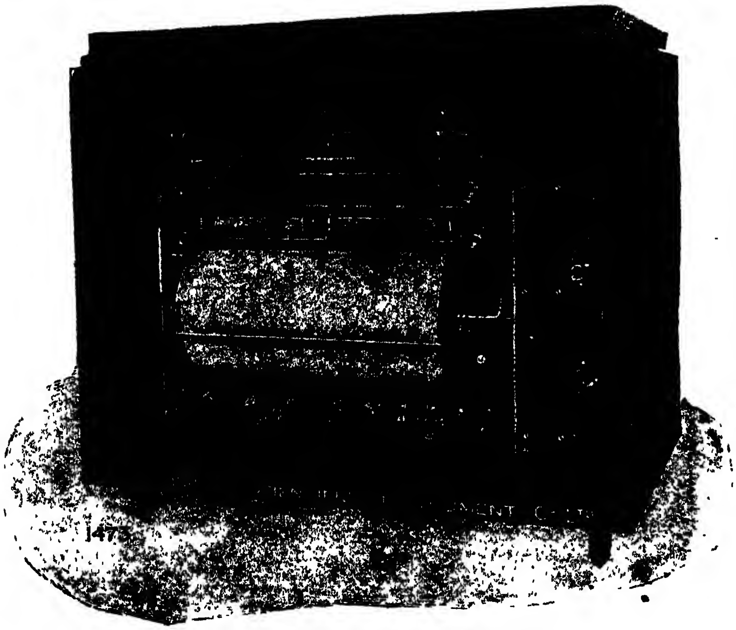

Fig. 10.—Double Thread Recorder.

Mr. Lovibond has suggested a colour-matching pyrometer of a different kind. Using a frosted glass field illuminated by a filament lamp as a standard surface, and interposing tintometer glasses, equality of tint could be obtained with

a heated source at a lower temperature. Standardisation could be carried out by means of a black body at known temperatures, and the values assigned to the tinted glass combinations required to produce equality of hue. In a trial of this method Mr. Lovibond and myself found it to be very sensitive; but, so far as I am aware, he has not followed it further.

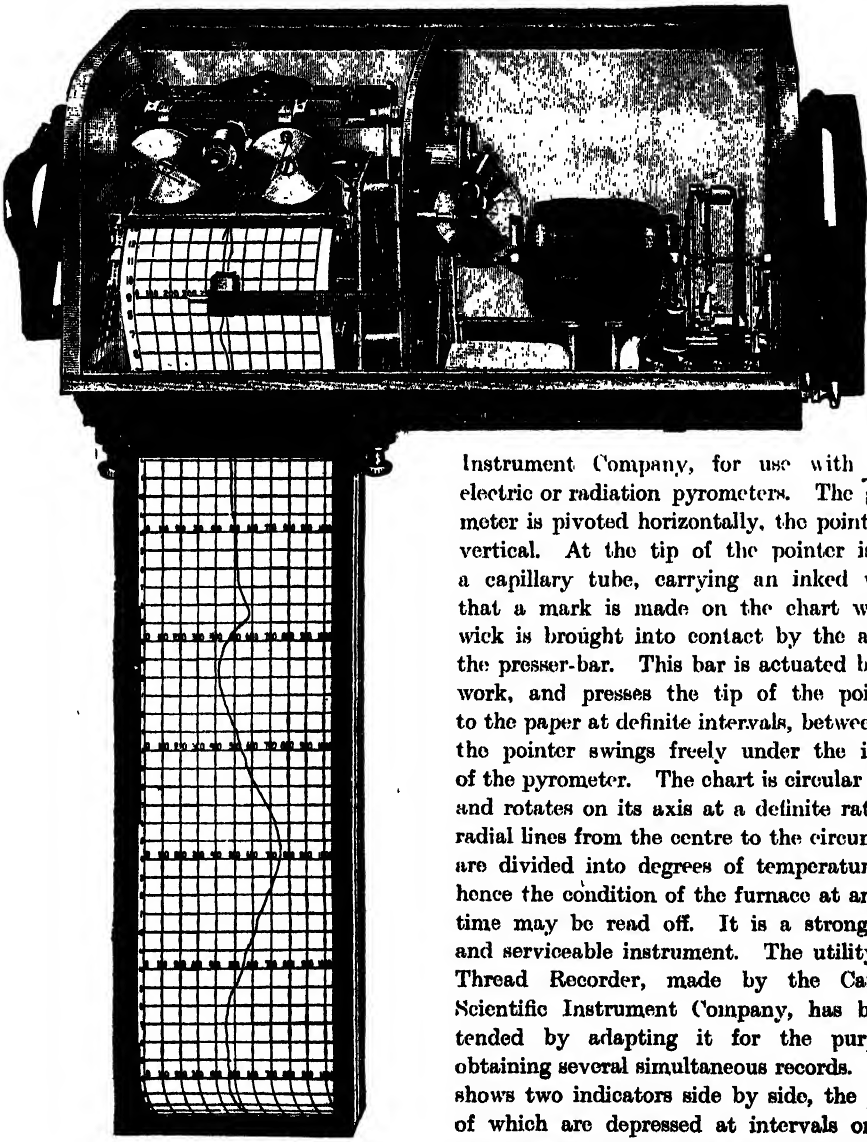

FIG. 11.—PAUL'S RECORDER.

RECORDERS.

The advantages of continuous records of furnace temperatures have been widely recognised during the last few years, and in consequence developments in this branch of pyrometry have been extensive. The modern form of the Roberts-Austen photographic recorder, made by the White Instrument Company, is used in many places; but the modern tendency is in favour of inked records, which are always visible, and require no photographic treatment. A brief description of the newest forms must suffice on the present occasion.*

Fig. 9 shows the recorder made by the Foster Instrument Company, for use with thermo-electric or radiation pyrometers. The galvanometer is pivoted horizontally, the pointer being vertical. At the tip of the pointer is placed a capillary tube, carrying an inked wick, so that a mark is made on the chart when the wick is brought into contact by the action of the presser-bar. This bar is actuated by clock-work, and presses the tip of the pointer on to the paper at definite intervals, between which the pointer swings freely under the influence of the pyrometer. The chart is circular in form, and rotates on its axis at a definite rate. The radial lines from the centre to the circumference are divided into degrees of temperature; and hence the condition of the furnace at any given time may be read off. It is a strongly-made and serviceable instrument. The utility of the Thread Recorder, made by the Cambridge Scientific Instrument Company, has been extended by adapting it for the purpose of obtaining several simultaneous records. Fig. 10 shows two indicators side by side, the pointers of which are depressed at intervals on to an inked thread, which touches the chart and makes a mark. A double chart is mounted on a single drum, which rotates by clockwork, and a separate pyrometer may be coupled to each indicator. When four records are required

* For a fuller account of recording pyrometers, see a paper by the author in the *Transactions* of the Faraday Society, 1914.

simultaneously, two threads, wetted with inks of different colour, are used; and by an automatic arrangement the pointer may be made to descend on each thread in turn. Two pyrometers are connected to each galvanometer, and are brought into circuit in turn, so that the records of each appear in a different colour; and thus four records in all can be secured on the same chart. It may be used for thermoelectric or radiation pyrometers. The Leeds and Northrup Company, of Philadelphia, have introduced a recorder which is actuated by an electric motor, instead of clockwork, and which may be used for resistance or thermoelectric instruments. A boom from the coil of a galvanometer is placed between a system of levers, and when on either side of the central position it enables the levers to engage and to cause a disc to rotate. The effect of the rotation is to readjust matters so that the boom is restored to the central position. Used with a resistance pyrometer, the moving disc alters the resistance in one arm of a Wheatstone bridge until a balance is obtained, when the boom assumes the central position and the levers fail to engage. When connected to a thermoelectric pyrometer, the movement causes an arm to move over a potentiometer wire (Fig. 1), until the E.M.F. due to the pyrometer is counterpoised, when the boom will become central. The movements of the disc are communicated, by suitable mechanism, to a pen moving over a chart. This recorder is much used in the United States, but has not yet been adopted in Britain.

The motor-drive has also been applied in the recorder made by R. W. Paul, which is illustrated in Fig. 11. A special device is used to ensure a constant speed of rotation in the motor, which, by suitable gearing, actuates the chart and presser-bar. The pointer of the galvanometer is pressed periodically on to an inked ribbon, beneath which is placed a thin metal rod over which the chart passes. The speed of the various movements may be altered by changing the gear. A unipivot galvanometer is used when records of thermoelectric or radiation pyrometers are being made; and when a resistance pyrometer is employed a Harris indicator is used instead of the galvanometer. The lower extension of the recorder enables a considerable length of chart to be inspected. Multiple records may be secured with any type of pyrometer; and specially useful features are: (1) The provision of metal-faced joints in the cover, which makes the recorder dust-proof; (2) the construction of the apparatus in separate units, each of which is easily replaceable; and (3) the use of the motor in place of clockwork, which enables a greater power to be used in actuating the various parts.

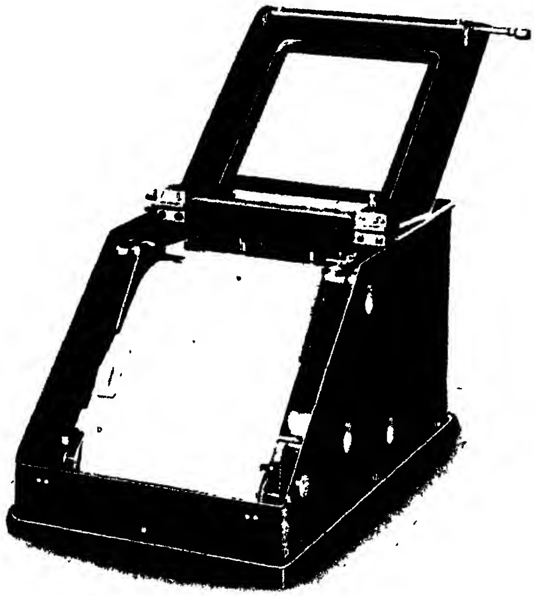

FIG. 12.—SIEMENS' RECORDER.

Messrs. Siemens and Company, who were the first to introduce an ink recorder, have recently

introduced several improvements in their instrument. The case is now constructed entirely of metal, jointed so as to be dust-proof. A pivoted galvanometer is used, and the pointer, made of thin metal, is pressed down periodically on to an inked ribbon, beneath which is placed a metal knife-edge over which the chart passes, so that a small dot is made at each contact. The case is made with a sloping front in which a window is inserted (Fig. 12), thus enabling a large portion of the record to be seen at a glance. This front is hinged to permit of access to the clockwork, which is made in three separate parts, controlling respectively the forward movement of the chart, the ascent and descent of the presser-bar, and the movements of the rollers on which the record-paper is wound. Robust construction and small size are features of this recorder.

Conclusion.

It will be seen from the foregoing that a substantial advance has been made in the production of instruments for measuring and recording high temperatures since the subject was previously before the Society. At the present time, when all and sundry are in search of methods of adding permanently to our industries, the example furnished by the manufacture of pyrometers may be cited as a useful guide to success in this direction. All the establishments in which pyrometers are made in this country are under the direction of thoroughly skilled scientific men, who are constantly devising new instruments with a view to greater efficiency and a wider field of application. All are in close touch with the National Physical Laboratory, which has proved invaluable to them in regulating the calibration of their instruments, and securing a uniformity which is now comparable to that which exists in thermometers. The result is a thriving and constantly extending industry, not threatened by foreign competition, and not in need of artificial props to ensure its success. The instruments exhibited to-night, all of British manufacture, cannot be surpassed, or probably equalled, by any other country; and are examples of what may be accomplished by the intelligent application of science to industry.

[Apparatus in illustration of the paper was exhibited by the Cambridge Scientific Instrument Company, Mr. R. W. Paul, the Foster Instrument Company, Messrs. F. E. Becker & Co., Messrs. Cochrane & Co., and Messrs. Townson & Mercer.]

DISCUSSION.

The Chairman (Sir Robert Abbott Hadfield, D.Sc., F.R.S.), in opening the discussion, said his first experience of a pyrometer was that of a blacksmith named "Joe." Joe was a very good pyrometer indeed. He (the Chairman) used to take him various pieces of steel in his earlier days of experiments on alloy steel; and it was marvellous how very closely Joe could take the temperatures. It only showed how high the human intelligence was, even if not aided by scientific apparatus. With reference to the interesting subject of pyrometers, when looking back during the last twenty years it was astonishing to note the progress which the development of that branch of science had enabled metallurgists to accomplish. To-day not only did the pyrometer represent highly specialised scientific apparatus, but it was practical, and with hardly any practice could be handled with success by those who had had even but little experience. He had been recently looking over one of his own papers read before the Institution of Civil Engineers in 1899, "The Influence of Casting Temperature upon Steel," in which the question of determining temperatures was at that time dealt with. The question of how to estimate temperatures by accurately observing the various shades of colours in heated objects was then being discussed. No doubt that method was useful; human eyes, however, varied, and two observers trying to observe the temperature of the same heated object generally arrived at quite different conclusions. It was therefore in that respect that the great work done by the well-known Frenchman, Professor Henri le Chatelier, had proved invaluable. Professor Le Chatelier was unusually modest. Beyond expressing gratification at the result of his researches, he himself had not claimed to be a pioneer. On the other hand, however, all those who had studied the question knew that, had it not been for his work, it was more than probable that this branch of metallurgy would not be in the high state of perfection it had now reached. Speaking in a general way, Wedgwood in 1782, with his fireclay pyrometer, was probaby the first to call attention to the importance of correctly determining temperatures. That was the result of his work in connection with pottery. There was then a long interval, during which little was done until the late Sir William Siemens took up the question of determining temperatures by means of measuring the varying electrical resistance of platinum wire submitted to different temperatures. Another of his methods was the use of a copper ball placed in the furnace the temperature of which was desired to be obtained. The ball was taken out and rapidly quenched, the rise of temperature of the water in which the ball had been immersed being observed; from that a rough determination of the temperature was obtained. That method was used for a long time with success. Le Chatelier then came forward with his remarkable scientific work, and practically

started the modern electric resistance pyrometer. Excellent work was done in this country by Sir W. C. Roberts-Austen—who was ably helped by Mr. H. C. Jenkins—with his recorder, and also by Mr. H. L. Callendar, by whose accurate instrument it was possible to determine temperature to exceedingly fine points, less than 0·1 of 1° C. As showing the extremes of temperature which had been measured, it might be mentioned that Professor K. Onnes had been down to within 1½° of the absolute zero. On the other hand, Mr. O. Lummer claimed to have reached as high as 6000° absolute (about 5800° C.), by impregnating the carbons and the arc, and working it under high pressure, that artificial temperature of course approximating to that of the sun. The low temperatures reached by Professor Onnes had brought out some remarkable physical facts—including the almost complete absence of electrical resistance in certain metals at those temperatures. Dr. Whipple, of the Cambridge Scientific Instrument Company, had done most useful work in developing the manufacture of both electrical and optical pyrometers, the latter being a comparatively new application and now largely made use of; also Johnson and Matthey, who had been to such great pains in providing pure platinum and platinum alloy ingots of the correct composition; and Dr. G. K. Burgess of the United States Bureau of Standards, Washington, D.C. Incidentally, he was glad to say that Dr. Whipple, acting under strong advice which he put before him, was now in a position to turn out pyrometers for the supply of which we had hitherto been dependent upon the Continent. They were now "made in England." In 1904 an excellent exhibition of pyrometers suitable for metallurgical work was held before the Iron and Steel Institute. Fifteen different kinds of electrical and optical instruments were exhibited, and a useful discussion took place, so that anyone who wished to refer to what was done up to that date, 1904, would find full references and information, including an excellent bibliography. Nearly all the developments of special steel were due to the possibility of now being able to determine temperatures varying from a few degrees to 1200° C. or more. The manufacture of modern armour, projectiles, guns, material, and so on, was now practically dependent upon accuracy of temperature observation. In that respect it might be of interest to read the following from former papers of his own: "With regard to the sensitiveness of iron to changes of temperature 'upwards,' that was in the form known as 'carbon steel,' the fact pointed out by Mr. S. N. Brayshaw in some excellent research work carried out a few years ago, might be mentioned, namely, that at certain physical temperatures a difference of even one degree Centigrade would considerably modify the physical qualities of the steel being treated. Mr. Brayshaw had given good evidence of that in his work. Moreover, it was known that ordinary carbon steel of tool-steel grade quenched at 725° C. would bend considerably, and had a Brinell hardness number of 228. Quenched at 735° C., the same material would only bend 1°·5, the hardness number being increased to 512. Quenched at 740° C., or only 5° C. higher, the bend was *nil*, and the hardness number was increased to the high figure of 713. Thus there was the remarkable fact that by increasing the temperature only 15° C., one had the phenomenon of complete hardening. The small difference of 15° C. (27° F.), within which range hardening or non-hardening results occurred, represented no more than the change in temperature between a spring and a summer day, yet such slight differences in temperature entirely revolutionised the structure of steel. As a further illustration of the significance of accurate temperature determination, it had been pointed out by Professor S. W. J. Smith, F.R.S., and Mr. J. Guild, in an excellent paper entitled "A Thermo-magnetic Study of the Eutectoid Transition Points of Carbon Steels," that in a difference of only about 4° Centigrade, complete revolution took place in the magnetic qualities of iron. For example, the thermo-couple temperature was kept steady for several minutes at 733° C. in one case without alteration in the magnetometer deflection which differed very little from that at 730° C. The furnace temperature was then raised very slightly, and, *before* the thermo-couple reached 734° C. a rapid fall of magnetisation set in. In other words, that important revolutionary change in iron could only be determined by the aid of very accurate pyrometers. There was still one domain in which we were not very sure about temperature observations, that was when we got up to 1400° C. and higher. Molten mild steel had a temperature of about 1580° C. Whilst it was not impossible to determine that accurately on small specimens, that was in laboratory work, there were still no very correct means of determining temperatures in fluid steel of large mass. That same difficulty therefore still existed which he had called attention to in the discussion on Sir William Robert-Austen's paper on his recording pryometer before the Iron and Steel Institute in 1893, that was to say, couples exposed to high temperatures were liable to become very brittle and, when immersed in fluid steel, disintegrated. Whilst in optical pyrometers they gave useful service, there were many sources of inaccuracies in such observations still to be cured. With reference to what were called high temperatures, and showing how puny they were, Dr. Northrup had pointed out that Arrhenius speculated that the petty ranges of temperature in which matter was studied represented about one-sixty thousandth of the total range of temperature in which the matter of our solar system existed. Sir William Roberts-Austen, in the discussion of one of his papers, suggested, as an answer to a question put by Dr. Stead, that the end of the couple might be protected by a cap of zirconium, or by some metallic cap not actually touching the couple. This had not, however, been found of

service in practice, so there was still room for other metallurgists at the present time to improve considerably the practice in this respect. Whilst speaking on the question of Centigrade temperatures, it would be of the greatest service throughout the world if that method of indicating temperatures could be accepted instead of that occasionally done of using Fahrenheit or other scales. In American technical and even scientific papers reference was often made to temperatures in Fahrenheit scale. This was most perplexing, and he was sure those who learnt to think in Centigrade temperatures would never regret it, that method being in every way superior to the older one. It would be of great advantage if all countries came to an agreement to abolish the Fahrenheit scale altogether. He should like to refer to the excellent work being done by the National Physical Laboratory, showing that this country was alive to all the necessary advances to be made in this scientific work. Under Dr. Harker's able guidance they were investigating the following points, amongst others, relating to temperature determination: (*a*) fundamental temperature scales; (*b*) proposed international thermo-dynamic scale as realised through the intermediary of the resistance thermometer; (*c*) high temperature scales; (*d*) thermal conductivity and emissivity of heat insulators; (*e*) heat loss from surfaces; (*f*) general research on refractories; (*g*) specific heat of gases at high temperatures; (*h*) specific heat and latent heat of fusion of metals. In a general way, speaking from many years' experience, the following represented the experience of the laboratories in Sheffield. With reference to the best form of couples, nothing had been found for all-round service to supersede platinum and platinum-rhodium. There were some good base metal couples, but they were not serviceable for high temperatures. He found it best to use resistance wires of the platinum alloys throughout. The use of those couples was not so expensive as might at first sight seem to be the case, because the scrap platinum from high temperature work was useful for low temperature work. With regard to the various forms of pyrometer instruments, platinum resistance pyrometers were too sluggish for quick readings, not suitable for high temperatures, and were costly to repair. It had been found that the thermoelectric type was the best. The vital point about those had been to get an instrument of sufficiently high resistance made up of a material which would not vary with fluctuations of atmospheric temperature. High resistance was absolutely necessary to swamp the changes in resistance of the circuit when using different lengths of couple. Makers were now waking up to this, and the Cambridge Scientific Instrument Company, Siemens Brothers, and the Beighlee Company of America, were found to be quite satisfactory in that respect. Carpentier, of Paris, also made an excellent instrument, having 1,000 ohms resistance, entirely of German silver, and giving a scale 18 ins. long. It had been found essential for accuracy to keep the instrument in a fixed position and calibrate it *in situ*. With regard to recording pyrometers, there were very few instruments on the market of sufficiently high resistance, and nothing had been found to beat the Roberts-Austen photographic recorder, made by the White Instrument Company, for serviceability. With regard to calibration, he strongly emphasised the desirability of calibrating with standard melting and boiling points, in preference to relying upon the makers' calibration or on standard couples. As an example of the cost of platinum and platinum-rhodium wire as used in modern pyrometers, he might say that his firm, in 1913, spent on platinum and platinum-rhodium wire £370, in 1914, £415, and the expenditure for this year would probably be about £600. They made many thousands of determinations each week. If any one of these were inaccurate it would mean bad work and the loss of hundreds of pounds. That would give some idea of the importance of pyrometer work. Before leaving that particular aspect of the subject reference might be made to the important question of the necessity of thoroughly and accurately standardising the various instruments and apparatus employed in determining high temperatures. That matter had been very fully dealt with in a most valuable paper by Dr. E. F. Northrup in June, 1912, entitled "Temperature and the Properties of Matter." Dr. Northrup pointed out the excellent work done in platinum resistance pyrometry by the Bureau of Standards, Washington, D.C.; Dr. G. K. Burgess had given most valuable aid in this branch of science, and was to be heartily congratulated on the work he had accomplished. In the above-mentioned paper Dr. Northrup pointed out the fixed temperature points at which standard substances melt, and which formed a temperature scale by which temperature-measuring devices may be calibrated, as given in the following list:—

Ice, m.p.	0·0°
Water, b.p.	100·0°
Naphthalene, b.p.	217·7°
Benzophenon, b.p.	305·4°
Cadmium, m.p.	320·2°
Zinc, m.p.	418·2°
Antimony, m.p. (in CO)	629·2°
Silver, m.p. (in CO)	960·0°
Gold, m.p.	1062·4°
Copper, m.p. (in CO)	1082·6°
Diopside, m.p.	1391·2°
Nickel, m.p. (in N_2)	1452·3°
Cobalt, m.p. (in N_2)	1489·8°
Palladium, m.p.	1549·2° within ± 2° C.
Platinum, m.p.	1755·0° within ± 5° C.

With those fixed points assigned, any thermo-couple of platinum and platinum-rhodium might have its curve of temperature against thermal E.M.F. determined in any part of the world, when it in turn became a secondary standard for the

measurement of temperature to the melting-point of platinum within an accuracy at the upper limit of approximately 5°. In the paper already mentioned, which he (the Chairman) read in 1899 before the Institution of Civil Engineers, he referred to the fact that at that time it was stated by the able American metallurgist, Mr. H. H. Campbell, in his excellent paper "On the Open-Hearth Process," that even a difference of 20° C. to 30° C. caused considerable changes in the behaviour of molten steel during casting. Although that had not entirely been borne out in practice there was no doubt something in the claim. It would therefore be understood how important it was that a thoroughly practical pyrometer should be perfected, so that small differences at high temperatures should be enabled to be detected. Mr. Campbell stated that the addition of 100 lbs. of scrap to a seven-ton bath of steel would cause the temperature to fall about 16° C. or 20° C., and that change of temperature was perceptible to the naked eye. Speaking of temperatures by colour scale, he (the Chairman) had prepared the following information in comparison with the figures given by other observers. It might be of interest to give a table of the figures:—

Table of Temperatures by Colours.

Hadfield.		Pouillet		Bowker.	
Colour	Temp.	Colour.	Temp	Colour	Temp.
	°C.		°C.		°C.
White (not welding heat)	1240	White	1300	White	1204
High yellow	1130	Orange heat	1100	Very bright red	1010
Yellow	1081	Cherry red	800	Bright red	926
Low yellow	971	Red heat	525	Full red	804
Bright red	923			Red heat	650
Medium red	795				
Blood red	667				

Column No. 1 represented his results obtained by means of a Le Chatelier pyrometer, suitably protected in the furnace. That pyrometer was an admirable one so long as it did not come in contact with molten metal. Column No. 2 represented similar comparative temperatures taken from Pouillet's tables. Column No. 3 represented comparative temperatures prepared by the American expert. Finally it would be seen how much modern metallurgical progress, especially with regard to alloy steel, depended upon the accurate determination of the temperature employed.

Mr. Charles E. Foster complimented the author upon the stress which he had laid on the practical application of the pyrometer. The temptation of anyone with the high technical qualifications of the author must be to examine and dwell upon the ingenious and pretty pieces of design rather than direct and simple application to industrial processes. So far as his own experience went, he thought the pyrometer-maker was ahead of the furnace-maker in so far as the control of temperature was concerned. The pyrometer-maker could measure to a finer degree of accuracy than the furnace-maker could make a furnace to maintain that temperature. Although he did not want to shift the blame on to the shoulders of the furnace-maker, he thought it was up to the latter to make the next move. It was a very difficult question for the instrument-maker to answer as to what instrument the user should have. As a physicist, the maker was tempted to offer a thing having the higher intrinsic accuracy, but that might not necessarily produce the best result in the hands of the user, because the user might not be able to give it the right kind of conditions of use. With reference to the question of stability of the base metal thermo-couple junction, he thought the term "base metal" an unfortunate one. It was used in contradistinction to the "noble metals"—platinum and its alloys, but it must not be base in its performance. In order to secure a base metal thermo-couple which was going to be stable, a great deal of refinement had to be given to the alloys before they were used. They were base in the sense that they were cheaper, and so a much more mechanically robust thermo-couple could be used, but as much care had to be given as was given originally to the refinement of platinum and its alloys, and produced such a good pyrometer in the hands of Le Chatelier and Sir W. Roberts-Austen. There was one point about the base metal thermo-couple which had to be borne in mind, and that was that it usually oxidised much faster than the noble metal. In the noble metal the chief danger was contamination either by furnace gases and metal vapours in the furnace gases, or from the alloy (perhaps 10 per cent. iridium with platinum) in the platinum wire. With base metal

thermo-couples that difficulty did not arise. Oxidation and the mechanical fracture of the wire appeared to be the usual end of the life of the base metal thermo-couple, and that, in his experience, generally occurred long before the contamination had reached anything detectable within commercial limits. The usual thing which happened with a properly-made base metal thermo-couple was a satisfactory reading for one hour and no reading at all for the next hour. That might be annoying, but on the other hand it saved the danger of a reading which might be out as much as 5 per cent. without giving any other indication of its error—and that did sometimes happen with platinum.

DR. J. A. HARKER agreed with the Chairman as to the debt metallurgists owed to Le Chatelier. It was quite true there was no more modest man who had received less recognition for very important achievements. Passing to the work of Kowalke, one important thing to remember in connection with the base metal thermo-couple, was that possibly some of the sins of such an instrument had been due to the fact that its dimensions were altogether different, in ordinary practical cases, from the wires which metallurgists had formerly been accustomed to use in the way of platinum alloy couples. The criticism applied more strongly if the outer tube happened to be made of a metal which was a good conductor. He believed a lot of the difficulty with regard to certain types of pyrometer was not due to inherent lack of homogeneity in the wires themselves, but very often was due to lack of sufficient immersion to give the true temperature of the part which really mattered. The question of alundum was interesting, but he was afraid the Norton firm had not got over the difficulty of getting the tubes sufficiently gastight. Some time ago that firm announced that they had made a successful experiment in which an enamel could be put on to the tubes which would make them practically serviceable as protectors for porcelain. He hoped they would succeed, but it was a very difficult matter. The author mentioned fused magnesia as a possible tube. He (the speaker) was afraid that that was not the cure-all. Both magnesia bricks and magnesia in almost every state seemed to have a weak place somewhere about 1200°, though above and below that temperature its indications were correct. With regard to the volatility of metals, Sir William Crookes's experiments showed a good deal, but it was not perhaps generally known that some things were volatile even at much lower temperatures. For example, a little silver would be fatal to a resistance thermometer. Supposing a globule of silver was dropped down the porcelain tube of a resistance thermometer, and it was heated for an hour to 700° C., it broke down the whole of the insulation completely.

MR. HENRY C. JENKINS remarked that pyrometers were comparatively recent inventions. He remembered, as late as 1894, Sir William Roberts-Austen going with a party down to Woolwich Arsenal where they were shown one of their prize possessions which was then being used in connection with gun forgings. The party were shown the "prize" with a good deal of pardonable pride and were asked to calibrate it. The result showed it was about 100° or 150° out of true! That did not matter much at the time, because then people were measuring temperatures by "Joe's" method, and the instrument was of course being used to repeat certain readings. Still, that result made the Arsenal people look rather sick, but they went on unabashed. One was glad to hear that the United States Bureau of Standards was doing such good work. The Geological Survey of that country also had done a great deal, especially Mr. Karl Barée, who, in the eighties, investigated the platinum alloys so thoroughly that it made metallurgists feel that they could rely on those alloys with a good deal of certainty. One point with regard to Kowalke's work was that it was very difficult to make alloys like constantan absolutely uniform. He thought some of the results of Kowalke were really due to his having had wires which were not absolutely uniform in texture. A very small difference in composition with those alloys would very much alter the E.M.F. obtained from those thermo-couples. A slight want of uniformity would account for a good deal if one was not careful to heat one's piece to exactly the same place. He had been much interested in the reference to Mr. Bidwell's work with the carbon graphite junctions. It so happened that in the Royal Mint laboratories, about 1894, he (the speaker) had actually tried two carbons of different materials in order to get thermo-junctions from them. The results were not very favourable, and it was not thought worth while to publish them; but even a piece of coke and a piece of stick charcoal would give a very decent thermo-couple. It could indicate temperature up to about 3000° C., but it was found there was a neutral point at a very inconvenient position in the scale, and that caused him to drop any further work in connection with it. The question of the porosity of the sheaths was very important. A little metallic vapour was fatal to any accurate reading. One might as well not only give up the experiment, but throw the wires away at the same time. With regard to the issue of materials which would give fixed melting-points, he was afraid not much good would be done except with pure materials. Anything like silicate was quite useless. The melting-points were quite indefinite and the cooling-points somewhat difficult to see. There was a very wide field for radiation pyrometry, but he was afraid there was always a difficulty in connection with that of very often looking at a different thing from that of which one was trying to measure the temperature. For instance, the surface of a ladle of steel was a very different thing indeed from what was inside it.

Mr. William F. Beardshaw said, with regard to the Chairman's reference to "Joe," it was quite remarkable how accurately men could gauge temperatures without the aid of any instrument. Although his firm had three or four different pyrometers ready for use, it was not always found necessary to use them, because men who were accustomed to handling steel every day could tell the temperature to within 20 degrees without their aid.

The Author, in reply, said he quite agreed with the Chairman that metallurgists owed almost everything with regard to modern pyrometry to Le Chatelier. He also agreed with Sir Robert with reference to the use of the Fahrenheit scale. He had really prepared his diagram in Fahrenheit for the benefit of those who could not think in degrees Centigrade. He believed it was the fact that in many departments in Woolwich Arsenal at the present time the degree Centigrade was not recognised. With regard to the term "base metal," he had tried for a long time to discontinue the phrase and use in its stead "cheap metal." Gradually, however, custom became too strong for him, and he had had to revert to "base metal" because everybody else used it. He was indebted to Dr. Harker for his remarks about the magnesia tubes. Very frequently one thought a thing was going to turn out very good, and then one found some little defect which had not been anticipated, and it did not come up to expectations. He did hope, even if magnesia was not a satisfactory sheath, somebody at some time would devise a good non-permeable sheath for pyrometers which would stand a temperature in the neighbourhood of 2000° C. Speaking within practical limits, the more fragile the pyrometer, and the less material there was about it, the more accurate it was likely to be, but then there were mechanical limitations which had to be provided for There was no doubt that some of the pyrometers in use were absurdly strong—far stronger than was necessary, and the strength was put in at the expense of accuracy. With regard to the carbon graphite junctions, one point in their favour was that artificial graphite could now be obtained of any required size. There were rods on the table in front of him which illustrated that. Finally, he would like to make one more remark with regard to the possibility of a liquid element in a resistance pyrometer. Dr. Northrup conducted his measurement on the resistance of molten metals by having molybdenum terminals dipped in copper. In the work that gentleman carried out, the liquid was between two of those molybdenum terminals, and the results were of a very good order of accuracy, to some fraction of 1 per cent. But whether a practical liquid element could be made out for a furnace was a matter which, for the present at any rate, he preferred to leave to the instrument-maker.

On the motion of the Chairman a vote of thanks was accorded to the author for his interesting and instructive paper.

SUBMARINE SIGNALLING.

A recent number of *Engineering* (April 16th) contains an interesting article on recent advances in submarine signalling, founded on two papers read by Mr. J. B. Millet and by Commander F. L. Sawyer before the Society of Naval Architects and Marine Engineers at the New York meeting last December. It will be remembered that Mr. Millet introduced the invention to this country in the paper which he read here in May, 1906.*

According to the writer in *Engineering*, the whole recent development has been in the direction of furnishing ships with warning signals from coast bells, and little practical advance has been made in the way of fitting ships with means of signalling from one vessel to another in a fog. It appears that this extension of a very valuable invention has not as yet passed beyond the experimental stage.

Apparatus has, however, been constructed, and a brief description of it will be found in *Engineering*, by which ships approaching one another at full speed have been able to locate one another's position at distances of from two to three miles, while distinct signals have been received over a distance as great as ten nautical miles. It is suggested that by one or other of the systems described—one of which is the invention of Professor Fessenden, and the other of Mr. H. Christian Berger—a submarine could be fitted up so that she would be able, by means of a comparison of the sounds heard in two sensitive receivers, one on each side, to stalk a moving battleship, and with practice to ascertain her position with fair accuracy. In the same way a destroyer might discover and stalk a submarine. These, however, appear to be matters for further investigation and future development.

BUNDER ABBAS AND ITS TRADE.

The future of Bunder Abbas, one of the chief ports of the Persian Gulf, is very interesting, especially in view of the prospective development of Basra through the transfer of the vilayet and city of that still more important emporium and locality from Turkey to Great Britain. Bunder Abbas consists of a straggling collection of houses built of sun-dried bricks, which stretches along the beach for about a mile and a half, and gives access to the various routes to the interior. These routes give the town its real importance, and thereon its prosperity and trade very largely depend. Only a very small proportion of the goods landed at Bunder Abbas is consumed in the place itself; the bulk is forwarded to Yezd, Kerman, and other distributing centres in the interior, the port being thus the gate of South-Eastern Persia through which goods pass on their way to and from the interior. The official language is Persian, and the better

* See *Journal*, May 4th, 1906, Vol. LIV. p. 642.

classes can all speak and write it correctly. It is also interesting to know that there is an increasing tendency to learn English, and instruction in our language is now given in the local school by a native of India. Many of the rising generation, therefore, should possess a practical knowledge of English in a few years' time. The roadstead is an open one and very shallow, but, on account of the islands in front, is very sheltered. Port in the European acceptation of the word there is none; there are neither wharves nor lights, and, owing to the shallowness of the water, ships have to anchor about one and a half to two miles out. Goods, having been lightered —a process which is very laborious—and passed through the customs, have to be sent by the consignee to the interior, the means of transport being camels, donkeys, and mules, the last being scarce and expensive. Kerman is the chief centre to which goods are sent, and for camels the journey takes thirty-five days. The roads are extremely rough, but during 1913–14 their condition has shown a marked improvement, and only one minor robbery has been reported. The trade is extremely responsive to any improvement in the condition of the trade routes and cheaper telegraphic communication, and there seems every likelihood of a greater volume of trade next year. Sugar and piece goods comprise 63 per cent. of the total imports. During 1913–14 imports of German beer largely exceeded those of British beer, but the year just passed will doubtless have shown a reversed condition of affairs. With regard to cotton piece goods, those imported from India seem to be steadily gaining in popularity at the expense of those from the United Kingdom. Carpets form 53 per cent. of the total exports, and show a steady increase. The manufacture of carpets is the sole industry in these parts, and it is difficult to imagine a better means of payment for goods imported from abroad in the case of a country possessing no means of transport except beasts of burden.

EMPIRE NOTES.

Australian Transcontinental Railway Extension.—The Prime Minister of Australia, recognising the need for a strategic transcontinental railway, as suggested by Lord Kitchener during his visit to Australia a few years ago, is anxious that there should be a cross-country continuation of the line now being constructed between Kalgoorlie (Western Australia) and Port Augusta (South Australia), in order to avoid the risks attending the use of the present trunk lines, which are often close to the coast. In the course of a statement on the subject, Mr. Fisher laid great stress upon the time-saving possibilities of the proposed extension, which would run from Port Augusta to Brisbane through South Australia to the Murray Valley, then between the Darling and the Lachlan Rivers in a north-easterly direction to the neighbourhood of the Moree in New South Wales. Some striking alterations in the distances between the various State capitals, said Mr. Fisher, would result from the construction of the railway. On the completion of the Kalgoorlie to Port Augusta section of the transcontinental railway, Perth would be connected by an almost straight line through to Sydney, the existing railway between Condobolin and Sydney being probably made part of the route. Melbourne also could be brought into much closer touch with Brisbane. It is estimated that with through railway communication between Brisbane and Perth the journey could be made in sixty hours less than by the completed inter-State system, at present being constructed, while the reduction of time between Sydney and Perth would be about forty hours, and between Adelaide and Brisbane by something like thirty hours. Figures like these, said Mr. Fisher, appealed strongly to the military authorities, who were looking at the question from the point of view of defence; but the commercial community all over the Commonwealth would be interested quite as much in any practicable scheme which would bring the capitals closer together. A preliminary survey is being arranged of the proposed route from Port Augusta to Brisbane as outlined by the Prime Minister. The estimated cost of the extension would be about £6,000,000.

Railway Development in British Columbia.—According to Sir Richard McBride, the Premier of British Columbia, who is at present on a visit to this country, railway development, notwithstanding the financial stringency of the times, has been progressing at a splendid rate in that province. Within the past year the Grand Trunk Pacific Railway has completed its transcontinental line to Prince Rupert, and has now opened a through service between that point and Winnipeg. The region traversed by that system in British Columbia was some 600 miles to the north of the section through which the Canadian Pacific Railway passed. In the south, the Canadian Northern line had completed its transcontinental section to tidewater on the Pacific coast, and by midsummer a through service would be inaugurated. This would not only give the province a third transcontinental service, but would also place British Columbia in close touch with many towns on the Canadian Northern system, which would become purchasers of the fruit, timber, and fish produced by the coast province. On Vancouver Island the Canadian Northern has proceeded well with the work of construction between Patricia Bay and Alberni, and negotiations are now in progress between the Government and the company, in order that a train service may

be inaugurated in the near future. The principal lines undertaken by the Canadian Pacific Railway were the Kootenay Central, linking up the main line at Golden with the Crow's Nest route near Steele, traversing the splendid Kootenay and Columbia Valleys, and the Kettle Valley Railway from Midway to Hope, which would practically give the Canadian Pacific a second transcontinental line to tide-water, in addition to opening up the Nicola, Okanagan and Boundary districts. In regard to the Pacific Great Eastern Railway, it was hoped that by the end of the year connection would be made between Fort George on the Grand Trunk Pacific main line and Vancouver. An extension of this line in a northerly direction from Fort George to the Peace River was projected, which would bring that important district within 800 miles by rail of Vancouver. From the Peace River, through Northern British Columbia, the Yukon and Alaska, another link of 1,200 miles would give direct railway communication between the Northern Pacific country and the entire south. Although the proposal that the United States and Canadian Governments should co-operate to push forward this project had been temporarily shelved, Sir Richard hoped that the scheme would be taken up in the near future and pushed to completion, by which fresh and profitable opportunities would be given to hundreds of thousands of enterprising people to make new settlements.

Lake Steamers for the Atlantic Trade.—In order to cope with the enormous amount of tonnage to be handled from Canadian ports this spring, it is reported that twenty-six lake boats have been chartered for Atlantic and Gulf of St. Lawrence business. For the most part, these vessels are being chartered on time charters, that is, for a period of six or seven months, so that they may return, in many cases, in time to handle the anticipated record wheat crop in the autumn. Some of the vessels, however, have been chartered with an option on their services for a year. The need of this arrangement is evident from the fact that, in addition to the usual ocean traffic, including wheat, dairy products, and manufactured goods, there will be large consignments to the War Office. The chief consignments of this kind will consist of shrapnel shell and other munitions now being made in Canada for the British Government. Grain is, however, expected to move out in heavy volume in the first six or seven weeks of navigation. The ocean rates seem to be advancing every day, according to the statement of a high official in one of the leading transportation companies at Halifax, Nova Scotia, and the owners of some ships are holding out for still higher prices. But, without the ocean business, it is affirmed, the outlook for the navigation companies would not be of the brightest as, apart from the grain to be moved from the head of the lakes immediately after the opening of navigation, the demand for inland tonnage has, so far, not been of a record-breaking character.

Flax Prospects in Canada.—The announcement of the formation of a Canadian Flax Association is of particular interest just now, when supplies of flax have been practically cut off owing to the war. There seems to be no doubt that Canada should be able to meet the demand which is sure to arise in linen centres for high-grade fibre, owing to the threatened scarcity. The climatic conditions of the soil of the Western Provinces of the Dominion are ideal for the growing of the plant, from the fibre of which the world's linen is made. At present, something like one million tons of flax straw are burnt in Canada every year, simply because it has not been raised in marketable form. In 1913, the area in flax in the west amounted to one and a half million acres, and it is estimated that, under careful cultivation, this could be made to yield at least two million tons of fine flax straw. Experts appointed by the Dominion Government, and others who have investigated the conditions of the west, agree that there is much land open for homesteading, along the line of the Canadian Northern Railway, which is ideal for flax-growing, and that there is no reason why the finest flax straw in the world should not be raised in these districts. Proper methods would, of course, have to be adopted; but these would not necessitate any disorganisation of present farming operations. It could not be expected that the finest material could be raised the first year; but, apart from the fact that the flax seed would yield sufficient to put the homesteader on his feet, there is an important advantage to be gained in planting flax the first year, as it is one of the best crops for breaking up the soil and for freeing certain natural fertilisers that are latent in virgin soil, which may be too rich at first to grow wheat to advantage.

Khaki Dyewoods from the West Indies and South Africa.—Recognising the urgency of the need of increasing the supply of yellow dyes for the manufacture of khaki cloth, the directors of the Imperial Institute have been in communication with Jamaica, British Honduras, and South Africa, for the obtaining of substitutes, obtainable from a tree indigenous to Jamaica and British Honduras, and from Cape boxwood. When war broke out, as the circular of the West India Committee showed, there was only a small quantity of cut wood available in the West Indies to meet British demands, as most of the regular supplies were destined for France and the United States. But measures

have now been adopted by the Government of Jamaica to increase purchases from the growers and to stimulate further supplies by bearing the cost of shipment to Kingston. Similar action is being taken in British Honduras, and there is every probability that the largely enhanced quantities thus obtainable will not only benefit the local growers but will also provide the British dyers with the ingredients for their industry, the lack of which, since the outbreak of the war, has been the occasion of considerable anxiety. On the advice of the Institute, trial shipments of boxwood are also being sent from the Cape, to be placed on the London market.

Lahore's Memorial to King Edward.—A memorial to the late King Edward is to be erected in Lahore at a cost of £213,345. It will consist of: (A) A medical college with (1) a new main block with administrative offices, common rooms, library and examination hall, and lecture theatres for senior subjects; (2) a research institute housing the pathology, physiology, and hygiene departments of the college; (3) a cold storage block with judicial and pathological post-mortem theatres; (4) extension of the anatomy and materia medica blocks; (5) a students' hostel to accommodate 150 students. (B) A hospital with (1) a greatly enlarged Mayo Hospital main block, of which the present medical college will form the out-patient department; (2) a much extended septic block; (3) a new tuberculosis block; (4) the conversion of the Lady Lyall Home into an eye, ear, and throat out-patient department; (5) substantial additions to the Albert Victor Hospital; (6) Indian family and private paying wards with their own operating theatre; (7) a new nurses' home; (8) residential quarters for both European and Indian house surgeons; (9) a steam laundry and disinfecting plant and incinerator; (10) a large number of menials' quarters. It is hoped that the new buildings will be completed some time in 1917.

OBITUARY.

George Humphreys-Davies.—Mr. George Humphreys-Davies died at his residence in London on April 15th, after a long illness.

Born in 1848, he practised in London since 1887 as an architect, surveyor and valuer, and he was the founder of the firm of Humphreys-Davies & Co. He was well known throughout the country as one of the leading experts in the valuation of special properties and undertakings, and particularly in connection with the exemption of machinery from rating.

Mr. Humphreys-Davies was joint-author with the late Sir Edward Boyle, Bt., K.C., of "The Principles of Rating," on a third edition of which Mr. Humphreys-Davies had begun to work. He was also the author of many papers read before various technical societies. Among these may be mentioned the "Rating of Coal Mines," read before the Institute of Mining Engineers, and the "Value of Buildings and Machinery as a Lender's Security," read before the Institute of Bankers.

He took a keen interest in social problems, especially those affecting the working-classes. He was the honorary surveyor, and often gave advice to the London Association for the Blind. He devoted much time and thought to lectures, which he gave over a long period to the members of the Plaistow Brotherhood. He was also a Freemason, holding the rank of Grand Officer in his own province of South Wales. He was a devotee of yachting, and a keen collector of china and pictures. A loyal Churchman, he liberally assisted many works of charity, the most remarkable of all his actions being the generosity with which he treated his employees, practically handing over to them his whole business, "in consideration of their long and faithful service."

Mr. Humphreys-Davies joined the Royal Society of Arts in 1908. He was also a member of the Royal Institution, the Royal Society of Literature, Ethological Society, and many other organisations.

Henry Burdett Hederstedt, M.Inst C.E.—Mr. Henry Burdett Hederstedt, whose death took place on April 29th, at his residence, Twyford Lodge, Bickley, Kent, was in his eighty-second year, having been born at Southampton in 1833.

Under his brother-in-law, the late Sir Rowland Macdonald Stephenson, he was sent out to Asiatic Turkey to conduct surveys for proposed railways. He then joined the staff on the construction of the Madras Railways, and afterwards became Chief Engineer of the Oudh and Rohilcund Railway, a position which he filled for about twenty years. He carried out many important works in India, the chief of which was the great Dufferin Bridge over the Ganges at Benares, whereby the Oudh and Rohilcund Railway was connected with the East Indian Railway.

Mr. Hederstedt had been a member of the Royal Society of Arts since 1890.

José Custodio Fernandes do Nascimento.—The Society has lost its oldest member in South America by the death of Dr. J. C. F. do Nascimento, who died in Rio de Janeiro on March 28th. He had been a member of the Society for just fifty years, having been elected in 1865.

Dr. do Nascimento was born at Pernambuco, Brazil, in 1843. He was educated in London, where he studied mechanical engineering. In 1865 he returned to Brazil, and devoted himself to the task of developing the navigation on the River Amazon, designing the first screw-propelled vessel that plied on its waters. He became one of the directors of the large shipbuilding works in Rio

de Janeiro, where many large ships have been repaired, and where others would have been built had not the troubled political state of the country interfered with this industry. Subsequently he was also a director of the repairing shops of the Central Brazil Railway, the most important line in the country.

GENERAL NOTES.

EFFECT OF THE WAR ON THE FOREIGN TRADE OF FRANCE.—The effect of the war on the foreign trade of France is clearly shown by the following statistics lately published by the Minister of Finance. They give the values of the imports and exports of that country during the last five months of last year as compared with the similar period of 1913:—

IMPORTS.

Year.	Francs.	£ Sterling.
1913 . .	3,510,432,000	140,417,280
1914 . .	1,385,274,000	55,410,960
Difference	2,125,158,000	85,006,320

EXPORTS.

Year	Francs.	£ Sterling.
1913 . .	2,969,434,000	118,777,360
1914 . .	994,624,000	39,784,960
Difference	1,974,810,000	78,992,400

This shows a decrease during the first five months of hostilities of:—

Imports— Francs. £
2,125,158,000 (85,006,320) = 59·5 per cent.
Exports—
1,974,810,000 (78,992,400) = 66·5 „

Total . 4,099,968,000 (163,998,720) = 63·2 per cent. on the total foreign trade for the first five months after the outbreak of hostilities.

KELP INDUSTRY IN SCOTLAND.—A leaflet issued by the Board of Agriculture for Scotland says the kelp industry has improved in the last five years, and it would pay crofters and others in districts where the right kind of seaweed is found on the shore. Up to about seventy years ago kelp was made for the soda which was obtained from it. Other and cheaper ways of getting soda were found out, and the price of kelp became lower and lower, so that in many districts the people gave up the making of it. Soon afterwards iodine and potassium begun to be extracted from kelp, and the price rose slightly. There were ups and downs, but, on the whole, the value increased. From 1907 to the early part of 1914 this rise in value became marked. Potash has been obtained almost altogether from Germany, where there are mines of it. Consequently, as long as the war lasts, the only important available source of potash will be kelp, and hence the price of kelp has increased since the war. The consumption of potash is very great. It is the main constituent of several important artificial manures, besides being largely used in manufactures. Also, since iodine is in growing demand in military surgery, its value, too, is likely to become higher; though even during the war the increase is not likely to be so great as in the case of potash, because iodine is obtained from the nitrate fields in Chile as well as from kelp. At the lower value of kelp before the war a crofter in the Hebrides with a horse and cart might expect to get 10s. a day for a full day's work. Often members of the same family work together. Thus a father and two sons in one summer made £30 during the time when they had no work to do on the croft. Just before the war it may be estimated that where the proprietors offered facilities on moderate terms the price which the workers might expect to receive for one ton of kelp was £5 to £5 10s. It is probable that this season at least £1 more per ton may be obtained. To secure this sum the worker will have to gather the proper weed, to dry it, and then burn it. It requires about five tons of dry weed to make one ton of kelp.

THE LABOUR MARKET IN MARCH.—According to a report in the *Board of Trade Labour Gazette* for April, employment in March showed a general improvement, and there was a shortage of male labour in many industries, especially in engineering and shipbuilding, coal-mining and agriculture, and of female labour in some branches of the clothing trade. The trades affected by war contracts continued to be very busy. There was a further improvement in the iron and steel, cotton, linen, jute, lace, silk, bleaching and dyeing, food preparation and pottery trades. There was also some improvement in the furnishing and woodworking trades, and a seasonal advance in the building and brickmaking industries The coal-mining, pig iron, tinplate, and glass trades showed little change. Compared with a year ago, there was a great improvement in all trades affected by war contracts, especially the engineering, shipbuilding, woollen, hosiery, boot, and men's clothing trades. Employment also improved in the iron and steel, building, and woodworking trades. On the other hand, the tinplate, cotton, linen, lace, silk, bleaching and dyeing, pottery, brick and glass trades were considerably below the level of March 1914. The number of days worked by the collieries was about the same as a year ago, but the number of men employed was greatly reduced by enlistments.

THE MADRAS COTTON CROP, 1914-15.—The actual area sown with cotton in the Madras Presidency is 2,355,500 acres, which is 13 per cent. less than last year, but is about 3½ per cent. above the average of the actual areas of the last five years. The area is slightly in deficit in all tracts but chiefly in

"Salems," where the season at sowing time was not favourable. In Tinnevelly, which is always the area last sown in Madras, there were indications at first that the fall in prices of cotton might result in restricted sowings, but especially in the south the rain was so heavy that cumbu failed, and late cotton was sown in its place. Sowings continued even till the end of December, and the final result is that the area sown is very little below the normal. The estimated outturn in the Presidency is 320,365 bales of 400 lbs. each, which exceeds the reported estimated outturn according to the final accounts of last year. There is, however, reason to believe that the reported outturn on the final season and crop report figures for last year was too low. Reports show that the outturn of "Cocanadas" will be up to a normal crop, and those of "Northerns" in Kurnool nearly so. The area under "Westerns" in Bellary and Anantpur has, however, suffered from prolonged drought, and the outturn there will be from 40 per cent. to 50 per cent. in deficit of a normal crop. In "Salems," the outturn in the area sown is expected to be better than last year. In "Tinnevellies" sowings were so late that it is more than usually dangerous to attempt any prophecy, but the crops, though sown late, have on the whole made good progress; and it would seem reasonable to expect there a crop of good quality, but in the extreme south with outturn below the average. The Native States of Banganapalle and Pudukkottai report an area of 28,300 acres, with an estimated outturn of 5,277 bales, bringing the gross total of the Presidency up to 323,642 bales of 400 lbs. each.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 17. ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. D. Sommerville, "Foodstuffs." (Lecture IV.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. Professor A. R. S. Kennedy, "Weights and Measures of the Hebrews."

Geographical Society, Burlington-gardens, W., 3 p.m. Anniversary Meeting.

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. H. V. Lanchester, "The Evolution of the Architectural Competition."

TUESDAY, MAY 18 ... Statistical Society, Adelphi-terrace, W.C., 5.15 p.m. Mr. S. Rosenbaum, "The Effects of the War on the Overseas Trade of the United Kingdom."

British Constitution Association, at THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 10.30 a.m. (Annual Conference.) 1. Presidential Address. 2. M. Yves Guyot, "Economic Lessons of the War."

2 p.m. Sir W. Ramsay, "Lessons of the War—What we have to Learn."

Illuminating Engineering Society, at THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m. 1. Annual General Meeting. 2. Discussion on "Some Points in Connection with the Lighting of Rifle Ranges."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. Soddy, "Advances in the Study of Radio-Active Bodies." (Lecture II.)

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Dr. J. O. Kinnaman, "Who were the Cliff-Dwellers?"

WEDNESDAY, MAY 19...Meteorological Society, 70, Victoria-street, S.W., 4.30 p.m. 1. Dr. H. R. Mill and Mr. H. E. Carter, "The Wet English Winter of 1914-1915." 2. Mr. J. E. Clark, "Report on the Phenological Observations for 1914."

British Constitution Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 11 a.m. (Conference continued.) Dr. T. Baty, "The War and International Law."

2. p.m. The President, "The Meaning of Nationality."

Microscopical Society, 20, Hanover-square, W., 8 p.m. Dr. M. Burr, "On the Male Genital Armature of the Dermaptera."

Literature, Royal Society of, 20, Hanover-square, W., 5.15 p.m. Professor W. L. Courtney, "Marlowe and Shakespeare."

THURSDAY, MAY 20...Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.30 p.m. (Wilbur Wright Memorial Lecture.) Professor G. H. Bryan, "The Rigid Dynamics of Circling Flight."

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Chemical Society, Burlington House, W., 8.30 p.m. 1. Mr. P. W. Robertson, "A new method of estimating bromine and chlorine in organic compounds." 2. Mr. B. Campbell, "Contributions to the study of acenaphthylene and its derivatives."

Royal Institution, Albemarle-street, W., 3 p.m. Professor V. H. Blackman, "The Movements and Activities of Plants." (Lecture II.)

Historical Society, 22, Russell-square, W.C., 5 p.m. Rev. P. H. Ditchfield, "The Errors of Macaulay in his Estimation of the Squires and Parsons of the Seventeenth Century."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. E. A. W. Phillips, "Lime Concrete in the East."

Royal Society of Medicine, 1, Wimpole-street, W., 4.30 p.m. Section of Dermatology.

5 p.m. (Annual Meeting.) Discussion on "The Pemphigoid Eruptions," to be opened by Dr. J. M. H. MacLeod.

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 8 p.m.

FRIDAY, MAY 21...Royal Institution, Albemarle-street, W., 9 p.m. Mr. E. H. Allen, "Beauty, Design, and Purpose in the Foraminifera."

Royal Historical Society, 22, Russell-square, W.C., 8.30 p.m. The Hon. J. W. Fortescue, "The Last Great War (1795-1814) and the Present."

SATURDAY, MAY 22...Royal Institution, Albemarle-street, W., 3 p.m. Dr. M. O. Forster, "Colouring Matters of the Organic World." (Lecture I.)

Journals Wanted.—One of the departments of University College, London, is anxious to be supplied with a second copy of the Society's *Journal*, in addition to the copy presented by the Society to the College Library. Any Fellow who does not preserve his *Journal*, and would therefore be willing to give it away after he has done with it, would confer a favour on the Secretary of the Society if he would communicate with him. A gift of any fairly complete sets of the *Journal* for the past two years would also be appreciated.

Journal of the Royal Society of Arts.

No. 3,261. VOL. LXIII.

FRIDAY, MAY 21, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

THE SOCIETY'S ALBERT MEDAL.

The Albert Medal of the Society for the current year has been awarded by the Council, with the approval of the President, H.R.H. the Duke of Connaught and Strathearn, K.G., to Professor Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S., for his researches in physics and chemistry, and their application to the advancement of Arts, Manufactures, and Commerce.

CANTOR LECTURES.

On Monday evening, May 17th, Dr. David Sommerville, B.A., M.Sc., M.R.C.P., D.P.H., Assistant Professor of Hygiene and Public Health, University of London, King's College, delivered the fourth and final lecture of his course on "Foodstuffs."

On the motion of the Chairman, a vote of thanks was accorded to Dr. Sommerville for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, May 4th, 1915; The Hon. Sir George Perley, K.C.M.G., member of the Canadian Government, in the chair.

The Chairman, in opening the meeting, desired in the first place to say how happy he was to take the chair at a meeting of the old and influential Royal Society of Arts. It was an honour and a privilege which he much appreciated, not only personally but because it was an honour to Canada, which he represented in London. The author of the paper to be read at the meeting was the founder and proprietor of *The Paper Maker*, and had long been a well-known figure in paper and pulp trade circles, not only in this country but on the Continent and across the Atlantic. For the past thirty years he had devoted most of his time to investigating paper-making and allied subjects, of which raw materials formed a very important part. The author had visited every country in the world where paper-making was carried on; he had been in Canada and the United States many times, and had travelled to every territory where raw materials for the industry were found to investigate the possibility and the use of new fibres for paper-making. The author had taken great personal interest in all practical ideas relating to the discovery of new fibres, and had spent a great deal of time in investigating the claims of the various materials brought to his notice. He was therefore specially well informed about the subject on which he was to read the paper. Ten years ago the author read a paper before the Society on the use of wood pulp for paper-making, on which occasion the late Lord Strathcona presided. He (the Chairman) desired to take the present opportunity of saying how much they missed Lord Strathcona and his wise counsel, which was at the service of Canada for so many years, and which was needed so much during the present critical times.

The paper read was—

THE EMPIRE'S RESOURCES IN PAPER-MAKING MATERIALS.

By S. Chas. Phillips, M.S.C.I.

It may be within your knowledge that in the year 1905 I had the honour of presenting in this room a paper on "The Use of Wood Pulp for Paper-Making." That paper was devoted exclusively to wood pulp considered particularly from the paper-makers' point of view, and on that occasion we were honoured by the presence in the chair of the late Lord Strathcona who, I happen to know, took a very close personal interest in the wonderful possibilities of Canada as a field for the paper-makers' enterprise. It is, I venture to say, extremely fitting

also that Sir George Perley is with us this afternoon, because he has also proved in many ways that he fully realises how the present and future interests of Canada are largely bound up with paper-making and paper-makers' requirements, and it is a very interesting fact that in the consideration of "The Empire's Resources in Paper-Making Materials" Canada stands out almost by itself.

I have taken a very close interest in this wide subject during the past thirty years and have travelled frequently and extensively in many countries, including many parts of the British Empire in connection with my studies of wood and other fibres suitable for paper-making purposes. In fact, I have devoted the major portion of my life in all parts of the world in investigating the many processes employed in connection with my text and watching their development.

I need scarcely tell you that cheap papers are now produced mainly from wood pulp, and, although we in this country are still dependent to a large extent on Scandinavia for our supplies, Canada as a wood pulp country has come to the front with great rapidity. It is very gratifying to know that Canada at the present time supplies the world with 320,000 tons, approximately, of paper-making materials in the shape of wood or wood pulp, chemical or mechanical.

It is no secret that America in recent years has been turning, I am tempted to say, with a feeling almost approaching anxiety, to Canada for wood pulp for the purposes of paper-making, and, to the uninitiated, it is almost startling to know that one undertaking in the Province of Quebec has a capacity for sending out, roughly, 100,000 tons of ground wood per annum, a very considerable proportion of which is consumed in England, very largely by paper-mills on the Thames.

Time does not permit of my going into very precise details as to the materials used in a modern paper-mill, but although the paper-maker to-day relies chiefly on rags, wood, or esparto, it may be necessary to refer in a general way to quite a number of other fibres which have been in years gone by, and are even to-day being experimented upon with more or less success. For the purpose of this paper we may consider rags, wood, bamboo, and, to a limited extent, other fibres, also peat, as covering for practical purposes the materials utilised to-day and produced within the Empire on a commercial basis for paper-making.

I may also say that this paper has not been prepared for the purpose of educating the paper-maker, neither do I claim to be able to teach some of the gentlemen I see present anything regarding what I may term the higher botany. I am merely endeavouring to collate certain facts, which, I hope, may be helpful to those who are seriously considering the application of certain possible fibres which may be of practical service to paper-makers in the future.

I strongly advise any one interested in this subject to pay a visit to the Museum at the Royal Botanic Gardens, Kew; and I may here say that by the kind courtesy of Mr. J. Masters Hillier, Keeper of Museums, I was recently permitted to inspect and examine the extremely interesting specimens of direct interest to paper-makers there to be found. Like most people who have gone pretty deeply into the subject of the consideration of fibres suitable for paper-making, I have found that many of the so-called new fibres have been experimented upon again and again, and many of the old reports dealing in detail with investigations of half a century ago, and even prior to that date, deal specifically with kindred fibres which are constantly cropping up, and even to-day are being in certain quarters considered and investigated as novelties. Another important fact which should not be lost sight of is quite common in the experience of investigators—that of jumping to the conclusion that certain fibres, which in handling and appearance have a close resemblance, may be of equal utility when submitted for practical purposes to the paper-maker. Investigations show that, as a matter of fact, many of these growths, apparently so much alike, are totally dissimilar in regard to yield and paper-making qualities. Mr. Hillier incidentally mentioned that this experience is not confined to paper-making and paper-making fibres, but is pretty general in regard to other trades where enterprising people are constantly on the look out for new fibres of practical utility. The Museum at Kew devoted to economic botany affords convincing evidence of the amount of research devoted to the subject now under consideration in bygone years, and the name of Mr. Routledge is constantly recurring, and most of us, I think, will agree that it was largely due to Mr. Routledge's experiments and persistency that we to-day, as paper-makers, hold the strong position we do in esparto papers.

Mr. Routledge satisfied himself that the true esparto had many advantages over its so-called rivals, but with the loyal co-operation of the

then Director of the Gardens at Kew, and other gentlemen whose help was invaluable, Mr. Routledge investigated the properties from the paper-makers' standpoint of quite a number of samples, which included bamboo, baobab, etc.

In regard to baobab, Professor Hübner, in the year 1903, in his Cantor Lectures, had many interesting things to say; and Mr. Routledge appears to have made exhaustive experiments with baobab (otherwise maputa cloth), which it has been found is capable of yielding paper very much after the style of what we know as Japanese papers, producing a number of specimens which he described as "fair paper." He also investigated and experimented with heliconia, bihai, *Lepidosperma gladiatum*, which it was found did not offer much promise; also *Phragmites communis*, the well-known British reed which at one time was described as affording great possibilities, which, however, were not realised.

Then tests were made with majorca and *Uniola virgata*, which fibre was described as possibly one which might, if necessity arose, be "something to fall back upon," and, although not as good as esparto, either in yield or quality, was useful.

In the years 1876–7 Dr. King, Superintendent of the Royal Botanic Gardens in Calcutta, supervised a large number of experiments which covered a very large field, and, briefly, his findings were that the Californian cactus gave indifferent results. The *Calotropis gigantea* provided two fibres, one of which was considered likely to be of value to paper-makers, but actual tests did not apparently come up to expectation. Caraguata was also examined without very definite results, but a particularly interesting fibre was the *Cavanillesia platinifolia*, a growth allied to the mallow. The examiners reported regarding this: "It pulps extremely well and bleaches readily, and is capable of being made into strong opaque white paper of fine quality."

Opontia, a kind of prickly pear, seems to have occupied a lot of attention at one time, but was found to be of no economical value.

In the year 1878, the Rev. C. Parish wrote a number of contributions as to the possibilities of bamboo; and he considered that one of the principal virtues of bamboo, from the paper-makers' standpoint, was its rapid growth, and the fact that it could be cut annually. Thus does history repeat itself.

A particularly interesting fibre is that of *Broussonetia papyrifera*, of the mulberry tree order, which, incidentally, provides the famous tapa cloth, a cloth that serves a large variety of purposes in the countries where it is grown. Mr. Routledge was very enthusiastic regarding what we may describe as the tapa cloth fibre, and he reported upon it that "it is nearly, if not quite, the best fibre I have ever seen, and I must admit it is even superior to bamboo. It requires very little in the way of chemical treatment, and gives the excellent yield of 62·5 per cent. in the grey, *i.e.*, merely boiled, condition, and 58 per cent. bleached."

Very encouraging results were at one time obtained from the guadua (gigantic bamboo), and considerable attention has also been devoted to *Molinia cœrulea*, otherwise rye straw; and in the year 1880 a report was presented to the India Office on the commercial value of muddar. Probably many present are aware, also, that the report of L. Liotard provides a most valuable contribution regarding the materials in India suitable for the production of paper. This report is very exhaustive, and, if time permitted, I would like to have presented some of the very interesting details given in L. Liotard's publication. The investigators seem to agree that none of the fibres experimented upon appear to compete seriously with esparto, particularly as regards supplying British paper-makers, for reasons well understood.

I may here mention that, at this moment, one of our leading paper-making experts is making experiments with the *Nipa fruticans*, otherwise known as the nipa palm, and I have here some laboratory-made specimens, made in London, from this fibre quite recently. Some of the specimens, of what may be described as fibre boards in a very rough and unfinished condition, are distinctly good in the essential properties of value in boards of this class; and possibly we may hear more of the nipa palm, providing it can be collected and partly prepared in countries where it abounds, and can be delivered in Europe in quantities and of a quality makers of strong boards and strong packing papers might seriously entertain.

Whilst at the Museum at Kew, I learned the extremely interesting fact that nuts of the *Nipa fruticans*, and of allied plants, have been found in considerable quantities in the tertiary remains unearthed from time to time in the Isle of Sheppey, at the mouth of the Thames. That this plant should have grown here at some very remote period provides food for thought and reflection.

A special article could be devoted to lallang grasses alone (*Imperata arundinacea*), which one

authority described as a pestilent weed which, when once allowed to invade a plantation, can only be eradicated at enormous expense. These grasses have been very closely and adequately experimented upon at the Aynsome Laboratories, and Messrs. John Dickinson and Company made experiments on them in the year 1905; but apparently had only an opportunity of testing a block of dried fibre, which gave results intermediate between Spanish esparto and good straw fibre.

Great Britain.

This country is not rich in paper-making fibres, but it is interesting to recall that two or three years ago attention was drawn to the possibilities of marram (or beach) grass (*Ammophila arenaria*), which is grown on the sandhills around our shores, as well as on the Continent, in temperate North America, Northern Africa, and Australia. It is one of the most valuable of the grasses adapted to binding drifting sands; but, according to Spon, its fibre is used for paper-making, matting, and tie bands, and is employed as thatch material. To what extent it has ever been used in the production of paper I am not able to say; but there is the authority of Beadle and Stevens, who some time ago examined a consignment of marram grass from the Norfolk sandhills, for stating that it was found to produce "a soft pulp with a short tear, which more nearly resembles in general feel and external appearance the pulp produced from esparto or chemical aspen wood pulp." The grass was boiled under pressure, without passing through crushing rollers, and then bleached, the result being that the yield of unbleached fibres on the original green weight of the stem was 17·7 per cent., and on the dry weight 31·4 per cent., the yield of bleached fibres being 13·1 and 25 per cent. respectively. Messrs. Beadle and Stevens suggested that, should marram grass be deemed of sufficient importance as a paper-making material, its cultivation could be extended over considerable tracts of sandy country bordering the coast in various parts of the British Isles.

Quite recently serious suggestions were put forward in the House of Commons with a view to afforestation on a large and scientific scale in the United Kingdom, particularly in Scotland, and it was suggested that a great deal of timber required for paper-making in this country could be produced at home. I believe some gentlemen advocated this idea as a remedy for unemployment, but I do not think there is any likelihood of timber being grown at a profit or with any considerable success, especially for the purposes of producing pulp.

Not long ago, Mr. T. Parker Smith, the managing director of one of our leading paper-making concerns, presented an interesting paper on the subject before the British Paper-Makers' Association, and the facts and figures he presented were very interesting. Personally I do not see much prospect of timber-growing in Great Britain as a sound commercial proposition considered from the paper-makers' standpoint.

It may be within the knowledge of most of you that for a number of years past experiments have been made, with more or less success, with a view to the utilisation of peat as a raw material for paper and boards. Peat is said to be used successfully in the making of wrapping papers in America; but the experiences of paper-makers who have experimented with peat in Great Britain and Ireland have been unfortunate, and I can call to mind at least three ventures of this character which have ended disastrously for the shareholders and creditors. Numerous patents have been taken out for the utilisation of peat in paper-making, and one inventor claims that the oily bodies contained in the peat make paper impermeable to the attacks of insects, rendering furs, etc., wrapped in it safe from moths and mice.

It has been argued that as there are at least 2,800,000 acres of peat in Ireland, the beds in places being 15 ft. in depth, the making of peat paper might become an important Irish industry. Not long ago a company was formed for this particular purpose, and, so far as I am aware, it has gone out of existence. Patents have also been taken out for the forming of paper or board from half-stuff, in which peat played an important part, and in Sweden a factory has been built for the manufacture of board and so-called kraft paper from peat, although, personally, I doubt whether anything of the nature of kraft paper could successfully be made from peat. Attempts have also been made to produce blotting-paper from peat, and at one time there was an undertaking near Athy, co. Kildare, to put these ideas into operation. A well-known Lancashire paper-making firm has also devoted considerable time and trouble to discovering how far peat might be successfully used as loading material in brown papers of various kinds, but these attempts have only met with qualified success.

It has been stated by an authority that peat

is in appearance very misleading, not only to the eye of the layman, but also to the expert, and that peat is generally found intermixed with numerous other fibres and a good proportion of undesirable matter, and it has been computed that 100 tons of bog land might yield 8 tons of solid matter, and that this 8 tons of solid matter would contain at the most 2 tons of peat fibre. The waste involved directly and indirectly has proved a terrible disappointment to those who have entered into the utilisation of peat with enthusiasm. In the year 1912 a gentleman well known in the paper trade of this country observed that the only successful employment of peat to his knowledge in the paper trade was in mills where about 5 per cent. of peat was added as a colouring agent and partly as a filler, and it does appear that there are very serious practical drawbacks in regard to the successful employment of peat for paper-making.

In Canada the Dominion Government also recently caused investigations of peat to be made, and special attention was paid to the consideration of peat as a paper-making material. It was pointed out that in the Museum of the Swedish Peat Society will be found a considerable collection of peat paper samples from different places, and these include specimens of paper and board said to have been made from Irish peat. It was eventually stated that: "Scientific men in the paper industry do not seem to have had very much confidence in the result of these experiments in regard to peat as a paper-making material, and this lack of confidence was very pointed." It may be fairly stated that the consistency of peat is such that it cannot be expected to make strong and durable paper without the employment of complicated and extensive machinery necessary for the cleaning, bleaching, and dyeing of the peat, and what is of even more importance is the fact that the finished article leaves a great deal to be desired, and can scarcely compete with other materials now on the market.

I may add that, personally, I am rather sorry to have to arrive at this conclusion, as I have purchased my experience rather dearly, and certainly some of our most eminent paper-makers and chemists have been disappointed in regard to the possibilities of peat.

Canada.

That the Dominion of Canada in its vast forest areas possesses an enormous source of wealth with potentialities which as yet are not fully realised may be gathered from the fact that the latest estimates place the total area of land covered by timber at anything between 500 and 600 million acres, of which about half are covered with timber of commercial utility. In 1912 the estimated value of Canada's forests products amounted to the enormous sum of $182,300,000, or nearly £38,000,000, and in view of the annually increasing development in the lumber and timber industries it may be safely said that to-day the figures would reach something like $200,000,000, or about £41,700,000. It is, too, encouraging to note that the Dominion and Provincial Governments, appreciating the importance and the necessity of husbanding the timber resources of Canada, have during the past fourteen years greatly increased its forest reserves, the total area of which has grown from 7,413,760 acres in 1901 to 152,833,955 acres in 1914, measures being also taken, especially by the education and training of forestry experts, to bring the forest areas of the country under more scientific and remunerative management.

Of fifteen groups of kinds of industries in Canada, that of "Timber and Lumber and Re-Manufactures" is easily first when judged by the capital invested, number of employees, and the amount of wages paid, and it is interesting to note that towards this pre-eminence the production of pulp wood for paper-making purposes largely contributes, its value so recently as 1912 being estimated at $12,000,000. Spruce is, of course, the principal wood used in the manufacture of wood pulp in Canada as elsewhere, but balsam fir is also being increasingly used; while hemlock and jack pine have latterly been employed for the same purpose though to a smaller extent. Statistics published in the "Canada Year Book for 1913" show that in that year the following quantities of spruce and other woods were used in the manufacture of pulps: Spruce, 754,858 cords of the value of $5,104,221; balsam fir, 283,292 cords ($1,806,911); hemlock, 47,360 cords ($201,480); poplar, 4,141 cords ($29,081); and jack pine, 19,383 cords ($101,675)—making a total of 1,109,034 cords of the value of $7,243,368. Of this over 600,000 cords, were converted into mechanical pulp, 367,105 cords into sulphite, 136,569 cords into sulphate, and 5,144 cords into soda pulp.

Only yesterday I was fortunate enough to receive from Mr. R. H. Campbell, through the Forestry Branch of the Office of the Commissioner of Commerce, Ottawa, a copy of the statistics for 1914. These show that the quantity of pulp

wood cut in Canada last year amounted to 1,222,527 cords, of a total value of $8,068,184. The cut of spruce was 834,538 cords, of the value of $5,584,242 ; balsam fir, 314,183 cords ($2,067,434) ; hemlock, 45,246 cords ($254,576) ; jack pine, 24,715 cords ($135,762); poplar, 3,845 cords ($21,170). Of the total cut of 1,222,527 cords 52·6 per cent. was converted into mechanical pulp, 33·1 per cent. sulphite pulp, 14 per cent. sulphate, and 0·3 soda pulp. It is noteworthy that while the cut in Quebec and Ontario has shown some increase, those in British Columbia, New Brunswick, and Nova Scotia have decreased, the figures for the five Provinces being Quebec 636,469 cords ; Ontario, 445,902 cords ; British Columbia, 80,013 cords ; New Brunswick, 49,339 cords ; Nova Scotia, 10,337 cords.

The ever-increasing drain upon the forest resources of Canada and the tremendous losses sustained by fire give rise from time to time to anxiety as to the future, but the general opinion —endorsed from time to time by public men— seems to be that the great northern forests of the Dominion are practically exhaustless, and "will afford an abundant supply of timber for all future time," which will be amply sufficient, not only to meet Canada's own needs, but also the increased demands of the United States, and afford a surplus for export to this and other countries. Some time ago, however, Dr. F. D. Adams, Dean of the Faculty of Applied Science at McGill University, in the course of an address before the Royal Society of Canada, made the following significant statement :—

"A careful study of the question by the Dominion shows that so far from being exhaustless, the reserves of merchantable soft timber in the forests of Canada are only between one-quarter and one-fifth of that remaining in the forests of the United States. Of these reserves in Canada, about one-half is in the old provinces of Eastern Canada and the other half in British Columbia. The evidence goes to show that at the present rate of cutting the supply of timber will, within a comparatively few years, be sufficient only for the needs of the Dominion itself, leaving no surplus for export.

"It must be borne in mind that, while a large part of Canada is covered with forest, much of this is a woodland country rather than a country covered with a forest which produces considerable supplies of merchantable timber. Furthermore, the practice which has been followed of cutting out the valuable kinds of timber has left the successively poorer and inferior species of trees—'tree weeds' as they have been called—to multiply without restraint, and thus the forest gradually changes its character and deteriorates in value. Moreover, the rivers draining the northern forest flow down to Hudson Bay, so that the logs if floated down the streams would reach that body of the water instead of the St. Lawrence. With the approaching exhaustion of the reserves of standing timber, there has sprung up within the past few years a demand for pulp wood, to supply which the younger and smaller trees are taken and ground up for the manufacture of paper. Fortunately this is not necessarily so fatal to the continued existence of our forests as might be supposed, for the younger trees, if properly cared for, grow in a relatively few years to the size required for pulp wood. Thus, if the limits over which a company cuts its supplies are large and properly cared for, they can be made to produce a continuous supply of wood for the pulp-mill. Our great water powers adjacent to the supply of raw material should make this pulp and paper industry a permanent source of wealth to the Dominion."

It requires some courage to calculate in figures the vast extent of Canada's pulp wood resources, and, indeed, it is somewhat difficult to frame anything like a reliable estimate in view of the facts that there is no sharp line of distinction between wood that can be used for pulp-making purposes and that which can be used for lumber, poles, etc., and that enormous areas, particularly in the northern regions of the Dominion, are either entirely unexplored or only partially explored. From data furnished about two years ago by the Canadian Forestry Department, it has, however, been estimated that the Dominion pulp wood resources approximated to 2,024,000,000 cords, on about 265,000,000 acres of land, made up as follows: Dominion lands, 100,000,000 acres; Quebec, 60,000,000 acres; Ontario, 40,000,000 acres; British Columbia, 40,000,000 acres; New Brunswick, 20,000,000 acres; and Nova Scotia, 5,000,000 acres. Of the five provinces mentioned, Quebec takes premier rank, not only in regard to pulp wood production, but also in regard to pulp wood still standing unutilised. According to a report prepared by Mr. R. G. Lewis, B.Sc.F., for the Forestry Branch of the Canadian Department of the Interior, and issued on May 25th, 1914, the statistics furnished by twenty-six firms operating thirty-four pulp-mills, showed that, in 1913, 629,934 cords of pulp wood were used,

the quantity consumed in Canadian pulp-mills giving an increase of 28·1 per cent. over that of 1912. The balance of 802,260 cords was exported.

During the last ten years much useful work has been done in survey and exploration work in the Province of Ontario under Government auspices, and some years ago a serious attempt was made in Northern Ontario to calculate the approximate pulp wood contents of each section covered by the survey parties. Referring to the territory north of the Height of Land, the report stated: "There is little pine timber, the trees being scattered and inferior in quality. Some small areas of red pine and some jack pine were met with, nearly all of these varieties found being south of Lake Abitibi. The best areas for pulp wood are on Low Buch and Circle Rivers, with their tributaries, where it is estimated that an area of 180 square miles will yield an average of seven cords to the acre, or about 800,000 cords. Along little Abitibi River, between Harris Lake and the boundary, the pulp wood is estimated at 750,000 cords. A belt reaching from Lower Abitibi Lake along the Abitibi River to Long Sault, eighty miles in length, will average seven cords to the acre. There are also considerable pulp wood areas to the west and north of Lower Abitibi Lake. District No. 2 embraces fifty miles on each side of a base line run west from the 198th mile-post on the boundary line between Nipissing and Algoma Districts to the Missinabie River, about one hundred miles, and also the tract lying southerly along the Missinabie River up to near Missinabie Lake. Of the territory explored, 60 per cent. will yield on an average five cords of spruce wood. The spruce, especially along the river banks, attains a size which renders it valuable for square timber, and the poplar is large and abundant, particularly on the Mattagami River. Special acres examined would yield twenty cords of spruce, other acres would cut fifteen cords of spruce and ten of poplar. Some of these, if all the timber growing on them were made into cord wood, would show sixty to seventy cords to the acre. Survey work along the proposed route of the Hudson Bay River indicates that there are large tracts of country containing a good percentage of wood adapted for pulp."

Again quoting from Mr. Lewis's report, it appears that in 1913 twelve firms operating seventeen pulp-mills in Ontario, used 321,244 cords of pulp wood, the remaining 84,699 cords being exported, the total production having amounted to 405,943 cords compared with 246,282 cords in 1912.

Coming to British Columbia, the same authority shows that, in 1913, 84,173 cords of pulp wood were cut as against 35,067 cords in 1912, and nearly the whole of it was manufactured into wood pulp, only sixty-nine cords being exported. This province, whose pulp wood areas have been roughly estimated at 40,000,000 acres, it is claimed, should eventually be able to furnish half the world with wood pulp, and there can be no doubt that the geographical position of the province is an extremely favourable one, her pulp wood resources being within easy reach of deep-water harbours, while the mildness of the coast climate enables working operations to be conducted practically all the year round. It may, indeed, be said that British Columbia "possesses natural resources of pulp wood and water power which are not equalled by any other province in Canada, the water power on tide-water alone being estimated to be 1,000,000 horse-power, and many billions of feet of pulp wood being tributary to this."

Another important province of the Dominion, from the pulp wood point of view, is New Brunswick, which contains large areas rich in pulp wood trees. As I have already mentioned, these have been estimated at 20,000,000 acres, the approximate production of pulp wood being calculated at 100,000,000 cords. According to the report of Mr. Lewis, the output of pulp wood in 1913 was 194,674 cords, 27·3 per cent. of which was converted into pulp and 72·7 per cent. exported.

There is still another province of the Dominion which presents an increasingly promising field for pulp wood supplies, Nova Scotia, whose pulp wood areas form no mean asset. The Agent-General for the province, Mr. John Howard, informs me that it is estimated that the forest lands of Nova Scotia contain 54,250,000 cords of pulp wood valued at £1 per cord, and I gather from the returns for 1913 that its production of pulp wood in that year amounted to 26,611 cords, of which 22·7 per cent. were exported, the remainder being consumed locally in the manufacture of pulp. There are several—seven, I believe—pulp-mills now in operation in various parts of the province, and owing to the amount of water available in the forest lands, the facilities for shipment, and the contiguity of Nova Scotia to the world's great markets, there are exceptional opportunities for the extension of the industry.

Of other parts of Canada, neither Alberta nor Saskatchewan can really be said to be rich in timber or pulp wood resources, but it is possible that in both these provinces, as also in Manitoba which now reaches to Hudson Bay, the aggregate quantity available will, in the future, reach a respectable figure. With regard to Manitoba, Mr. J. R. Dickson, of the Dominion Forestry Service, who, a few years ago, inspected the proposed route of the Hudson Bay Railway from Le Bas to the Split Lake, a distance of 250 miles, reported that there were fine species of timber of commercial value, including spruce, poplar, birch, and jack pine. The trees, he said, were short, but would be suitable for pulp wood. Mr. Dickson also made the significant statement that it was probable that "within the next quarter of a century part of the enormous energy now running free in the falls and rapids of Nelson and Grass Rivers will be harnessed to drive pulp and paper-mills."

As will be gathered from the statistics to which I have already made reference, white spruce is by far the most important of Canadian timber trees, and is most largely used in the manufacture of wood pulp either in Canada or other countries. It grows in the Dominion from Newfoundland to the Yukon, and its long, tough, and colourless fibres render it specially suitable for paper-making purposes. It is also gradually displacing white pine for what is known as dimension timber and boxes. Spruce is, indeed, used in more than a score of industries, but only in pulp manufacture is it the chief raw material. In one sense its use for pulp may, perhaps, be regarded as wasteful, seeing that, as Mr. R. C. Lewis says, balsam, fir, poplar, white birch, and jack pine can be made into pulp while they are of little value as lumber.

Balsam fir, which in Quebec Province forms from 25 to 50 per cent. of the forests, is steadily increasing in favour for pulp manufacture, and its use in 1913 was 25·5 per cent. of the whole, compared with 19 per cent. in 1912 and 17·5 per cent in 1911. For some years considerable prejudice existed against its use on account of the so-called pitch which it contains, and which injured the felts and cylinder faces upon which the pulp was rolled out. As a matter of fact, the material which gummed up the cylinder probably came from grinding balsam under conditions adapted to spruce wood, and if the logs are left lying in water over a season this drawback practically disappears. Probably more than 25 per cent. of balsam can be used in the manufacture of mechanical pulp without lowering the grade of paper, while, in the production of chemical pulp, the pitch is dissolved by the action of the acids, and any amount of balsam may be used, though in some quarters it is considered that "too much balsam gives a paper that lacks strength, snap, and character." Balsam fir also possesses the merits of readily reforesting cut-over areas and of attaining a size suitable for pulp wood in a short time. This wood is all cut from one species in Eastern Canada, is found all over Northern America, and is becoming increasingly valuable for paper-making. Over 48 per cent. of the balsam cut is employed in the manufacture of pulp wood.

The utility of hemlock for pulp-making purposes was first, I believe, demonstrated by the late Mr. Norman K. Brokaw, of the Kankanna Fibre Company, who is credited with being the first to produce sulphite pulp from it. He is stated, however, to have met with defeat when he sought to convert it into mechanical pulp. More recent experiments in the United States appear to have shown that, when in conjunction with jack pine in the proportion of 25 per cent. hemlock sulphite to 75 per cent. of jack pine mechanical pulp, a paper can be produced which compares well with standard "news" quality. Hemlock now figures third in the list of woods used in Canada for pulp-making purposes, its advance being largely due to its increased use in British Columbia. In 1911 only 1,670 cords were so used throughout Canada, but in 1913 this quantity had risen to 47,360 cords, the average value per cord being $4.25 compared with $6.76 spruce and $6.38 balsam fir. Altogether nine industries use this wood, all of which is purchased within the Maritime Provinces, the pulp industry consuming 8·3 per cent. of the total used.

The Maritime Provinces have also been the sole source of supply of wood pulp manufactured from poplar, of which, in 1913, 4,141 cords, of the value of $7.02 per cord, were used. Poplar has often been considered a non-commercial tree, but it forms a large percentage of the native forests, and is becoming more important as new uses are found for it. It is, I believe, the only wood treated by the soda process, but it is worth mentioning that the aspen variety makes a very white tenacious mechanical pulp. It is said to be easy to disintegrate, and other sorts of poplars are quite as good, but somewhat more difficult to pulp. One authority states that a ton of dry pulp can be got on the average from three tons of wood.

Another wood which is being increasingly used

in the manufacture of pulp wood is jack-pine, which, however, is seldom found clear of knots in large dimensions. In 1912 only 40 cords were treated, but the record for 1913 was 19,383 cords, of the average value of $5.25. The wood, I believe, is being used with advantage in soda and mechanical pulp-mills. The native pine is the second most important wood used in the Maritime Provinces of New Brunswick, Nova Scotia, and Prince Edward Island, being chiefly employed in building construction.

Small quantities—about 1/10 per cent.—of bass-wood and elm were converted into mechanical pulp in Ontario and used mostly for fibre wall-boards.

That the Canadian authorities are under no illusion as to the limitations of the Dominion forest resources, gigantic and wonderful as they are, is evident from the fact that they have already recognised the importance and necessity of adopting careful methods of conservation. As a matter of fact, Sir Clifford Sifton, the Chairman of the Conservation Commission held in Ottawa last January, made the significant remark that there was strong reason for the belief that the forest resources of Canada had been much over-estimated. It is, of course, not difficult to realise the enormous amount of work which has yet to be done by the Forestry Branch of the Department of the Interior before anything like a reliable estimate can be made of those resources, but sufficient appears already to have been done to show how vast they are. Another fact made clear is that there is a great need for adequate fire protection, involving the employment of a larger patrol force than has been previously practicable. The establishment of Dominion Forest Reserves is also an important feature in the policy of conservation, and in this connection it is worthy of mention that during last year (1914) areas in Manitoba, Saskatchewan, and Alberta, approximating to 17,900 square miles, have been temporarily reserved with a view of being later included in permanent forest reserves. Already in the three Prairie Provinces named the net area of forest reserves amounts to 33,225 square miles, while in British Columbia the reservation amounts to 2,749 square miles. In Ontario the present area of forest reserves and parks is 22,574 square miles.

Before leaving what I may call the Canadian section of my paper, brief reference should be made to the excellent work which is being carried out by the Forest Products Laboratories of Canada, which were established in 1913 under the jurisdiction of the Forestry Branch of the Department of the Interior. They are, of course, primarily interested in the conservation of forest resources by proper utilisation of the raw material. The experimental investigation of wood, and of the many products which can be manufactured therefrom, is one of the laboratories' most important and valuable functions, and there is every ground for hope that in the domain of pulp wood real service will be rendered.

Before passing on to the paper-making resources of other parts of the Empire, I ought to refer here to another fibre which has been the subject of some preliminary experiments. This is the common milkweed, *Asclepias syriaca*, which abounds in Canada as well as in North and South America and in the Old World. Dodge states that the only portion of the plant of which practical use can be made is the bast, which furnishes quite a fine, long and glossy fibre that is strong and durable, and which forms a good paper material. Little more than two years ago, Dr. A. C. Neish, before the New York section of the Society of Chemical Industry, describing some experiments to which the plant was submitted, said that "the woody tissue, making up about 80 per cent. of the total weight of the plant, presented the possibility of a new source of material for paper stock," which could be made into paper of good strength and appearance, and which takes dye just as well as other standard stocks. The paper made contained some natural sizing material, as the difference in the sized and unsized papers was hardly noticeable.

NEWFOUNDLAND.

The recent publication of the interim report of the Dominions Royal Commission on the natural resources of Newfoundland, supplemented by other information to which I have had access, renders my task with regard to Britain's oldest colony less difficult than it otherwise would have been. During the last ten years the island, which previously was principally famous for its fish and fogs, has been very much in the limelight by reason of the development of its enormous pulp wood areas by two important British companies—the Anglo-Newfoundland Development Co., Ltd., and the A. E. Reed. of Newfoundland, Co., Ltd.—in whose wake other British and American companies have since followed. The result of these enterprises has been to bring to Newfoundland a period of prosperity hitherto unknown

and undreamt of. In its forest areas Newfoundland undoubtedly possesses vast sources of wealth; but, from the paper-makers' point of view, it is even more important that those forest areas are so rich in woods suitable for conversion into pulp. For a good many years a lumber industry has been carried on upon a small scale, but it is to the wood pulp industry that Newfoundland is indebted for the position that it has now attained. The wooded lands of the island, exclusive of the considerable areas in Labrador, have been estimated to cover 10,000 square miles, with an average yield per acre of ten cords of pulp wood and 1,000 superficial feet of lumber, giving, as one witness before the Commission stated, a total yield of 64,000,000 cords of wood, equivalent approximately to 50,000,000 tons of wood pulp and 6,400,000,000 superficial feet of lumber.

Spruce and fir predominate in Newfoundland forests, but in some sections a considerable proportion of good pine is to be found. The forests of Labrador are stated to consist almost entirely of spruce. The suitability of Newfoundland spruce for conversion into wood pulp has now been well established; but, as in certain parts of Canada, balsam fir is being more extensively used than was at one time thought possible. Indeed, it was stated before the Commission by one witness that his firm got more than one-half of their pulp wood from balsam fir. Newfoundland, not unwisely, ordinarily prohibits the export of pulp wood, so that local manufacture may be encouraged; but is, I believe, destined to do an increasingly important trade in wood pulp and paper. During the year ended June 30th, 1913, no less than 57,500 tons of pulp and 44,400 tons of paper were exported, while the figures for the six months ended December 31st, 1913—pulp, 44,400 tons; paper, 33,700 tons—seem to indicate an enormous advance for the twelve months ended in June last. With regard to the forest areas of Labrador, it would seem that natural conditions are not favourable to anything more than a pulp wood industry being conducted, for which reason it is suggested that the law should permit of the export of Labrador pulp wood under an export duty, as it is considered unlikely that manufacture will be practicable at Labrador for many decades, if, indeed, it will ever become practicable.

As in most other forest-endowed countries, great losses have in past years been sustained by Newfoundland as the result of forest fires; but latterly the organisation of a forest fire patrol by the Government, with the assistance of the operating lumber companies, has, I understand, considerably reduced the danger of loss from this cause.

Thus far I have dealt, as fully as time will permit, with what are the only pulp wood producing countries in the British Empire, and before passing to a review of other actual and potential paper-making fibres from other parts of King George's dominions, it may not be out of place if I utter a word of warning against the tendency which sometimes exists to imagine that the world's supply of timber for paper-manufacturing purposes — whether in the western or the eastern hemisphere—is illimitable and inexhaustible. That this is not the case I have already indicated: but it is necessary to emphasise the fact that the production and consumption of paper is every year increasing, and involves annually a larger absorption of pulp wood, which is the staple raw material of the paper-making industry. Fortunately, the folly of the wasteful and prodigal sacrifice which too often characterised cutting operations is now recognised. The science of forestry is better understood, greater discrimination is being exercised in cutting operations, the preventive measures against loss by forest fires are more complete, and, lastly, the efforts which have for several years past been made to discover other fibres which will supplement those of wood for paper-making purposes are beginning to bear fruit. All the circumstances, therefore, seem to point to a plenitude of raw material which will meet the requirements of the paper industry for several generations to come. This desirable result can, however, only be attained by the conservation of our present sources of supply, and by the unremitting search for those new fibres which, in various parts of the world, are awaiting the opportunity of ministering to the needs of humanity.

India.

Among the various fields of investigation to which chemists and cellulose experts have devoted attention, with satisfactory results, are the vast bamboo-producing areas of India and Burma, where, it has been estimated, there are millions of acres which are either bamboo forests or are perfectly adapted for the cultivation of bamboo. In this connection, valuable service has been rendered by the Forest Research Institute, Dehra Dun, with whose work Mr. W. Raitt and Mr. R. S. Pearson are so honourably

associated. So successfully has bamboo passed the experimental stages, that it may already be said to have come within the realm of paper-making materials, and it is not at all improbable that in the near future it will have taken its place as one of the principal fibres from which paper can be produced, especially in the Far East. Up to the present, however, the only two mills for the pulping of bamboo of which I have recollection are, one belonging to the Mitsu Bishi Company (Japan) in Formosa, and the other to a Tonkin corporation near Haiphong in Indo-China.

The researches of Mr. Sindall, Mr. Richmond, Mr. Pearson, and Mr. Raitt, followed by factory tests in this country and in India, have demonstrated the suitability of bamboo cellulose for the manufacture of paper; particularly printing and litho grade, "provided its isolation has been successfully accomplished," and they show a general agreement that reduction by soda was the only practical method applicable. The commercial exploitation of bamboo was a matter of some initial difficulty owing to the fact that there were several hundreds of species growing over a wide range and variety of latitude elevation, climate, and soil. These, therefore, became the subject of an exhaustive inquiry by Mr. Pearson, the official Forest Economist to the Government of India, who arrived at what proved to be the well-founded conclusion that only five species of bamboo existed in commercial quantities and under economically exploitable conditions. In the course of a paper on the subject of "Bamboo Cellulose," presented two or three years ago at the International Congress of Applied Chemistry, Mr. Raitt stated that "though few in number, these species are so dominant in their own area that they probably represent 80 per cent. of the whole growing stand of bamboo in the country." It may, therefore, be considered that the adaptability of bamboo to paper-making purposes becomes of first-class importance, especially to our Indian Empire, where paper-mills have been not altogether remunerative, owing to the fact that much of their raw material has hitherto been brought from distant lands. Experts have already arrived at the opinion that before long bamboo will become a staple article for the production of paper in India, and Mr. Raitt calculates that it is admirably suited for probably 50 per cent. of the entire trade. "For the better classes of writing and ledger paper," he states, "bamboo pulp is not so useful, as it is lacking in the strength and firmness which is essential for these grades."

My friend, Mr. Samuel Milne, of Messrs. Bertrams, Ltd., who has made a long and deep study of the question of the treatment of bamboo, which, he says, depends more upon the plant than on the chemicals used, emphatically asserts that it is quite safe to say that no fibre available in quantity at the present moment can be superior to bamboo. He maintains that it is suitable for the highest qualities of paper, and, when properly treated, can also be converted into excellent kraft paper. Mr. Milne was good enough to furnish me with several samples of bamboo pulp, and, referring to one of an easy bleaching pulp from Tonkin, he states that it is of the thin walled type and can be treated without difficulty to produce pulp of the highest quality. As a matter of fact, he is of the strong opinion that, properly handled, bamboo can be used for practically anything for which cellulose is suitable. Mr. Milne, I believe, has for a long period been developing an improved method of treatment of bamboo by means of the ordinary caustic soda process with modifications to suit the particular necessities of the material, and to ensure greater economy of working than is at present obtained with the best plants working esparto, and is convinced that suitable bamboo can be converted into an easy bleaching pulp at practically the same cost as esparto. So certain is he of his ground that he is prepared to guarantee results.

In drawing your attention to some slides illustrating bamboo, with which my friend, Mr. Christie, has supplied me, it may be mentioned that the elements of the stem which enter into the composition of the pulp are mainly derived from: (1) The broad zone of fibres lying under the epidermis; and (2) from the fibres forming the sheath of the fibro-vascular bundles running through the whole stem. Besides these actual fibres the pulp contains parts of the large and small vessels with their characteristic markings, parenchymatous cells form the ground tissue and epidermal cells with serrated edges.

In the section of the whole stem the fibro-vascular bundles with their large vessels of wide cavity are seen disposed in fairly regular concentric rings throughout the ground tissue or parenchyma. The enlarged section of a portion of the stem shows the hypodermal layers of fibres and fibro-vascular bundles more clearly.

The longitudinal section of node and internode are chiefly interesting from the structural point of view and call for no particular remarks.

For nearly a generation the leading Indian paper-making fibre has been the baib or sabai grass (*Ischæmum augustifolium*), the similarity of which in appearance and quality to esparto leads English paper-makers in India to utilise it for paper-manufacturing purposes in that country. Again, using Mr. Raitt as my authority, "when carefully collected, free from weeds and foreign matter, it is one of the best and cleanest materials known for the production of the finest printing and medium quality writing-papers." Owing to the fact that no portions of the leaf or flower culm differ materially in composition from other portions, and that even the nodes do not suffer any serious resistance to the action of the digestion liquors, baib is easily reduced to a clean and regular pulp, and the paper made from it is scarcely distinguishable from esparto. Latterly, however, there appears to have been experienced a serious deterioration in quality and falling off in quantity collected per acre or mile. Mr. Raitt, indeed, states that baib is, in short, suffering from the effects of over-cropping, and he suggests that, in the case of certain other grasses, whose crops represent a very much larger weight per acre, factories should obtain control of areas considerably in excess of their annual requirements, so as to permit of portions being occasionally allowed to rest uncropped for one or two years.

I had a very interesting conversation with a Japanese paper-maker last year, who informed me he had completed arrangements for operating his company's mill on bamboo fibre.

This brings me to speak of the Savannah grasses of Northern and Central India, which have been the object of considerable study by the experts of the Forest Research Institute at Dehra Dun, with a view to determining their cellulose or paper-making value. Hitherto paper-making experience of grasses on a practical and commercial scale has been confined to the cereal straws, esparto, and the baib grasses of India, all of which are easily treated as they are not strongly lignified, and their nodes, or knots, are small and easily dealt with. Mr. Raitt, to whose interesting report upon the subject I am largely indebted, states that the Savannah grasses are of a very different type, being much larger and coarser, more strongly lignified, and having hard and large nodes. It is, therefore, encouraging to learn, on his authority, that the need for a strong, long-fibred pulp having some of the qualities which at present can only be obtained by the use of linen and cotton rag may probably be supplied by several of the coarse Savannah grasses common to much of the waste and thinly-forested areas of India. In the course of his report Mr. Raitt entered into an exhaustive examination of these grasses from the physical, analytical, microscopical, and other points of view, with which it would be superfluous for me to deal, but the results of his experiments in digestion with caustic soda are interesting, as showing that of ten species of grasses (List A), only two—*Imperata arundinacea* and *Eragrostis cynosuroides*—proved weak and short in fibre, difficult to bleach, and of little value except as second-class pulps to be used in mixture with stronger ones. The remaining eight species, all of which produced good strong pulps, were—*Saccharum spontaneum*, *S. arundinaceum*, *S. munja*, *S. narenga*, *Anthistiria gigantea* sub. sp. *arundinacea*, *Anthistiria* sub. sp. *Villosa*, *Arundo donax*, and *Phragmites karka*. Eight other grasses (List B) were similarly experimented with, and of these the following were found to yield good clean pulps suitable for mixing with either of the eight I have already mentioned—*Saccharum fuscum*, *Andropogon intermedius*, *A. squarrosus*, *A. nardus* and *Erianthus ravennæ*.

Each of the ten grasses mentioned in List A produced fibres of the long slender type with tapering points, ranging from 4·70 mm. to ·50 mm. in length, the outstanding feature being the marked superiority of *Anthistiria*, as to which Professor Hanausek, of Vienna, a well-known fibre microscopist, reported as follows: "With regard to length, it appears to surpass all other straw or grass celluloses. It must yield an excellent pulp, combining fineness, equality, and strength." Mr. Raitt adds that several of the *Saccharum* group approach it, as also does *Phragmites karka*, while all are regarded as first-class, possessing the features desirable for the manufacture of high-grade writing-papers, or for admixture with second-class pulps like bamboo, in order to gain firmness and strength. The eight grasses which have thus received the benediction of experts, and which are calculated to be capable of adding several million tons annually to the paper and pulp-making resources of India, are found over a wide area extending from Sind to Burma, with the result that there must be wide divergencies of manufacturing facilities, labour, freight costs, etc. Mr. Raitt aptly summarises the position when he states: "As a general rule grass districts connote inland, upland, and comparatively dry country, with long railway leads to seaports, coalfields, and

paper-mills, and an absence of the cheap water transport frequently found associated with bamboo. An exception to this will probably be found in the extensive grass-covered Savannahs on the banks of the Brahmaputra and its tributaries. The cost of cutting and collecting will also be more than for bamboo, as the greater size and weight of the individual culms of this material permits a larger quantity of it to be collected per coolie per day, so that generally, and especially in the absence of water transport, the cost of grass pulp must exceed that of bamboo pulp. This, however, will be compensated for by its better market value."

Mr. Raitt provisionally estimates that the cost per ton of unbleached pulp at the factory would work out at between 100 and 119 rupees, and goes on to say: "Unbleached baib pulp cannot be produced in our local paper-mills with their long railway lead on raw material for less than 155 rupees, and in some instances 170 rupees per ton. The former figure may, therefore, be regarded as their minimum market value, and it is less than the delivered cost of the European chemical wood pulp now being imported to make up the shortage of baib. There is, therefore, a margin on the above estimated costs of from 35 to 55 rupees available for manufacturer's profit and payment of freight to consumer."

Another potential paper-making material which has been described as a native of India, being distributed from the Himalayas to Ceylon and Malacca, is *Hedychium coronarium*, to which Mr. Clayton Beadle and Dr. Stevens drew the attention of the Royal Society of Arts a little more than two years ago. Brazil, however, appears to be the fibre's chief home so far as it may be said to come within the scope of the paper-making industry, and it was in that country, at Morretes, Parana, that rough paper was first produced from it. Subsequent to the Royal Society of Arts communication, Messrs. Beadle and Stevens in my own journal, *The Paper Maker*, and in other ways, have outlined the result of further investigations with regard to *Hedychium*, and it is interesting to note that their tests of some dried-down specimens of the plant from Calcutta were satisfactory in result. They were boiled with 10 per cent. (of 77 per cent.) caustic soda for four hours at two and a half atmospheres, washed free of liquor, and lightly brushed for three hours in a hollander, then made into paper without any sizing material. The conclusion is arrived at that from 80 to 90 per cent. yield of paper on the raw dry fibre weight can be obtained. The paper manufactured from the Calcutta sample is described as "good," although not like the Brazilian, but the yield is said to have been much lower. Unfortunately, however, the upshot of Messrs. Beadle and Stevens' inquiries, stated in their own language, is "that there is no real promise of success outside the State of Parana, Brazil, in which country it grows in wild abundance and profusion." Quite recently the experts I have mentioned have tested a sample of the stems of *Hedychium flavescens* forwarded to Kew by the Director of Agriculture, Ceylon, in order that its paper-making qualities might be compared with that of *Hedychium coronarium*, and I gather that the results of their investigation show that the stems of *Hedychium flavescens* furnish a paper of similar character to that afforded by the stems of *Hedychium coronarium*, but in somewhat lower yield.

Another grass to which the attention of the Research Institute, Dehra Dun, India, has been drawn is moya grass (*Pennisetum Alopecuros*), which, reports state, yields 39 per cent. of easy bleaching pulp similar in quality to that obtained from baib grass. It is said to grow over large areas in the hills of the Central Provinces, and to be capable of collection at a low cost. It is, indeed, considered that in the neighbourhood of the Pench Valley Coalfield --says a Bulletin of the Imperial Institute— 15,000 to 20,000 tons could be collected annually at a suitably situated factory site, at a cost not exceeding 15 rupees (£1) per ton.

Quite a number of other plants, chiefly from India, have also been examined, tested, and reported upon during the last few years, among them being *Iris ensata* var. *Oxypetala*, abundant in Kashmir; *Musa textilis*; and *Spatholobus Roxburghii*, collected in Bengal. The results, however, were not of a very satisfactory character. The leaves of the *Iris ensata* were found to contain 42·3 per cent. of cellulose calculated on the dry material, which is a much lower percentage than is usually present in esparto grass, and it is considered improbable that they could be used as a source of fibre, and that they could compete with such cheap material as esparto grass or wood pulp. *Musa* sheaths contained a much lower percentage of cellulose and a higher percentage of ash than esparto grass. This fibre might be utilised in the manufacture of Manilla papers, but could not compete with Manilla rope. In the

tests of *Spatholobus* negative results were obtained.

There is one other great source of fibre which India might profitably exploit, viz., the cotton seed cotton obtained from the down of the cotton seed by a process of dry mechanical separation. Beadle and Stevens, in recent years, have very carefully investigated the question of the paper-making possibilities of this fibre, and from hulls shipped from India, as well as from the United States, paper has been made. The Indian fibre, however, is of shorter staple than that from the States or Egypt, and, moreover, the notoriously dirty condition of Indian seed prevents the mechanical separation of the cotton being as remunerative as that from the Brazilian or the American seed, the product from which is now used in large quantities in place of rags for the highest qualities of paper, thanks to the mechanical improvements initiated by Minck, and subsequently brought to a state of perfection by E. de Segundo.

Among other Indian fibres to which attention has been directed is lallang grass, in connection with which, it is interesting to recall, the then Sultan of Johore granted a concession in 1902, when the material came under investigation by Messrs. Cross, Bevan, and Beadle, particulars of the results being published in the form of a brochure. This matter has become of greater importance during the last few years on account of the fact that the various rubber estates in the East are obliged to make war upon the lallang grass, and hundreds of thousands of pounds have been expended in uprooting and destroying it. Messrs. Beadle and Stevens, however, brought the paper-making qualities of the grass before the notice of the rubber trade in 1908, and I believe that since that period it has been very carefully considered as a possible means of revenue. The pulp producible is not unlike esparto in its paper-making qualities, but other investigations in the Malay States, where the grass also grows in large quantities, seem to show that lallang is more successful as a paper pulp producer when used in conjunction with different kinds of pulp.

Trinidad.

The sugar plantations of the Western and Eastern hemispheres, too, may be found to yield a paper-making fibre which, treated locally, might form the nucleus of a useful industry. I refer to bagasse, the refuse of sugar-cane after roller-crushing for the expression of the juice, which contains about 50 per cent. of available cellulose, yielding about 45 per cent. of air-dried unbleached pulp. The fact that bagasse is, in most cases, the only fuel which the cane-crusher uses, being much cheaper than coal, would possibly affect the supply for paper-making purposes, but experiments have shown, as in the case of those conducted by Bert de Lamarre in Trinidad, that when mixed with other fibres it produces a useful paper. The best results are said to have been obtained with a mixture of bagasse, bamboo, and Para grass. In Trinidad alone there are estimated to be 50,000 tons of bagasse available per annum. This quantity would yield 40,000 tons of pulp of a value of at least £200,000, or 30,000 tons of a pulp of better quality worth £360,000. Mixed with bamboo and Para grass, the pulp, says one authority, would be worth £450,000. Writing in the *Tropical Agriculturist* four or five years ago, Mr. W. Raitt estimated that the value of bagasse as a raw material for paper-making at the sugar factory was 40*s*. per ton, while its value as a fuel was only about 7*s*. 6*d*. per ton.

Bamboo is, I believe, receiving serious attention in Trinidad. A firm there has been engaged in pulping bamboo for paper-making purposes for some time past.

Australia.

The constantly increasing demand for paper in Australia is chiefly met by imports from this country, Canada, and the United States, but for several years past the idea has been entertained that it should be possible to establish the nucleus of a pulp and paper industry in the Commonwealth. Whether the idea will ever be realised and when, is, however, still in the lap of the gods, though within the last two years a mill for the production of sulphate pulp from a kind of pine wood similar to Riga fir, but of a rather more yellow colour, has been opened at Yarraman Creech, 120 miles north-west of Brisbane, Queensland. At the opening ceremony, the Governor (Sir William MacGregor) described the mill as the first of its kind in Australia. He also expressed the conviction that Australia possessed many growths from which paper could be manufactured successfully, among them being the prickly pear and grass, at the same time considering the destruction and waste of fine timber in Queensland were disgraceful. Upon what grounds Sir William based his conviction I am unable to state, but it is historically interesting to learn that as far back as 1867 the value of some

Australian grasses allied to esparto was discussed in an article which appeared in the report on the Industrial Exhibition in Melbourne, and samples of paper, I am informed by the Agent-General for New South Wales, made from several kinds of grass were prepared by Baron F. von Mueller for that exhibition. That was forty-eight years ago, and the fact that if any further steps were taken in the matter they did not result in anything of a permanent character may be regarded as presumptive evidence that the manufacture of paper from them on a commercial basis was not likely to be successful. As a matter of fact, until the establishment of the Yarraman pulp-mill, I am not aware that the possible paper-making materials of Australia have been tried under commercial conditions. There seems, however, to be a considerable number of Australian grasses, rushes, and sedges which have been proved to be well adapted for making into fibre or paper. These include sedge grass (*Carex appressa*), false sedge (*Carex pseudo-cyperus*), black reed or cutting grass (*Cladium radula*), shining rush (*Cyperus lucidus*), sword grasses (*Gahnia psittocorum*), nodding rush (*Isolepis nodosa*), sea-coast rush (*Juncus maritimus*), small rush (*Juncus pauciflorus*), sheathed rush (*Juncus vaginatus*), tall sword-grass (*Lepidosperma elaitus*), slender sword rush or mat grass (*Lepidosperma flexuosum*), coast sword rush (*Lepidosperma gladiatum*), tussock grass (*Poa coespitosa*), and club rush (*Scirpus fluviatilis*). I am informed that probably the most widely-spread paper-making material native to Australia is the *Cyperus textilis*, a very good fibre plant, found in every part of Australia where swamps exist, which is converted into pulp very easily, and makes, I understand, very good writing-paper. It is a perennial plant, and the annual cuttings give a very good return for the small areas. The sword rush (*Lepidosperma gladiatum*), which I have just mentioned, also grows very well in the extra-tropical parts of Australia along the sea-coasts, and also makes a very good paper. Its principal use at present is for binding sea-sand.

Among other Australian fibres, in addition to the fibrous refuse of Queensland sugar-canes known as "bagasse" (or "megasse"), to which attention has been directed, are those of the black-boy tree (*Xanthorrhœa Preissii*) from Western Australia, *Posidonia Australis* from the sea-coast of South Australia, the prickly pear (*Opuntia*), and the slender spike rush (*Eleocharis acuta*). With regard to the last-named, many years ago Dr. Mueller spoke of it as a good paper stock, stating that the local experiments showed it and other cyperaceous plants to be well adapted for good printing and tissue paper and a by no means inferior writing-paper.

Tasmania, the smallest of the States of the Australian Commonwealth, is famous for its variety of forest trees, and it is possible that in these days of scientific research the time is not far distant when much that is now destroyed as worthless in the Tasmanian forest will be utilised for many purposes at present unthought of. Whether any considerable portion of it will ever be devoted to the production of pulp for paper-making purposes is difficult to say; but I am interested to learn from Sir John McCall, the Agent-General for Tasmania, that the Government are engaging an expert to visit Tasmania to report on the possibility of establishing the wood pulp and paper-making industries there. The question is, of course, a new one for Tasmania, and I understand that up to the present only experiments have been conducted with a view to testing the adaptability of Tasmanian timbers and fibres to paper-making uses. Sir John McCall, however, was good enough to send me a specimen of paper made from the blue gum tree (*Eucalyptus globulus*), which it may interest some of you to examine. The wood from which the paper was made was sent to this country for telegraph arms, and had been exposed to the weather for some three years. Some pulp has also been made, I am informed, from stringy bark (*Eucalyptus obliqua*), and there are many other kinds of wood which it is considered will be equally adaptable for the purpose of paper-making. Should this prove to be accurate, a valuable by-product will have been discovered.

NEW ZEALAND.

I have unfortunately been able to trace but little official or authoritative report upon the pulp-producing resources of this beautiful country; but, through the kindness of the High Commissioner for New Zealand, I have been afforded the opportunity of perusing a little work on "New Zealand Timbers and Forest Products," written by Sir Westby B. Perceval, K.C.M.G., a former Agent-General for New Zealand, who mentions three species of wood which had been suggested as admirably adapted for the manufacture of wood pulp. The first is the white pine (*Podocarpus dacrydiodes*), a large timber tree, the wood of which is very white, cheap, and plentiful all over

New Zealand, and which is called by the natives "Kakika." Of the second, houdere (*Hoheria populaea*), he states that it is found all over both islands, grows to a height of 45 ft., and a diameter of 2 ft., is white in colour, plentiful and cheap. The third tree is named Ti kouha (*Cordyline Australis*), and grows on river banks and on the margin of boggy woods to a height of 30 to 40 ft., and a diameter of 5 ft. The leaves of this plant, writes Sir Westby, afford a material for paper-making of great value, as well as fibre for cordage.

Dodge's valuable work on "Useful Fibre Plants of the World," indicates that the second of the three woods I have mentioned is the ribbonwood of Otago, resembling the aspen tree. It also quotes Dr. Guilfoyle's opinion, that "the delicate lace-like bast from its young branches, being strong and glossy, might be used for other purposes than matting and string." Whether any serious attempt has been made to determine definitely the adaptability of either of these fibres I have not yet discovered; but though the Dominion undoubtedly possesses forests containing certain kinds of woods suitable for paper manufacture, it seems probable that most of it is too hard for cheap conversion into paper, and that it can be used more profitably for other purposes.

Experiments have, however, been conducted with a view to ascertaining whether plant fibres grown in New Zealand may usefully be adapted to paper-making purposes. Among these is New Zealand flax (*Phormium tenax*), a fibre extensively grown in the islands and of more particular value for textile purposes. From this, Messrs. Beadle and Stevens inform me, very strong paper was produced. The fibre has been the subject of a somewhat extensive inquiry by the New Zealand Government with a view to its cultivation. Dodge states that *Phormium tenax* will grow in almost any soil, but best on light rich soil by the side of rivers and brooks, where sheltered from the wind. He says that a well-drained swamp gives large returns, and that on the best lands an acre may contain 2,000 bunches on the plant, or 100,000 leaves. The planting, however, must be very close.

British Africa.

Under this comprehensive heading I propose to discuss, as fully as time will permit, some of the numerous fibres growing in those parts of the great African continent which are within the British Empire. It is, of course, impossible to do more than to touch the fringe of what is really a vast subject, but sufficient may be said to indicate the immense possibilities these regions furnish for the extension of the world's paper-making resources.

Commencing with South Africa, whence from time to time come rumours of enterprises having for their object the manufacture of pulp and paper, it must be said that the question of what native fibres are suitable for paper manufacture is as yet only partially decided. During recent years, experiments have proved pretty conclusively, it is stated, that a number of fibrous materials are particularly suitable for the purpose. Among these may be mentioned maize and banana leaves, the prickly pear, sisal hemp, wattle bark, tambookie grass, papyrus grass, and bagasse. I understand, however, from Mr. A. Canham, the Acting Trades Commissioner of South African Government, that up to the present only three classes of material—the three last-named—have been experimented upon. Vast areas of country in Zululand and Northern Transvaal are covered with papyrus and tambookie, and it is thought that if the material could be worked up into a pulp in South Africa, and exported in that form, a very large trade could be done. As a matter of fact, Mr. Canham informs me that quite recently the South African Government leased to a firm in Johannesburg certain ground in Zululand for the cutting of papyrus grass, and that he had been advised of the dispatch of 25 tons of that fibre to this country for purposes of experiment. Last year a sample of papyrus was forwarded to the Imperial Institute and was made the subject of a report, from which I gather that it was obtained from the St. Lucia Bay districts of Zululand, and consisted approximately of 80 per cent. of stem and 20 per cent. of leaf tufts. Upon the completion of the tests it was found that the yield of pulp was less than the quantities obtained from papyrus stems from East Africa and the Sudan. The pulp was readily obtained from the papyrus by heating with caustic soda under pressure, and was easily bleached, being thereby rendered almost white. Paper-making trials showed that the pulp could be converted into a satisfactory paper of good strength. Unfortunately the conclusion arrived at was that, owing to the rather low yield of pulp and the bulky nature of the papyrus, it was unlikely that it could be profitably exported to Europe in the crude state, in which it would probably not realise more than about £3 per ton in the United Kingdom. It could, however,

be converted in South Africa into "half-stuff" for export, or it could be used locally for the manufacture of paper. Mr. Canham was good enough to send me two samples of the paper made from papyrus stem and leaves, which may be of interest.

Even a more satisfactory report was made by the Imperial Institute upon tambookie grass from the Transvaal, which grows luxuriantly over large tracts of country. The results of the chemical examination of the grass in comparison with Algerian esparto grass from Oban showed that the yield of unbleached pulp (dried at 100-110 c.) expressed on air-dry material was 37·1 per cent. compared with 29·3 per cent. esparto, and expressed on material dried at 100-110 c. the percentage was 41·3 compared with 32·3 esparto. The yield of bleached pulp (dried at 100-110 c.) expressed on material dried at 100 110 c. was 40 per cent. as against 32 per cent. esparto. The report states that on heating with caustic soda solution under pressure the tambookie grass was readily converted into a light fawn-coloured pulp, which was very easily bleached to a pure white product. While the yield of pulp was unusually high the average length of the ultimate fibres (0·081 in.) was considerably greater than in the case of esparto (0·045 in.). Paper-making trials carried out at the Imperial Institute showed that a satisfactory paper of fairly good strength could be produced, as will be seen from the unsized and unfinished specimens which I have here. The high yield of pulp of good quality and the ease with which the pulp was bleached show that tambookie grass is well adapted for paper-making, and the crude material would probably be worth about £4 per ton in the United Kingdom. It is, however, considered that it would probably be more remunerative to convert the grass into "half-stuff" in South Africa, and either send it to Europe or utilise it locally for the manufacture of paper.

In connection with the mention of wattle bark as a paper-making material, I was interested a few years ago in reading in the *Chemical Trade Journal* an article on "The Chemical Industries of Natal," in which wood distillation and wood pulp and paper-making were included among probable industrial developments in South Africa. The writer, after stating that every year many thousands of tons of wattle wood from which the bark is stripped find no use, and that its suitability for distillation was second to none, went on to assert that the wood would form the raw material for paper-making purposes, and that tanning compounds, which exist in the wood to a less extent than the bark, would pay for extraction before the pulping process commenced.

A fibre which has been the subject of paper-making trials at the Imperial Institute is Spanish reed (*Arundo donax*) from the Transvaal. The species of this grass known to the ancient warlike Jews, I may parenthetically remark, was greatly valued by them after they began to practise archery with effect, because its long, straight, and light canes made excellent arrows. A fairly good paper was made from the sample tested at the Imperial Institute, but the chemical examination showed that, compared with esparto grass, the yield of pulp calculated on dried material was 27·6 per cent. as against 32·3 per cent., and the loss on bleaching was much greater. On treatment with alkali the pulp was pale yellowish-brown and was easily bleached.

Aristida sp. from the Transvaal was also experimented with, but the paper produced from it was generally of poor quality, mainly through the shortness of the ultimate fibres of the pulp. It is, therefore, considered doubtful whether this grass could be used alone for paper-making, and that it would be necessary for it to be employed in conjunction with material having longer fibres.

Among other fibres from South Africa which have been brought under the notice of the Imperial Institute were *Helichrysum* from the Transvaal, and *Moræa tricuspis* from the Cape of Good Hope. Results of tests showed that the leaves of *Helichrysum* would no doubt serve as a paper material, as they contain a large proportion of cellulose and an ultimate fibre of good length. This, however, would depend upon the cost of the material as compared with that of esparto grass or wood pulp and upon the quality of the paper it would yield, a point which could only be ascertained by technical trials with large quantities of the material. *Moræa tricuspis* fibre contained a higher percentage of fibre than esparto, and could, no doubt, be utilised for paper-making, though perhaps only locally.

From other parts of British Africa have come many other more or less likely paper-making fibres, but I think the purposes of this paper will be adequately served if reference is now confined to those which appear to present superior possibilities from the paper manufacturers' point of view. In this category may be placed the baobab tree (*Adansonia digitata*) which grows in great abundance in West and East Africa and is often called the "monkey

bread tree of Africa." The tree grows chiefly, I believe, in immense clusters or small forests near the sea and is rarely far from the coast, and is one of the largest and longest-lived in the world. It is said to possess properties which render it of exceptional value for paper-making, and is used by the natives for the manufacture of ropes and sacking. Something like thirty years ago it was held in considerable esteem in this country by manufacturers of "small hands" (strong light-coloured wrapping papers), and good parcels are said to have ranged in value from £8 to £10. In order to prepare the fibre, the hard outer bark is first removed by chopping, and the inner bark is then stripped off in large sheets. About three years ago Mr. P. H. Stormont, the Acting British Consul-General at Dakar, reported that "the baobab makes a paper of superior quality and durability suitable for banknotes," which seems to be an advance upon the uses to which it was put a generation ago. He also observed that, added to other pulps in small quantities, it imparted a gloss and finish to the paper. A concession to work some baobab forests was granted a few years ago to a French company, but owing to wrong methods of working and lack of funds the factory was abandoned. It has since been suggested, however, that with fresh capital and under good management the concession would be made to yield a good profit.

Elephant grass (*Pennisetum purpureum*) is another plant which has occupied the attention of the experts of the Imperial Institute, with results that suggest that "if the stems were converted into pulp in Africa by treatment with caustic soda, it is possible that a remunerative industry might be carried on, since the pulp would probably be of approximately the same value for paper-making as wood pulp prepared by the soda process." A perennial grass, it occurs in a wide zone across tropical Africa, and is found chiefly along watercourses and in marshy depressions, but also grows in the more open parts of the bush and forest, while in the delta of the Zambesi and along the Shire River it forms extensive reed jungles. Tests of a sample of the dried mature grass from Uganda, weighing 177 lb., were some time ago made at the Imperial Institute. The pulp was a good colour, and was composed of ultimate fibres rather longer than those of esparto and of about the same length as those of bamboo pulp, and the sample furnished a fairly good paper. No difficulty appears to have been occasioned by the nodes, and it is considered that there is no necessity to cut them out when utilising the stems for paper-making. In view of the fact that Togoland is now in British hands it may be interesting to mention, however, that the nodes are stated to have caused some difficulty in trials carried out in Germany with elephant grass from that part of Africa.

Considerable attention has also been paid within recent years to the papyrus of the Sudan as a possible fibre for paper-making purposes. It is, of course, unnecessary here to refer to the historic connection of papyrus (*Cyperus papyrus*) with the making of paper, but it is interesting to recall that the ancient Egyptians used it in the preparation of writing-paper, which was made from the inner bark of the stem. Time, however, prevents me doing more than allude to the tests which have been applied to the fibre with a view to ascertaining its utility under modern paper-making conditions. Samples of papyrus from the Sudan and the East Africa Protectorate were some time ago experimented with, when it was found that the yield of pulp from the East African papyrus was slightly less than that from the Sudan sample, but was of similar character and quantity. Paper-making trials showed that the manufacture of fairly good paper from this material is possible. Expert opinion, however, was to the effect that the air-dried material would not realise so much per ton in this country as esparto grass. The commercial possibilities of papyrus have more recently been the subject of further investigation in connection with the flotation of a company for the production of sudd fuel and papyrus pulp, and with regard to the latter it was stated that "it would be possible to place on the London market, at a cost of three guineas per ton (including transport, canal dues, etc.), unbleached papyrus pulp, the sale price of which has been estimated by experts at £6 10*s*.," leaving, roughly, a net profit of about £3 a ton. It was, I understand, decided by the company to introduce a pulp-making plant on their site in the vicinity of Lake No, and if results justified it a subsidiary company was to be formed for the purpose of pulp manufacture. Of later developments, however, I have, unfortunately, no personal knowledge.

Federated Malay States.

For some years past suggestions have been made in the direction of paper-making in the Federated Malay States. In the year 1910 a gentleman largely interested in that country gave, in the ***Financial Review of Reviews***, an

article, in which he referred to the wastage of wood, and expressed wonder that "in this age, when wood pulp has grown in value as a marketable commodity, it had not occurred to someone to make revenue out of the vast quantity of timber now wasted in the Malay States." So far as I am aware, however, nothing practicable was done in this direction, and the paper required there is still sent from Europe, or in even larger quantities from China. Quite recently an important British company, controlled in London—a company, by the way, concerned particularly in the growth of rubber—has been experimenting with pineapple leaves and the nipa palm, with a view to turning these fibres to commercial account.

One of our leading experts has been employed in ascertaining the commercial value of these fibres, and with regard to the pineapple fibre it was found that these samples intended for textile use were promising, although probably the experiments made up to the present are somewhat indefinite. Pineapple combings gave excellent results for paper-making, and the samples of paper made in London recently appear to offer considerable promise, although apparently the combings were somewhat dirty, and this is obvious when the samples are examined. It was found that, taking an average sample of pineapple combings and treating the same by the soda process for the manufacture of paper pulp, digesting for six hours with caustic soda at 50 to 60 lbs pressure, there was a yield of unbleached fibre of 38 per cent. The material was strong, but it will be noted that the yield was low. In another test, where the fibrous matter was selected, a yield of as much as 73 per cent. of useful fibre resulted, and the general testing indicated that by proper separation of the more fibrous portion, with suitable mechanical appliances, a good product is readily obtainable.

Mr. Clayton Beadle, who, I may mention, made these tests, came to the conclusion that the experiments all tend to show that a clean combing of the pineapple leaves will give a strong, serviceable pulp, capable of being bleached to a good colour.

The sample of nipa palm, also submitted by the same rubber company to Messrs. Sindall and Bacon, has, within the past few weeks, been very carefully experimented upon, and some of the samples produced are distinctly promising. I understand that the freight to Great Britain on rough pulps would be in normal times about 27*s.* or 30*s.* per ton in bales, and probably firms interested in making strong brown papers, or fibre boards, might, under favourable circumstances, turn the nipa palm fibres to good account.

I learn that the fronds gave a somewhat low yield of pulp, which pulp, however, is capable of being bleached readily, but the combings with 15 per cent. of bleaching powder gave a yield of bleached pulp of 29 per cent. and the pulp is of excellent quality, although showing traces of iron rust. The lowness of the yield is an important factor in the consideration of this fibre. Having regard to the poor yield of bleached paper pulp obtained, Messrs. Sindall and Bacon have made an experiment for the production of tough boards from the combings with a minimum of chemical treatment. The raw material was, I learn, simply warmed for two hours in a very weak solution of caustic soda in an open vessel. The product was washed and treated in a beating engine, and finally made up into thick paper, a sample of which I have here, and the result is a tough, strong board, suitable for boxes, fibre and portmanteau boards. This experiment indicates that the combings can be put into a beating engine and converted directly into tough, fibrous boards without any chemical treatment whatever, and not only boards, but tough wrapping paper could be cheaply produced. Thus, it is pointed out, a material quite unsuited for white papers can be profitably utilised for strong wrappers and stout box boards. I have reason to hope that further experimental work will be carried on in the Malay States, and although these fibres are not likely to revolutionise the paper-making industry, they offer promise as a material for box boards.

For those interested in the subject I will present a conventional diagram of the arrangement of a small experimental plant such as Messrs. Sindall and Bacon have actually recently designed, and a plant of this type has been made in London by Messrs. T. J. Marshall and Co., of Stoke Newington. It is estimated that a small plant capable of producing 10 or 12 tons per week would cost, approximately, £3,000, and a small experimental plant capable of producing paper or pulp boards 12 ins. wide would, I suppose, cost £350 or thereabouts.

It is interesting to note that the Government has shown considerable interest in regard to the development of fibres in the Malay States, and this interest has taken practical shape, as a small experimental plant for the treatment of fibres has been installed in order that the experiments may be continued.

I am now approaching the end of my task, but before bringing this somewhat discursive and, it is to be feared, incomplete review of "The Empire's Resources in Paper-Making Materials" to a close, it may not be out of place if I briefly allude to one or two considerations which have occurred to me as bearing upon the situation brought about by the great struggle in which this country with its Allies is now engaged. May we not, for instance, legitimately ask ourselves how far the British Empire is of itself able to furnish the raw materials for the paper-making industries in its own borders?

Our present dependence upon the Scandinavian countries for supplies of chemical and mechanical pulp has not been without a certain amount of risk to the interests of the British paper-making industries, and it is conceivable that had Norway or Sweden ranged themselves in the ranks of our foes, or been effectively prevented from conducting their export trade, a serious position would have arisen. With a ready market for its pulp exports at its own door, and with contracts to fulfil, Canada could scarcely be expected to meet anything like the requirements of this country. Where, then, should we have looked?

Surely, therefore, it becomes a matter of supreme importance that we should endeavour to supplement what may be described as our foreign sources of supply with those which are awaiting exploitation and development within our own world-wide Empire! Inquiries tend to confirm the belief that various parts of the King's dominions are rich in fibres adapted to paper-making purposes, and that there is a vast field over which "the banner of England flies," towards which British science and enterprise may profitably be directed. Many of the fibres to which I have referred have probably no real commercial value from the paper-makers' point of view, but there are others whose utility have been amply demonstrated. As yet, however, we are but on the fringe of a world of possibilities, in which even the desert places of the earth, the swamps and marshes of virgin lands, as well as the unexplored forests of two hemispheres, may possibly minister to that industrial, commercial, and intellectual progress for which paper is so great a necessity.

Before closing I would like to express my great appreciation of the encouragement and assistance I have received from Professor Dunstan, Director of the Imperial Institute; and the selected reports from the Scientific and Technical Department of the Institute bearing on fibres and issued as Colonial Reports (Miscellaneous), are of extreme value and contain a mass of information of first-rate interest to paper-makers. No. 58 (Cd. 4588) is well worth perusal, and Volume No. 12 (1914) of the Official Bulletin also contains a number of matters showing how the Institute has thoroughly investigated fibres which may be of more or less use in paper-making.

I am also greatly indebted to Professor Dunstan and Dr. Goulding for the loan of some specimens which are not available to the general public, and these I have very much pleasure in handing round. They are exceptionally instructive, showing, as they do, the plant, the fibre in various stages, finished papers, and particulars are given as to the yield and general characteristics. Other Imperial Institute bulletins of interest are No. 3 of Volume 10 (1912) and No. 1 of Volume 11 (1913), the last-named dealing specifically with elephant grass.

To Mr. J. M. Hillier, Keeper of Museums at the Royal Botanic Gardens, Kew; Mr. R. W. Sindall, Mr. Bacon, Mr. John Christie, Mr. Clayton Beadle, Dr. Stevens, and others I am also greatly indebted for many useful suggestions and much useful information, and to all I tender my sincere thanks. May I also add an expression of my sense of the honour conferred upon me by the Hon. Sir George Perley, a member of the Canadian Government, in consenting to preside on this occasion? Sir George's official position in Canada and in this country, as well as his association with the great lumber industry of the Dominion, render his presence here singularly appropriate and significant, and I am sure you will all share my appreciation of his kindness in consenting to take the chair this evening.

DISCUSSION.

THE CHAIRMAN (the Hon. Sir George Perley, K.C.M.G.), in opening the discussion, said he was greatly interested in the subject, because before he took up the business of serving the public he was engaged in Canada in the timber and lumber manufacturing business. In his younger days he handled nothing but white pine, but subsequently some red pine was dealt with. White pine was the wood of the greatest value in Canada, but of late years, owing to the increase in the pulp-making industry, spruce had come very much to the front, and was being cut down and used very extensively in Canada. The author had stated that white spruce was the best wood for pulp-making, but

balsam was used with it. Those two woods were cut together and manufactured together, and that plan seemed to work very well indeed. The slide the author had shown of a white spruce was rather unfair to the white spruce of Canada, because it was a field spruce growing in the open, whereas the spruce trees in that part of Canada from which he came were of a large size, occasionally having a diameter of 3 ft. at the base. The black spruce grew only to a small size in Canada. Spruce and balsam grew almost everywhere in Canada, the quantities being small in the prairies in the west, but in every other part they were very numerous. The endeavour of the pulp-mills was to get enough timber at their command to keep them going indefinitely. In his experience spruce grew about 3 per cent. in a year, *i.e.*, in thirty-three years it would reproduce itself, so that a mill which had enough standing timber to last it for about thirty-three years could practically go on indefinitely. The science of forestry had not made a great deal of progress in Canada except of late years. Latterly a good deal of attention had been given to it, and some of the large pulp companies employed trained men for the purpose of estimating their timber, finding out the best way of preserving it, and making it a perpetual business. Fire had been a very serious danger in Canada; in fact, to his mind there was no question that more timber had been burned in Canada than had been cut. Of late years it had been found possible to regulate that to a very large extent. Most of the standing timber in Canada was on land that still belonged to the Crown—*i.e.*, it was owned by the different provinces of the Dominion or by the Dominion itself, and the firms or individuals who were in the lumber or the pulp business leased that land from the provinces or the Dominion under certain regulations. They paid a stumpage to the Crown when they cut the timber, and consequently both the Government of the provinces or of the Dominion and the company or the individual who had leases from the Crown were interested in preserving the timber. Of late years a very good system of fire control had been developed by employing men to watch the fires and put them out when they were in an incipient stage; that had been comparatively inexpensive, and had produced very good results. The people of Canada intended to pay more and more attention to that very important question, in order to conserve their immense supplies of timber.

Sir Daniel Morris, K.C.M.G., D.C.L., D.Sc., expressed his appreciation of the wide survey presented by Mr. Phillips of the Empire's resources in paper-making materials. It was, however, impossible in the short time available to discuss the relative merits of the numerous subjects referred to. He (the speaker) had been closely interested in the scientific investigation of many of them. He did not wish to discourage efforts that were being made to utilise such sources of paper-making as the bamboo, the gingerlike *Hedychium*, the megass of the sugar-cane, the papyrus and the numerous tropical and sub-tropical grasses that had been referred to, but he must frankly say that he was not hopeful that any of them could replace wood pulp as long as the latter was obtainable in adequate quantity and at prices not appreciably higher than those now ruling. If the vast forest areas existing in the Dominion of Canada and in Newfoundland were efficiently protected from destructive fires, and dealt with under more scientific and remunerative methods, they would prove enormous sources of wealth. It was encouraging that in recent years Canada had increased its forest reserves for the production of lumber and wood pulp from 7 to 152 million acres. The speaker then referred to the resources of Newfoundland, which he thought had not received the attention they deserved. He recognised that Newfoundland was now the home of two of the world's finest paper-mills, and that was proof of its unequalled pulp wood resources, but its enormous capabilities for further extension appeared to be only very slowly realised. Its proximity to the British Isles, its unlimited supply of small spruce and fir growing thickly together and conveniently located near the numerous lakes and rivers, and its comparatively abundant supply of cheap labour, appeared to give Newfoundland a great advantage over any other portion of the Empire in the production of wood pulp and paper.

Mr. Alfred W. Foster (Secretary of the Paper Makers' Association of Great Britain and Ireland), speaking from the point of view of the paper-makers, said they were prepared to make paper from any fibre that was capable of being turned into paper, but it was necessary for the Empire in supplying them with the fibre to remember two things, the first being that paper nowadays was not intended for permanent use. The paper-maker who made paper for the periodical press had to produce an article which had a life of only a few minutes or a few hours, and further which had the peculiar property that the more flourishing was the concern which turned it out the more of it they had to give away for the same money. A paper which was not flourishing was small in size and consumed little paper; the prosperous newspaper having a large advertisement circulation gave away from twelve to twenty pages of the same size. Therefore a paper-maker who was making news had to turn out something which would not be durable but cheap, and the whole point with regard to fibre from which newspaper was to be produced was that it should be brought to this country and marketed at the cheapest possible

rate. That did not apply to certain high-class forms of writing-paper, the material for the production of which was ample and would not be exhausted. The principal problem in regard to the production of fibre was so far as it related to the very large class of cheap papers, particularly of news. That meant that paper-makers in this country had to be supplied with some material which could be used to turn out paper at a penny a pound. The practical point which it was necessary to bear in mind in considering the fibres available in different parts of the Empire was that the manufacturers of paper for newspaper purposes must have either the waste by-product of some other industry, such as the crushed fibre of sugar-cane, or some plant or tree which would grow wild without the expense of labour for the purposes of cultivation, and that was the practical limitation from the paper-maker's point of view of the fibres that could be used for the basis of his product. Apart from that, paper-makers could use any vegetable substance which was capable of giving fibre, and they looked with expectation to their commercial friends within the bounds of the Empire to point the way to those vegetable fibres, and to their scientific friends to show the practical method of turning them to use as the basis of the paper-making industry. On behalf of the Paper Makers' Association, he desired to add his thanks to the author for one more addition to the many very useful contributions he had made to the success and prosperity of paper-making.

Mr. Clayton Beadle said he remembered that at the Indian and Colonial Exhibition, which was the first systematic attempt to investigate the various fibres collected from different parts of the Empire by a number of experts, Mr. Routledge was endeavouring to introduce bamboo for paper-making purposes, he already having previously successfully introduced esparto. He also remembered that Mr. Lloyd, the founder of the present firm of Edward Lloyd and Sons, and father of the present generation, was at that time also looking out for new sources of supply for the manufacture of news, and that Mr. Donkin, a member of the firm of Bryan Donkin, was also greatly interested in the subject. The reports which were issued subsequent to that exhibition—one dealing with the colonial fibres being issued under the auspices of the Royal Society of Arts, and another dealing with the Indian fibres being issued under the auspices of the Indian Government—were very exhaustive, and the methods there employed had formed the basis of the methods used by chemists during the last twenty years. He had had a good deal to do in this country with marram grass, which abounded in certain districts and which was very valuable as a sand binder. It grew very thickly, but its yield, as compared with esparto, was somewhat disappointing. Nevertheless it was possible that that fibre might be of service in the manufacture of certain classes of printing paper, and it was the only fibre that he knew of in this country which showed any promise of being of service in that direction. A good many years ago, and again recently on behalf of the Rubber Growers' Association, he had a great deal to do with lalam grass. It had proved itself a pest to the rubber growers, and it had now been eradicated by burning and rooting it up. It was a paper-making plant, but it was regarded as an enemy by rubber growers, and he therefore thought very little would come of it. In conjunction with Dr. Stevens, he had under examination forty-three plants sent over from India which had all been classified at Kew, from many of which paper had been made. They were closely allied to the *Hedychium*. He had been dealing with the *Hedychium* for the past few years, and it was in the Theatre of the Royal Society of Arts that it first got to be known. Cultivation was being attempted by different governments in the British Possessions as a result of the first tests that were made, and, to his mind, it was the most promising paper-making fibre of the future, apart from the present fibres that were available, for the production of strong and cheap papers, wrapping, kraft, and so forth, but certainly not for the manufacture of news. The author had referred to the cotton-seed hull, which he (Mr. Clayton Beadle) had under investigation a good many years ago. The cotton-seed hull was a mere waste material up to recent years, one or two million tons of it being burnt every year or dug into the soil, and probably in the British Empire 100,000 tons of cotton had been going to waste every year as a waste product which might be rendered of service in the manufacture of paper and explosives. He went over to Germany many years ago to investigate a process for the removal of fine cotton from the cotton hulls by a process of mechanical separation, but it was a very difficult method to introduce to the paper trade, there being a great deal of opposition to it. It had now, however, become a very important source of material not only to the paper trade, but also in the manufacture of explosives and for similar purposes. That particular product was of interest in another way. If the seed-crushing industry was studied, it would be found that the method of seed-crushing in this country was entirely distinct from that of the United States. In the United States the seed was decorticated, and the hulls were produced as waste products. In this country the seed was crushed whole, and the process of decortication did not come in. It had now been discovered that, instead of taking the hulls and removing the cotton from them by the winnowing process, the whole seed could be passed through a machine, and the

down from the seed, after it had gone through the ginning operation and the lint had been taken off it, could be winnowed off and collected, and that amounted to something like 10 per cent. upon the weight of the seed. That was a very valuable cotton fibre which, when bleached, was of service in the very highest class of paper and for use as explosives, and it fitted in with the method employed in this country for seed-crushing. He thought a good deal more would be heard of that in the future. By a curious coincidence he had only that morning been watching a machine separating the cotton in the above-described manner from Uganda seed, which gave an excellent cotton as a raw material for paper-making, a sample of which he produced. There would be nothing to prevent all Uganda and suchlike seed from being treated in this manner. He believed he was the first to examine the British Columbian spruce, balsam, and hemlock for the purpose of making them into sulphide pulp on a small scale, that is, before it was attempted commercially. The wood was something like 2 ft. in diameter, and he counted rings in it which made it something like 170 years of age. The wood was of uniform good quality in all three cases, and the length and strength of the fibre were equal to those of any sulphide pulp which had been produced in any other country. With reference to the possibility of the utilisation of wood in this country, he hardly considered it a practical question. He remembered that Sir Edward Partington, who was not only one of their greatest paper-makers, but pulp-makers, stated that he thought it would almost pay to take some of the timber in this country and convert it into pulp. Whether he was speaking seriously or not, he (Mr. Clayton Beadle) did not know, but he did not think it was really worth consideration. It had been decided by men who had studied the question seriously that it was hardly within the range of practical politics. With regard to the qualifications of fibre, he quite agreed that almost every fibre was capable of conversion into paper of sorts, but they seemed to begin at the wrong end of the stick somehow or other in investigating a fibre to see whether paper could be made from it. That was only one of the things to be considered; there were all kinds of various qualifications to be borne in mind. The abundance of supply was a very important factor, and if it was a question of cultivating it that almost seemed to him to put the possibility of a cheap supply out of the question. It was necessary to find some part of the world where fibre existed in abundance, where it reproduced itself without cultivation, and could be brought to a port of shipment or to a mill at a very low cost. Some fibres were excellent for the production of paper, but were very bulky, and the question of the freight was therefore of considerable importance. He had recently been dealing with the question of the compression of different fibres in order to get their volume down to dead weight for shipment. It was quite impossible to get some fibres closely packed into bales, and even if one were successful in doing so their qualities were spoiled. Compression beyond a certain point must be avoided, otherwise the fibre was damaged to a very considerable extent as a raw material. Then the question had to be considered of the adaptability of the fibre and so forth for the kind of paper for which it was required. Fibres were now required not so much for high-class papers, but for common papers, in which nine-tenths or more of the raw material was being used. We lived in a country where practically nothing was produced in the way of raw material for the manufacture of paper, so that it was dependent for its supplies on an article which came over the seas from various parts of the Dominion. Taking the British Empire as a whole, he could not help thinking that, in the matter of supplies for the manufacture of paper, it was more self-contained than in almost any other industry, and that there were possibilities of finding raw materials in different parts of the Empire sufficient for its service for several generations to come.

Mr. R. W. Sindall estimated that fifty million trees were being cut down every year for the production of paper pulp. He had had two years' experience in Canada from that point of view, and was surprised to see the careless way in which the forests were treated. The conditions under which the firms were allowed, when he was there, to lease the forests militated against any scientific forestry. He was glad to see the Colonial Governments were now so active in regard to the matter. There were several difficulties in the way in the use of bamboo and fibres other than wood. In the first place, they could only be used for the manufacture of chemical pulp. Fibres were required which could be cheaply converted into a pulp, and, unfortunately, bamboo could not be treated by any mechanical process. Another fancied difficulty connected with bamboo was that frequent cutting injured the stools, so that the plant could not reproduce quickly. There was no certain information on that point, and he strongly recommended the Government of Burma, when he was sent out by the Government of India to investigate the possibilities of bamboo in that country, to look into that question, and see how it affected the reproduction. He believed this point had been satisfactorily settled. Another point connected with bamboo was that many species flowered and then did not reproduce for several years afterwards. A paper-mill dependent for its supply on an area where only one species was growing would find it necessary to take a very long

holiday before the supply could be reproduced. That was, of course, got over quite readily by varying the species. The Queensland Government had sent over to him for investigation a large quantity of prickly pear, and it seemed to him to promise paper of a certain kind. The chief difficulty was to find fibres which could be applied to all varieties of paper. It seemed to him that *bamboo* and *Hedychium* were two promising fibres, and they could be utilised for the manufacture of chemical pulp.

Mr. F. Crosbie Roles said that mention was made in the paper of the latest attempt to produce papyrus pulp on the Upper Nile. He had some quarto stuff in his possession that had arrived during the previous week and was now being tested and valued. It was an advance sample of what was arriving for the first time in bulk in this country. Of course the deciding question was, What it would cost per ton to import into this country? The first commercial shipment of nineteen tons was due on the following day, and another shipment of thirteen tons was on its way from Port Sudan.

The Hon. Sir John McCall, M.D., LL.D., Agent-General for Tasmania, said he was precluded, owing to the record length of the meeting, from dealing with the question of the possibility of the introduction of the paper-making industry into Tasmania. That State had enormous forest areas, much of the timber of which complied with the condition laid down by Mr. Foster—namely, that it must be cheap. A ton of wood cost 25*s*. in Canada and in Tasmania only 5*s*. In conclusion, he desired to propose a cordial vote of thanks to the author for his excellent paper, and at the same time to express, on behalf of the Committee of the Colonial Section, their thanks to Sir George Perley for having occupied the chair.

Mr. Carmichael Thomas seconded the motion, which was carried unanimously; and Mr. Phillips having briefly acknowledged the compliment, the meeting terminated.

Mr. H. A. Bromley, of H.M. Stationery Office, who was prevented from attending the meeting, wrote:—In view of the very serious depletion of the world's forest resources now going on—largely, unfortunately, to supply a demand for purely ephemeral purposes—and the probable steady increases in the rate of depletion, the question either of husbanding our present resources or of finding satisfactory and economical, as well as competitive, substitutes for wood pulp is becoming a very urgent one. In calling attention to the whole question in what will prove an exceedingly interesting paper, Mr. Phillips will, I am sure, be accorded the interest and support of all the paper-making world.

RAILWAY AND INDUSTRIAL SCHEMES IN CHINA.

In the course of his presidential address to the Engineering Society of China, at their recent meeting in Shanghai, Mr. A. C. Clear, M.Inst.C.E., gave some very interesting particulars of recent engineering developments in China.

National Irrigation and Water Conservation.

One of the first and possibly most striking of the developments which have occurred during the last twelve months is the establishment of a National Irrigation and Water Conservation Bureau at Peking. Until the establishment of this bureau any conservation work required was carried out only with regard to local needs. The result was that much patchwork was done. This became every year more difficult to maintain, and almost inevitably failed at the crucial moment, as the almost annual record of floods has proved. The work of the bureau is to centralise and direct local efforts along the lines of a comprehensive scheme, to secure permanent protection, and also to supplement local effort by Government assistance in the case of large programmes.

The scheme which has been brought most prominently to notice is that of the Hwai River Conservancy. By efficient drainage under this proposal some 17,000 square miles of rich agricultural land will be rendered immune from the devastation caused by constantly recurring floods. Many thousands of human beings now so often rendered homeless and devoid of food will, upon the completion of this work, be able to live in comfortable prosperity. Instead of only two harvests in every five years, which is the present low average, bi-annual crops may be expected. In addition, some two to three thousand square miles of low swampy ground, now valueless, will be reclaimed and put under cultivation, giving abundant support to a considerable community. The large sums now expended in charity will be saved, and a contented revenue-producing people should result, providing from their surplus produce food required for other portions of the Republic. Should the scheme prove a feasible one, there would appear to be little doubt about it being carried out, as its magnitude, from an engineering and philanthropic point of view, is such that it will especially appeal to the Red Cross Society of America, which has undertaken to provide the necessary funds.

The canals and waterways of China and their conservation have been a subject of great interest and admiration to all nations, but that admiration has chiefly centred in the past, as the recent neglect of China's waterways is a subject which hardly bears thinking about. Probably in no other branch of engineering does neglect have such disastrous results as in waterways, and where, as in China, the solid matter held in suspension in the water is so considerable the results are proportionately worse owing to the abnormal silting which takes place.

Conservancy engineering has not always been a decadent profession in China, for more than 4,000 years ago a conservancy engineer was called upon to serve as Emperor, as an appreciation of and reward for the inestimable benefits that he had conferred upon mankind. The records state that "The Great Yu" (as the Engineer-Emperor was called) strenuously opposed the honour thrust upon him. It is satisfactory to note that even in such early ages modesty was an attribute of engineers.

North China Oil Fields.

Another step of considerable importance is the decision of the Government to further the development of the natural resources of the country, as evidenced by the agreement entered into in February, 1914, with the Standard Oil Company for the exploitation of the North China oil fields. These oil fields are stated to be of enormous value, and their opening up should be of great financial benefit to the country. The following figures are instructive in this connection. During 1912 the imports of kerosene oil into China from all sources, America, Sumatra, Borneo, Russia, Burma, and Japan (to put them in order of the importance of supply), exceeded 198,000,000 gallons, of a total value of some *Hk. Tls.* 25,000,000.

One can but regret the aversion to the exploitation of her wealth that has handicapped China in taking the necessary steps to open up this vast natural treasure house, if only to supply her people with what they so evidently need. Through the revenue to be obtained from this source alone the economic changes that may be brought about are considerable. The possibility also of building up the export trade which is required to contribute to the financial stability of the country should convince China of the advisability of removing more of the stumbling-blocks impeding her path towards being one of the wealthiest nations in the world.

The mining regulations promulgated by the Chinese Government during the period under review may be considered as another expression of a desire to take advantage of her resources. Mining regulations have been drawn up in the past at frequent intervals, but never have they so closely approximated to what is needed. They are still not altogether satisfactory, being somewhat arbitrary and incomplete, and give evidence of having been effected by those not fitted fully to appreciate the technicalities of the subject.

According to the most recent statistics available the following are the principal metals imported into China during the year 1912:—

	Piculs.	Hk.Tls.
Iron	2,170,000	7,070,000
Copper	122,000	3,529,000
Tin	235,000	2,950,000
Steel	117,000	1,048,000
Lead	105,000	650,000

16·8 piculs = 1 ton. *Hk.Tls.* 1 = 3*s.* 0¾*d.*

Although comparatively little is known of the mineral resources of China, there is sufficient evidence that the metals enumerated above could be found, and found in abundance. The figures given, totalling some 15½ million taels, are instructive, and should assist in firing the imagination towards fuller development, thus bringing many more millions into China's Treasury.

The Coal Industry and Railways.

Another great industry that with modern methods of machinery will tend towards China's prosperity, and of which there is no doubt as to its value, is coal. The output from mines already open is well over 12,000,000 tons per annum, of about £10,000,000 value, the majority of this being used in the country, as only 680,000 tons were exported in 1912, of a total value of £510,000; during the same year 1,500,000 tons were imported, of a total value of £1,215,000.

With the provision of better means of communication and transport, the resources of the country in this direction are practically unlimited. So far, mining development has been considerably hampered by the action of some of the provincial governments in over-taxation, by the antiquated methods of mining adopted in many instances, by lack of means of transport, but principally by the restrictions placed upon foreign capital, without which it is impossible for the heavy initial expenses to be met.

Improved means of transport must first be given, and as these are now being provided through many coal-bearing areas by railways, we should in the near future see vast expansion. Railways loom largely in the development of the country, and at no period in Chinese history have so many agreements for their construction been completed as during last year.

That actual construction has received a temporary setback owing to the European War does not detract from the evident desire of China to open up the country in all directions. This desire has undoubtedly been strengthened by an appreciation of the advantages that were obtained during the recent revolution in the quick transport of troops and munitions of war. Apart from this, there are now sufficient railways in China to convince the most sceptical of their utility and necessity. It is not intended here to discuss all the railways projected during the year, but only those which appear directly to affect the future of Shanghai and for which agreements have been entered into.

The first in order of signature of agreement is the Pukow-Sinyangchow Railway. This, together with the Shanghai-Nanking, the Shanghai-Hangchow-Ningpo, and the Canton-Hankow railways, was included under a concession obtained by the British and Chinese Corporation in 1898, when a preliminary agreement was entered into, upon the understanding that the final terms should await those of the Shanghai-Nanking Railway, and be drawn up similarly. Then followed a long period of delay: first, the Boxer trouble, next the

South African War, later the Russo-Japanese War influencing this, and it was not until July, 1908, that the Shanghai-Nanking Railway Agreement was signed. It was then decided to construct the Tientsin-Pukow Railway before concluding arrangements for this cross-country line, and not until 1902 were negotiations resumed. The agreement was signed on November 14, 1913. The survey is now nearly complete, and construction work had actually commenced when war for the fourth time in this railway's history has put a temporary stop to further constructional work.

The line starts from Wu-I on the Tientsin-Pukow and connects up with Sinyangchow on the Peking-Hankow Railway, a distance of approximately 260 miles. The country traversed is a rich agricultural district with practically no other means of communication or of transport than that supplied by carts, and China carts on Chinese roads are under the best conditions a slow, unsatisfactory and painful means of transport for goods and for passengers. In addition to the heavy grain traffic which must result from this agricultural district, there are considerable coal deposits existing in the near neighbourhood of the line which may be developed to the benefit of the railway, both for its own fuel supply and as an item of freight. There is every possibility that this railway will affect the future of Shanghai, as it opens up a large tract of practically untouched country, with better means of communication across the Yangtsze at Nanking than those at present existing, and facilities for the handling of goods in bulk; a great deal of traffic should find its way into the local markets of Shanghai.

Another very important line is the Nanking-Nanchang-Hunan Railway, which will connect with the Shanghai-Nanking Railway at Nanking and extend through Nanchang, joining the great Canton-Hankow trunk line either through Pingsiang at Chuchow, or possibly direct with Changsha. The line will traverse Anhwei and Kiangsi, provinces rich in agricultural produce and in minerals, particularly in coal. The agreement for this railway was signed on March 31, 1914, and the preliminary survey work has recently been started. The length of main line is approximately 650 miles. From an engineering point of view this line promises to be full of interest.

Important Junction Line.

One small railway which, amongst its mightier brethren, might easily pass without notice, but will be of considerable local importance, is the junction line at present being surveyed between the Shanghai-Nanking and Hangchow-Ningpo railways. This small junction will overcome some of the disadvantages under which the Shanghai-Hangchow-Ningpo Railway is at present labouring, more particularly with regard to the terminal station at Shanghai. This is badly situated from a commercial point of view.

In view of the fact that the present difficulties attending the transport of goods by this route afford a good illustration of similar difficulties to be overcome in the transport of goods from the interior to the coast, a short recital of these may not be uninteresting. From the Yangtsze, through the Poyang Lake and a magnificent series of waterways, runs one of the great trade routes. Water-borne traffic on this route is interrupted at Yu Shan by a range of hills marking the border line of Kiangsi and Chekiang provinces. These hills necessitate a laborious carry-over of some thirty miles to Chang Shan, where boats are again requisitioned to convey the produce another stage upon its journey down the Tsing Tong River to Hangchow. There the trade route diverges to Soochow, Wusih, Shanghai, and other towns.

The great sea-wall which runs unbrokenly from below Hangchow to the sea, whilst forming a barrier to hold the salt water of the Tsing Tong River in check, obtrudes another obstacle to the transport of water-borne cargo proceeding inland. Goods are therefore once more discharged, and, prior to the building of a railway, were loaded again into boats, which literally fought their way through the narrow canals of the city to the more open waters of the Grand Canal. This passage through the city was still further complicated by boats laden with produce, from the towns previously mentioned, coming in the opposite direction. Knowing the "each man for himself" tactics of the Chinese boatmen and the persistent power of his boathook, the wonder is, not that this short journey through the city of seven miles took one month for its accomplishment, but that it was ever accomplished. To obviate this delay a railway was constructed from Zah Kou on the Tsing Tong River to Kon Sen Chiao on the Grand Canal to serve as a carry-over between the two waterways, and is now very fully occupied in the transport of native goods.

The railway known as the Shanghai-Hangkow-Ningpo Railway was connected with this short "carry-over" piece of line, but owing, as previously stated, to the unfortunate position of the Shanghai terminal station, a very small proportion of the goods traffic is rail-borne to Shanghai. The junction line now being built will tend to remedy this objection by bringing the goods into closer touch with the markets of Shanghai.

A short line similar to that from Zah Kou to Kon Sen Chiao is projected on the borders of Chekiang to take the place of the portage from Yu Shan to Chang Shan, and whilst this would be a great improvement on the existing arrangements —which consist principally of mule transport—the continual transfer of goods from boats to trains and *vice versâ* is objectionable. It is slow, costly, and involves a certain amount of loss and damage to the goods with each handling.

It may be asked, what would happen to the boats should they be displaced by railways on these various trade routes? Mr. Clear gave it as his opinion that they will be better off eventually than they have ever been, as they will act as feeders

to the railways, and instead of doing a few long, laborious trips each year, often under heart-breaking conditions, with interminable delays, many short trips could be made that would pay much better. Such a combination of waterways and railways would result in ideal transport facilities. (When the trams were first projected for Shanghai an outcry was raised on behalf of the rickshaw coolies. The trams have come, are filled to overflowing, and there are many more rickshaws in Shanghai than before.) In the process of development the waste that now ensues through constant delays and inability to transport the produce of one portion of the country to another will be avoided, new industries are springing up, and there should eventually be abundance for all.

Developments at Shanghai.

Let us turn now to Shanghai and see what is being done to meet the changing conditions that will inevitably result with improved and extended means of transport. Shanghai is particularly quoted, but much the same could be said of other ports. The following extract, taken from a recent article published in the *North China Daily News*, is peculiarly appropriate and instructive. It is as follows:—

"During the first three months of 1914, 2,394 houses were under construction, a number far in advance of the record for a similar period, viz., 1,350 in the first three months of 1906. It has been estimated that the number of houses erected in Shanghai during 1914 will reach 9,600, but there are indications that this estimate will be exceeded. Many new buildings are being erected for Shanghai industries, and the work marks a further stage in the progress of the settlement towards becoming a big industrial centre. Considerable additions are being made to the mills in the western district, from the French Concession to the Soochow Creek. A Japanese cotton mill is being built on an extensive site at Tong-King and Macao roads, and will probably give employment to some 3,000 work-people. A larger flour mill is in course of construction in the same neighbourhood, and extensive additions are being made to Messrs. Price's candle factory. Lower down the creek towards Markham Road another large flour mill is being built. These works necessitate the building of a great number of Chinese dwellings in their immediate vicinity. Similar activity will be observed at Yangtszepoo. On the War Road extension new godowns and a laboratory are being constructed for Messrs. Voelkel and Schroeder. The Hwa Sing Cotton Company is building a large mill with godowns and store-rooms, and three mills for the cotton company removing from Hong-Kong to Shanghai are being erected on a site off Wetmore Road. In addition to these, considerable extensions are being made to the Ewo Mill premises, and those of the Laou Kung Mow and Heng Foong cotton companies."

From the foregoing it will be seen that local development is going on apace; the Municipal Council is endeavouring by a revision of the building rules to cope with some of the evils that will result from this present rush in building, which is not altogether a subject for congratulation, as the style and quality of the buildings are far from ideal. Behind the garish fronts of semi-foreign buildings great quantities of flimsy houses are being thrown up for human habitation with scant regard to health or safety from fire or epidemic. The recent pamphlet issued by the Engineering Society of China on reinforced concrete should be of invaluable assistance if the results obtained after a long series of experiments were made to apply to buildings generally in Shanghai.

Traffic problems, also, are probably more difficult in Shanghai than in any other town in the world. Already the streets are well-nigh impassable, often dangerous, and to continue to allow the herding of masses of human beings in restricted areas can only result, in the near future, in costly confusion—costly because of the delays and increased risks to persons and vehicles, in the additional wear and tear of roads, necessitating further obstruction to traffic by more frequent renewals to road surfaces, additional police, etc. Underground transport is not practicable in this low-lying, water-logged soil; overhead would be expensive, nerve racking and impracticable, except in the larger thoroughfares. The only solution would appear to be in the provision of wider roads and the limitation of dwelling-houses, particularly in the business quarters. One is tempted strongly to urge a more public spirit than is often displayed in assisting the council to fulfil its difficult obligations in bringing about necessary reforms.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Export Trading.—The announcement of the official desire to do nothing needlessly to obstruct export trading has been gratefully received in textile quarters. In an ordinary year approximately half the export of British manufactures consists of textile goods. Textiles form two-fifths of British exports of all descriptions, and in a time when it is peculiarly important to reduce the adverse trade balance, textile exports deserve especially favourable consideration. It is perhaps none too widely appreciated that the lines of business which allow of the largest and quickest expansion are precisely those in which a large turnover is already done. Those associated with the greater industries of the country have a long-standing acquaintance with the fallacy which assumes that the converse is the case, and that the largest potentialities lie in the neglected and minor opportunities. Transactions in large amounts are evidently wanted in the interests of national finance, and textile export business is distinctively an affair of large amounts. Export is hampered at present by restrictions

which aim at the prevention of supply to enemies, or, in some cases, at the maintenance of a sufficient supply for home needs. The necessity for carefulness in these matters is everywhere admitted, but there are, of course, complaints. Hard cases occur whenever an arbitrary line is drawn, and some have been reported. In all matters necessitating particular inquiry there is delay, and objectionably long waits have had to be borne. For obscure but doubtless valid reasons there have been sudden reversals of official policy, disturbing to traders who thought themselves in safe grooves. Then there have descended upon exporters new edicts issued without warning, and suspected of containing within themselves further seeds of trouble. The upsets have been borne with a calmness that could not have been mustered twelve months ago, but they create a tension which makes the assurances conveyed in the Budget speech especially welcome.

Technical Progress.—The resources of the textile machinists have been laid under contribution by the military authorities, with the consequence that parts of small-arms and other munitions are being made in the works usually devoted to new spindles and looms. More or less, all the makers of mill supplies are busied in one way or another with war materials, and the part played by textile manufacturers in the same connection is already well known. In the circumstances, technical progress cannot be said to be at an end, but its achievements are unobtrusive. The new efforts are not on virgin ground, and aim principally at making goods that somebody else has made before. There is a lull in new discovery, but the world is none the less changing, and the losers from contemporary changes have their wits hard at work. The broad character of some of the goods that will henceforth be wanted more largely can be fairly accurately foretold, and some considerable interest is being taken in alternative methods of working. The spirit of speculative enterprise is anything but dead, and, for the time being, readjustments have more practical moment than new discovery.

The Textile Institute.—Preoccupation with the war gives a sufficient reason for cutting down the spring meeting of the Textile Institute to a one-day sitting. The valedictory address of Sir William E. B. Priestley, M.P., the retiring president, occupied much of the morning session, and an informal address from his successor, Sir William Mather, filled the rest of the time. The head of Mather and Platt, Ltd., makers of so many forms of finishing machinery, is at once a magnate of the textile world and a leader of engineering whose long and world-wide experience ought to be remarkably valuable. The technical papers read were two, including one upon the automatic loom by a member who is himself a builder of looms of the ordinary and the automatic types. In treating of the relative commercial efficiency of the respective machines, Mr. Oscar S. Hall was nothing if not impartial. While his conclusions are far from deciding between the rival claims, they do at least help the observer to appreciate the complexities of the problem.

The Efficiency of Looms.—It is apparent that the advantage offered by any machine is conditioned by the circumstances of its use, which are not the same in all districts or countries. Thus for local causes it may pay handsomely to use in Massachusetts a machine that is not lucrative in Lancashire. The automatic loom, so called because of the arrangements for self-replenishment with weft, is a comparatively expensive contrivance which has to be judged upon its commercial merits. It saves labour, but, in order to make the saving large, certain concessions have to be allowed in its favour. It must be fed with good material, often costing more than yarn that can be satisfactorily woven in the old loom. It must be run slower than the ordinary type, usually about 15 per cent. slower, and the best weavers are needed to work it. The weaver can attend many more automatic than ordinary looms; but the saving does not in all circumstances leave a profit. As is sufficiently shown by the huge preponderance of ordinary looms in use in Lancashire, the old machine is a tough one to beat. Mr. Hall propounded a suggestion that the position of the old loom might be further fortified, and that with stronger weft, lower speed, better weavers and more looms per weaver, it would be made more difficult to oust. The suggestion is one rather for proofs than comments, but it may be observed that the 240-pick cotton loom did not spring into existence fully armed. Looms in past times were run slower than now, and their higher speeding is some sort of proof that the increase was not uneconomical. While it is nothing new for manufacturers to forego small advantages in order to possess themselves of greater ones, there is a certain novelty in Mr. Hall's very thoroughgoing proposition. The experiment is one not difficult to carry out by those owning machines of both types.

American Experience.—The reports in the Miscellaneous Series issued by the Department of Commerce, Washington, although little known in this country, provide matter of interest to observers of contemporary industrial history. They are the work of special agents of the Bureau of Foreign and Domestic Commerce relating to affairs as they present themselves to their eyes, and the scope of the inquiry determines whether they exhibit more than one side of the case. A short paper, "Industrial Conditions

in Montgomery County, Pennsylvania," recites some of the troubles of small manufacturers, without going far beyond their point of view. They have grievances against trade buyers who give out contracts and then refuse to respect them if the market falls. They have a legal remedy but hesitate to take it, for fear of losing further business and of establishing a bad name. They complain also of a system going by the name of "protection," which secures the buyer against any rise in the market between the making of the contract and the date of delivery, and provides that he shall have the benefit of any fall. The complainants are manufacturers of woollen goods and hosiery, and Pennsylvanian makers of hosiery are aggrieved by a form of competition which made itself obnoxious in England at one period. They have to compete with men of no mentionable capital and no business experience, who run their concerns usually at a loss. The conditions are unfavourable, but obviously do not prevent larger and more successful undertakings from springing up, and indeed, one American maker of stockings, whose goods sell in the English market, is credited with a turnover of £1,400,000 a year. Had the report dealt with all sides of the case, it might have been acknowledged that in most divisions of the American textile business contracts are lax. In the last resort these obligations are reciprocal, and the buyer who does not accept finds himself dealing with a supplier who does not deliver, unless it suits his purpose to deliver. The big contract that is placed for the season is talked about and advertised, but hardly believed in by anybody. The recipient uses his judgment upon it, and instead of buying materials to cover it fully buys as much as he thinks the customer will actually take. This laxity is not better than the English firmness, although the results may come to much the same in the end. The explanation of the difference in practice can perhaps be sought in the difference of national temperament. After all, it is not a new discovery that the American customer either wants to buy more than one is inclined to sell, or is opposed to buying anything.

Sewing Silk.—The making of silk sewing-twist by hand survives in Staffordshire, and competent judges recognise in it merits higher than those in twist made by machine. The greater part of the silk thread used for sewing is palpably not neat silk but spun-waste silk, good qualities of which are spun expressly for the Leek trade. Silk sewing-thread is the article prescribed for the seams of army uniforms, and it is apparent that quantities of it have been used by the clothing contractors. On the other hand, members of the Silk Association are not satisfied that cotton has not been used by some sub-contractors, and the attention of the responsible authorities has been directed to this point. The natural increase in the use of silk for sewing has obviously been checked by the introduction of mercerised cotton, and while consumption for this purpose has only a limited importance in respect of quantity the principle involved is a considerable one.

CORRESPONDENCE.

HOUSE-FLIES AND DISEASE.

While an exhibition of apparatus and inventions for the destruction of house-flies and their breeding-places is being held in London, it seems a not inappropriate time to refer to a suggestion of mine which was published in the *Journal* of March 27th, 1914.

The said suggestion was for the exclusion of house-flies from dwellings, and especially from hospitals, for the feasibility of which I gave grounds from my own experience.

At the present time, when wounded and sick men are crowding all available hospitals at the front, the bases, and at home, it seems urgently important that steps should be taken immediately to exclude flies from all hospitals, but especially from those for the wounded, who in many cases are incapable of using their hands to keep the flies out of their eyes.

H. T. Geoghegan.

THE DESIGN AND INDUSTRIES EXHIBITION AT GOLDSMITHS' HALL.

I have to-day had my attention called to an article in the *Journal* of April 9th, regarding the exhibition at Goldsmiths' Hall and the Design and Industries Association.

As a member of the committee I feel that the writer was hardly fair in some of his criticisms, especially seeing the difficulties under which we had to get our little selection of goods together.

It is admitted by those who have seen much of Germany during the last five years that the development of art applied to industry has been little short of astounding. The movement fostered by the Werkbund not only covered fabrics, pottery, printing and articles of everyday use, but all forms of engineering and building, aiming primarily at fitness for use and quality work—the two cries of modern German movement. I should like to recommend your writer to study the last three illustrated year-books of that Society.

Your writer says "the authors of this appeal are artists, they naturally see that the manufacturers have been at fault." This statement is wrong. I certainly cannot claim to be an artist, and the very reason that made me join the committee was that I have found the German capturing the cane trade of the world through intelligent co-operation between designer, trade school and manufacturer, and that I was only able to fight this by using the

same methods. Another of our committee is head of a large furnishing store, a third a furnishing decorator, a fourth an architect, the other three being connected with printing, lithography, and jewellery, both practically and as teachers.

When I see in my own trade, winter by winter large numbers of people on short time while the German has the whole of the export market because of his intelligent use of the artist and trade school, I must say that I feel that every effort in trying to get that same co-operation in this country should receive the whole-hearted support of everyone interested in national welfare.

If your writer will be good enough to get a little more into touch with the Design and Industries Association I think he will see how he has misunderstood our aims.

HARRY PEACH.

Dryad Cane and Metal Works,
St. Nicholas Street, Leicester
May 14th, 1915.

The writer of the article, to whom the foregoing letter has been submitted, replies:—

I regret that my article appears unduly severe to Mr. Peach, but may I be allowed to point out that he seems to have somewhat misunderstood both it and my attitude towards the Design and Industries Association? With the aims of that Association I am in hearty sympathy, and I have already taken steps to put myself in touch with it; but I have seen too much of the working of the Arts and Crafts movement in this country not to feel the necessity for uttering a word of warning.

I am afraid that I cannot claim any knowledge of the cane furniture trade (though I know and appreciate the articles turned out by the Dryad Works), but I have kept in touch with what Germany has been doing in other industries, and I am not convinced that the success of her export trade has been due more to the artistic quality of her work than to its cheapness. That is not an argument against any attempt to improve the taste of our own output, but it is one against expecting an immediate and remunerative response on any very large scale to the efforts which may be made.

Again, if your correspondent will refer to my article, he will see that in the quotation which I made from "Design and Industry" the world at large is divided into three classes—designers, manufacturers, and the purchasing public. I was not aware that Mr. Peach was a manufacturer, and I am sorry that I put him into the wrong compartment; but I think that even on his own showing the other members of his committee do not, for the most part—in such a classification—come under the heading of either manufacturers or the purchasing public. Perhaps as a manufacturer he has been accustomed to use the word "artist" in a more limited sense than is possible to anyone who has always been in close touch with artistic craftsmen.

NOTES ON BOOKS.

VILLAGE AND TOWN LIFE IN CHINA. By Y. K. Leong, LL.B., B.Sc. (Econ.), and L. K. Tao, B.Sc. (Econ.). London: George Allen & Unwin, Ltd. 5*s*. net.

For all students of sociology this book possesses very considerable interest. It is a work about certain aspects of life in China by two Chinese students, who, while they have been familiar from their birth with what they describe, have also been for some years students at the London School of Economics and have thereby been enabled to apply themselves with quite unusual opportunities to the comparative study of widely differing social institutions.

The first part, which is by Mr. Leong, describes the village life—the family, the clan and the village society. Mr. Tao's section deals with town administration and social life, and with the popular side of Chinese Buddhism. In both we see the family as the great unit, including the ancestors, all the living kindred, and the unborn members who are to perpetuate the memory of their forefathers. The real China emerges not as a despotism, but as a great aggregate of democratic communities, governing their affairs through the heads of families. The authors throw a good deal of new light on the real meaning of this family life. They emphasise its ethical value, and the spirit of self-sacrifice on which it is founded; and they also point out how much it has done practically to provide for the old, the poor and the helpless.

One of the most interesting points dealt with in the book is the position of woman in China. According to these writers, she really holds a position of authority and respect, qualified only by a technical inferiority of position. If the education of Chinese girls (as we understand the word) usually ceases at an earlier age than that of the boys, it is because the Chinese consider their special training better adapted to the potential mothers of families. A Chinese girl can manage a family at an age when a Western girl is still at school. If her powers of reading and writing are small, it does not follow that her knowledge of literature is limited. It is a common recreation for women to listen, as they work at embroidery, weaving and so forth, to minstrels who sing them the classics of Chinese poetry, romances, legends and chronicles, "and very often when no minstrels are at hand they each sing in turn, and all from memory. As they generally cannot read, their powers of memory are marvellously developed. It is quite an ordinary thing for a girl to repeat from memory word for word a poetical legend of several thousand lines after having heard it but several times. I wonder whether an average factory girl in England would be able to recite off-hand a stanza from Shakespeare or any other poet."

For a system of education which gives such results as these there must be a good deal to be said; but one may, perhaps, be permitted to doubt some of its advantages when one learns that "on the marriage or death of relatives and friends she has to recite extempore appropriate verses of her own on such subjects as the sorrows and joys of life, the virtues of filial piety, friendship, and so on." Unless on these occasions she can borrow very freely from her memory of the classic poets, it is to be feared that her efforts will prove somewhat tedious.

LITHOGRAPHY AND LITHOGRAPHERS. Some Chapters in the History of the Art by Elizabeth Robins Pennell, together with Descriptions and Technical Explanations of Modern Artistic Methods by Joseph Pennell, President of the Senefelder Club. London: T. Fisher Unwin. 10*s.* 6*d.* net.

The art of lithography was invented by Aloys Senefelder in 1798. In 1819 the Society of Arts awarded him a gold medal "for having freely communicated to the public the most perfect and complete account of the whole process of Lithography, of which he is the inventor." Mr. and Mrs. Pennell put it on record that the gold medal was promptly pawned, but Senefelder must have appreciated the Society's recognition more than this action might seem to indicate, for he presented them with one of his printing presses in acknowledgment of their award. It is seldom that the early history of an invention can be so shortly and so certainly stated. There have been others who tried to get credit for the invention, but the researches of Mr. and Mrs. Pennell have established the claims of Senefelder beyond any shadow of doubt whatever.

The first part of this book, which deals with the history of the art, is the work of Mrs. Pennell. It is founded on the well-known book of the same authors, which was issued in 1898, and has long been out of print; but it contains a great deal of fresh material, and has been entirely rewritten. Much of the information contained in it was embodied in the admirable course of Cantor Lectures on Lithography which Mr. Pennell delivered before the Royal Society of Arts last year, but, of course, the book is very much fuller and more complete in every way.

The second part of the book, which is the work of Mr. Pennell, is entirely new. It explains in a singularly lucid way the various technical processes in the art of lithography. For many years lithography was wrapped in mystery, and secret processes were the rule, but here all is explained by Mr. Pennell, and there is found to be no black magic about it. "Now that we have solved these mysteries," he says, "we find they were mostly made up of lemon-juice, labour leagues, stale beer, and hide-bound stupidity, and we have either found out the secrets, or other printers, other methods, or set up presses of our own."

There can be no doubt of the enormous gain to lithography from these modern, enlightened methods. After languishing in an almost moribund condition for some thirty years, the art began to revive at the opening of this century, and each year sees steady and enormous improvement. At the present moment many of our finest artists work in lithography, and the wonderful changes which the last few years have shown on our advertisement hoardings are the fruit of this development. Probably no one has been to a larger extent responsible for this advance than Mr. Pennell. An enthusiastic lithographer himself, he has shown what the art can do in the hands of an artist, and the Senefelder Club, of which he is the president and the ruling spirit, is rapidly teaching the world to appreciate the possibilities of lithography. There can be no doubt that this book, which is extremely readable and lavishly illustrated with reproductions of a very large number of lithographs, will do much to foster the interest in what can be, and ought to be, a highly artistic art.

VALUATIONS. By Samuel Skrimshire, F.S.I. London: E. & F. N. Spon, Ltd. 10*s.* 6*d.* net.

This text-book deals with valuation as applied to the sale of property (freehold, lifehold, copyhold, and leasehold), assessments to duties under the Finance (1909-10) Act, the enfranchisement of copyhold estate, assessments for rating purposes, compensation on compulsory purchase, and valuations for advances on mortgage. The subject is a very complicated one, and there is practically no limit to the knowledge which an expert valuer ought to possess. He certainly should be well-informed on such points as building and sanitation; he may well be required to estimate the value of timber growing on a property, or of minerals which may lie beneath it; he must know the value of neighbouring properties, and in many branches of law he must have an expert's knowledge. It is obvious that no single book could deal with all the subjects on which a valuer may be called upon to give an opinion, but as regards those which are laid down by the Surveyors' Institution for examinations which their members must pass, this volume should prove a very useful guide. It is clear and succinct, and the large number of practical examples which are worked out for the student should enable him to obtain a firm grasp of the various complicated problems presented to him.

GENERAL NOTES.

TRANSFERRING WORKERS TO A NEW TRADE.—An article in the *British Review* records an interesting experiment recently made at Toynbee Hall "to take mature men, mostly over the age of forty, and teach them a new trade." The

furniture trade, being hard hit by the war, was suffering from a glut of workers. The leather trade was experiencing an unprecedented scarcity of hands, owing to the insatiable demand for leather stitchers for military accoutrement work for the British, French, and Russian Governments. Some of the residents at Toynbee Hall hit on the brilliant idea of deliberately transferring men from one trade to the other. The Prince of Wales's Fund produced the money needed to equip the school and maintain the scholars, and the school was opened on December 7th. It was a venture of faith, but faith was more than justified. Out of 139 scholars enrolled up to January 15th, only two men were sent away from the school because of their inability to learn a new trade, and fifteen left because they had got work at their old trade. Every man who has had a full month's training at the school has found work, while some of the men have got good regular work after a fortnight. The average wages earned by the men who have found work are between 30*s.* and 35*s.* Some are earning £2 a week, and a few as much as £3.

Proposed Military Academy at Quetta.—The *Civil and Military Gazette* understands that the Government of India propose to establish shortly a military academy at Quetta, to be founded very largely on the lines of the Royal Military College at Sandhurst. A number of young officers have arrived, or are arriving, in India for appointment to the Indian Army after passing the qualifying examination at home. These young officers will be called on to pass a further examination at the end of six months, which period they will pass at Quetta, at the above military college, where they will learn their duties and generally qualify themselves for employment in the Indian Army. The details of the scheme and the staffing of the college are now engaging the attention of the military authorities.

Industrial Activity in Switzerland.—There appears to be considerable activity in many branches of industry, at the present time, especially in the canton of Soleure. The metallurgical establishments are working overtime in consequence of the numerous orders which are coming in from abroad. At Olten, the boot and shoe factories, as well as the motor-car factories, are in full work. The watchmaking industry, which last summer was nearly at a standstill, has now resumed its former activity, in consequence of the numerous foreign orders which are coming in daily.

Traffic on the Suez Canal in War Time.—The statistics published by the Suez Canal Company for 1914, whilst showing an increase of nearly 2 million francs (£80,000) in the receipts for the first half year, indicate a decrease of about 6 million francs (£240,000) in those of the second half-year's workings. As compared with 1913, this shows a falling off of 4 million francs (£160,000). This, on a total of 121 million francs (£4,840,000) annually, is not very considerable, but it must be taken into consideration that the receipts of 1912 had already shown a decline of 12½ million francs (half a million sterling) against those of the previous year. The transit of the troopships from India *viâ* the Canal last autumn no doubt prevented the receipts from falling lower. It is to be feared that, judging from the decline in the tonnage that passed through the Canal last January, a still further decline in the traffic returns may be anticipated during the present half year.

MEETINGS FOR THE ENSUING WEEK.

Tuesday, May 25...Royal Institution, Albemarle-street, W., 3 p.m. Dr. M. O. Forster, "Colouring Matters of the Organic World. Lecture II.—Dyes: the Creation of the Chemist."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. R. I. Pocock, (*a*) Exhibition of pieces of Wild Boar skin; (*b*) Exhibition showing evolution of Porcupines' quills. 2. Mr. S. Hirst, "On a Blood-sucking Gamasid Mite parasitic on Couper's Snake." 3. Mr. G. A. Boulenger, "A List of the Snakes of Madagascar, Comoro, Mascarenes, and Seychelles." 4. Dr. P. Chalmers Mitchell, "Anatomical Notes on the Gruiform Birds *Aramus giganteus* Bonap. and *Rhinochetus kagu.*"

Wednesday, May 26...Literature, Royal Society of, 20, Hanover-square, W., 5 p.m. The Very Rev. the Dean of St. Paul's, "English Religious Poetry."

Thursday, May 27...Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Annual General Meeting. Review of the work of the Session by the President.

Friday, May 28...Petroleum Technologists, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. H. Barringer, "The Evolution of the Oil-Tank Ship."

Royal Institution, Albemarle-street, W., 9 p.m. Sir John Jackson, "Engineering Problems of Mesopotamia and Euphrates Valley."

Sanitary Institute, Guildhall, Shrewsbury, 7.30 p.m. Dr. T. Orr, "The Value of Mechanical Filters in the Purification of Water."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Saturday, May 29...Linnean Society, Burlington House, W., 3 p.m. Anniversary Meeting.

Royal Institution, Albemarle-street, W., 3 p.m. Professor R. S. Rait, "Mary, Queen of Scots." (Lecture I.)

Correction.—Mr. Charles R. Darling asks that the following correction be made in his paper on "Recent Progress in Pyrometry," which was reported in the last issue of the *Journal*: The pyrometer described as "Becker's" on pp. 597, 598 and 599 of the *Journal* was designed in the Research Laboratory of the Rudge-Whitworth Company, Coventry, and should have been designated the "Rudge-Whitworth Pyrometer."

Journal of the Royal Society of Arts.

No. 3,262. VOL. LXIII.

FRIDAY, MAY 28, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, May 13th, 1915; The Most Hon. the Marquess of Crewe, K.G., P.C., Secretary of State for India, in the chair.

The Chairman, in introducing the reader of the paper, said Sir Charles Armstrong's experience enabled him to deal to the fullest extent with the subject of the paper. Sir Charles had had a long experience in India, dating from the year 1885. During that time Sir Charles had filled many prominent offices in connection with different activities in Bombay, culminating in the extremely important Chairmanship of the Chamber of Commerce of that mighty commercial centre. Those facts alone would entitle Sir Charles to speak on the subject of the paper, but, in addition, Sir Charles had been for a considerable period a member of the Legislative Council in the Presidency of Bombay, and for a somewhat shorter period a member of the Viceroy's Legislative Council. That double distinction was of importance in the following respect: India was so vast and so various, that those who were only acquainted with the circumstances of one division of the Indian Empire were at any rate liable, as the phrase went, "not to see the wood for the trees." On the other hand, those, fewer in number, who had only had the opportunity of examining India from the centre, were likely to fall into the opposite defect—to be so much impressed by the magnitude of the area of the forest as not to pay due attention to the precise vegetation of which it was composed. From either of these temptations a man like Sir Charles Armstrong, who had served in the Legislative Council both of a Presidency and of the central Government, was likely to be secure.

The paper read was—

INDIAN TRADE AND THE WAR.

By Sir Charles H. Armstrong,

Late Chairman of the Bombay Chamber of Commerce.

My paper this afternoon is on "Indian Trade and the War," and, so far as Indian trade is concerned, a great deal of much interest could, no doubt, be said; but as my time is limited I will not attempt too much, and will only, therefore, touch very briefly on the early history of India's external or foreign trade, so that I may be able to deal at greater length with the trade conditions of the present day. I shall then have something to say about the railways in India—their administration and so forth—and later on, towards the end of the paper, I shall refer to the effects of this great and terrible war on the sea-borne or foreign trade of the country. I trust that in the course of my remarks I shall be able to convey to you a correct impression of the vastness of India's oversea trade and of its great importance to the markets of the world, for India is a keen buyer or seller—and sometimes both—in all great commercial centres. As we proceed, you will see how rapidly the sea-borne trade has increased in recent years, the reasons for this increase, and the great possibilities of the future.

With these few introductory remarks I will now proceed to the reading of my paper, which I trust will be found interesting, but the subject is not one that lends itself to very attractive treatment.

We may, I think, accept as a fact without comment that India's internal trade must always have been of considerable importance, although hampered in early days by many difficulties and restrictions, but the foreign or sea-borne trade has only become of great value in comparatively recent years. In very early days there was a land connection between the Caspian or Black Sea and the western districts of Hindustan; but in the seventh century B.C. a sea trade sprang up between the Persian Gulf and India, and from the head of the Gulf caravans carried supplies into Syria and Egypt. Later on, in about the first century A.D., the Red Sea route was developed, and by slow degrees the trade spread gradually into Eastern Europe. With the arrival of the Portuguese in Southern India in the fifteenth century the

foreign trade was organised and developed, and regular shipments were made to Antwerp—at that time the commercial centre of Europe. Towards the end of the sixteenth century, an English company began to trade with India, and in the year 1600, or only a little over 300 years ago, the first English East India Company was founded. The foreign trade at that time, and for some time later, was very small, and it was not until the end of the eighteenth century that the shipments increased to a considerable extent. The difficulties that had to be contended with in those days were the long sea journey to Europe *viâ* the Cape and the great difficulty of bringing produce down to the coast from the interior of the country, as there were no railways, and the means of transport, excepting where there were navigable rivers, were very primitive. At the time of the Mutiny, or, say, fifty-eight years ago, there were only about 270 miles of railways in India, one section being under construction inland from Calcutta and another from Bombay, and it was largely due to the difficulties then encountered that a development of the Indian railway system was brought about. The great event for India, so far as its foreign trade is concerned, was, however, the opening of the Suez Canal in 1869, which reduced the voyage to Bombay from 100 days or more to about twenty-five days, and this great change brought about a most striking development in trade.

Now, in dealing with this subject it is necessary to bear in mind that India will always be mainly an agricultural country, and that the prosperity of the people will depend upon the annual rainfall. It must be very difficult for those who have never been in the East to realise the supreme importance to the country of the monsoon rainfall, which sets in on the western coast at the end of May or early in June, and, after spreading rapidly nearly all over the country, continues in these parts until the end of September, and in some parts—more particularly on the Madras coast—until about the end of the year. In addition to the south-west and north-east monsoons, to which I have just referred, there are, in Northern India, the cold-weather rains in January and February—only a few inches it is true, but sufficient, nevertheless, to produce some of India's most valuable crops on which the prosperity of the sea-borne trade very largely depends. The drawing up of the Indian Budget, which is presented to the Imperial Legislative Council in Delhi early in March was described only a few years ago by the Financial Member as being a "gamble in rain," and it can well, therefore, be understood that the coming of the monsoon in June, and its progress during the four months June to September, is anxiously watched, not only by the officials of Government, but by the commercial community and the agriculturists whose livelihood and prosperity depend on a successful harvesting of the crops. Before the advent of the rains the country is parched and dry, and the cattle in many districts have to seek for water at long distances. With the coming of the monsoon, however, and the commencement is generally very heavy—I have known, for instance, 24 in. of rain to fall in Bombay in three days—conditions change very rapidly; the country is covered with new grass, and there is any amount of water in the fields, tanks and wells. In about five months the first crops are reaped, and preparations in many parts of the country are made about this time for sowing the winter crops in the damp land, and these mature in the early months of the year. A bountiful rainfall is of inestimable value, but an absolutely perfect monsoon is very rare, and although in my long experience of thirty years I can remember many good monsoons, I can only call to mind one that was really perfect, and that was two years ago, in 1913, when magnificent crops were reaped on all sides. A difficulty in India is that, whereas some crops thrive best with a light or moderate rainfall, others require a fairly heavy downpour, and it is rarely that the fall in the different districts is just sufficient—neither too much nor too little—for the needs of agriculture. It has been said that a few inches of rain, if properly distributed, will produce a perfect cotton crop, but this would not, by any means, be sufficient for the food grains grown in the monsoon, which are used mainly for feeding the people of India. There can be no doubt, however, that, apart from trade matters, bountiful crops are of the greatest value to India, for when there is ample work for everybody, when wages rule high, and when food grains are cheap, the people are prosperous, happy, and contented; whereas, when the reverse is the case, there is poverty and discontent, and this leads to trouble of various kinds, and makes the people more ready to believe that the Government are responsible in some way for their troubles, and it sometimes leads them to take steps to ventilate their grievances. A famine in India on a large scale is always very awful, and after the monsoons there is often, in some part of the country, an area of scarcity

where provision has to be made by relief works and in other ways to provide for the people until the coming of the next rains, which is, of course, many months ahead. There have been several severe famines during my time in India, but one of the worst was not so much a food famine—for now the country has been opened up by railways, supplies of food can be rapidly imported into a distressed area—but a scarcity of water on a large scale due to a very short and absolutely deficient rainfall. This failure of the monsoon caused the most acute misery during the hot weather months, and although everything was done that could be done, many lives were lost and the cattle died also or had to be slaughtered in very large numbers. The conditions, however, under which a food famine is now dealt with are very different from those which used to prevail, for in the great Madras famine of 1876, when many millions of people died, there was an ample supply of rice in the city of Madras, which had been imported from Burma, and there was also a surplus stock available from the Central Provinces, but these supplies, to a great extent, could not be distributed in the districts of the Madras Presidency owing to insufficient means of transport, and in many cases, even when they did reach the starving people it was found, unfortunately, that in their weakened state they could not digest a rice they had not been accustomed to. The extension of railways in recent years has, however, greatly improved matters, and although from time to time there will always be famines in various parts of the country, the loss of life is never likely to be anything like what it was, for the Government system of immediate relief has now been organised on sound lines, and the effects on trade, although serious, will never be felt to the same extent as in the past.

The chief exportable crops produced in India are jute and tea in the east, *i.e.*, on the Bengal side; cotton in various parts of the country, but mainly on the Bombay or western side of India; rice in many districts over an area of 76,000,000 acres; wheat mainly in Northern and Central India; and oilseeds of various kinds, the principal being linseed, rapeseed, cotton-seed, and castor-seed. The export of raw and also of manufactured jute—for Calcutta has many mills working up the raw material into gunny bags and cloth—is the largest foreign trade, but raw cotton is also a very valuable crop, and one that is likely to increase steadily in value and in quantity. The exports of wheat vary with the seasons, and with the demand for Indian supplies from the markets of the world—this country, amongst others, being a large buyer. In the production of jute India is fortunate in having a monopoly of supply, and in tea also her position is a very strong one, but in the other articles I have referred to the prices India is able to obtain in distant markets are regulated to a great extent by the supplies obtainable from other countries—mainly from North and South America and from Canada—and the money received in return is governed, therefore, by what are known as "world's prices." In cotton, for instance, the export price is regulated to a great extent by the crop grown in the United States of America, which is the world's bumper crop, and the ryot or agriculturist in India receives, therefore, varying prices for the produce of the soil according to the position of the world's markets. The monsoon of 1913, to which I have already referred, produced the finest cotton crop, not only in quantity but in quality, that India had ever grown (in quantity it may, however, be exceeded this year), and, most fortunately, satisfactory prices were realised for it. The demand for Indian cotton comes from various countries. Japan is a large and persistent buyer for her mills, and several countries in Europe take also very large quantities—notably Germany, Austria, France, and Italy.

For many years, although it is some time ago, Lancashire—the great centre in this country of cotton spinning and weaving—was a good buyer of Indian cotton, the shipments in the early seventies having been over 1¼ million bales, or more than one-half the total crop; but from this date, owing to the superior attraction of supplies from America, the trade fell off very rapidly, until in 1911–12 the Indian shipments to the United Kingdom were only 50,000 bales out of a total crop of over four millions. Since then, however, the trade has revived a little, and it is possible that importations into this country will increase in the near future. The growth of the cotton-mill industry in India has, however, checked to some extent the exports of the raw material, as just over two million bales are required for this purpose in the country itself, and as Japan is also a very keen buyer the trade to Europe is, perhaps, inclined to fall off. In the year ending June 30th, 1912, the shipments to the United Kingdom and to the Continent dropped to 736,000 bales against a total exportation from all India of 1,828,000 bales.

This, however, was an exceptionally low figure to Europe—about 50 per cent. less, in fact, than in the previous year, when from the port of Bombay alone over a million bales were shipped to this country and to the Continent, the total shipments from all ports having been 1½ million bales. Japan has become a great competitor in recent years, and as the mills in India will absorb increasing quantities, there will not, in future, be as much available for export to Europe, unless the crop can be materially increased. An increase in the area under cotton, which is now 24½ million acres, and a further increase in the yield per acre, are questions which have been prominently before the Government of India and the commercial community for some time past, and steps have lately been taken by seed selection and in other ways to improve the type of cotton grown and to add to the yield. Some success has already been achieved, and if the Government of India will steadily persevere in their efforts, and this they are likely to do, their reward is certain to come in time, although progress at first may be rather slow. If Lancashire can be induced to interest itself again in supplies from India, and it looks very much as if a satisfactory start in this direction has already been made, there is a great opening for increased trade; but quality or length of staple is an important factor, and this is a question which will always have to be kept well to the front. But even if this country does not become an active buyer, there will always be eager markets for all the cotton India can produce, and with the growth of the Indian mill industry there may be less available for the markets of the world. The question of cotton cultivation and of the improvement of the staple is an extremely important one, which should not be lost sight of. As for raw jute, Calcutta, as I have said, has a monopoly, and the trade, consequently, is a prosperous one. Indian tea is, of course, well known and much appreciated in this country, although, personally, I prefer Ceylon; but the trade is a growing one, and at the present time is very profitable. Calcutta is indeed fortunate in having two such valuable crops. The wheat area is immense, about 30 million acres—this year over 32 millions—and the outturn roughly speaking is 10 million tons; but only a small part of this, 12 to 15 per cent., and less when the crop is smaller, is available for shipment to foreign ports, the remainder being consumed or stored in the country. The excess supply, however, is very valuable, and the go-ahead port of Karachi is the principal place of export.

There are, as I have already mentioned, other important exports, for instance: cotton goods and yarns, which go mainly to China, the Persian Gulf, and other adjacent markets; wool, mainly from Karachi; manganese ore, chiefly from Bombay (a growing trade, although under a cloud at the moment owing to the war), and many other articles of considerable amount, which in 1913–14, when added together, gave a total value, including a small amount of re-exports of foreign goods, of £166,000,000 sterling, against a quinquennial average 1864–5 to 1868–9 of 54¾ millions, and in the year 1904–5 of 105 millions; so you will see the trade is growing steadily and is certain to increase. This huge export trade brings with it a corresponding increase in imports, the principal articles being cotton manufactures of all kinds, which come almost entirely from this country and were valued last year at over 44 millions sterling; metals and metalwork of various kinds; sugar, of which the people of India are very fond; railway plant and rolling-stock; machinery, oils, and many other articles of great importance, which in 1913–14, when added together, gave a total value, including Government stores, of 128 millions sterling. The growth of the import trade has also been very satisfactory, the figure I have just named comparing with an average of £30 millions in the five years 1864–5 to 1868–69, and with £70 millions in 1904–05. There is immense scope in India for an increased trade in imports, and as the foreign export trade expands the demand for manufactured goods from this country must also increase. Wealth is steadily, if not rapidly, accumulating in India, for the people are frugal in their habits, and, generally speaking, are content with very little; but even so, as their wealth increases their needs also increase, and an extra dhooty or sarrie is always a welcome addition to their scanty stock of clothing. The average wage for the bulk of the people is small, very small indeed when judged by our standards; but as their wants are few nearly everyone has something to fall back upon, either in the shape of land, jewellery or buried coin. I do not say that this amounts to much individually, although the women folk in many parts of the country are covered with silver bangles on their arms and legs, in their ears, and sometimes through the nose; but in the aggregate it comes to a large sum, and throughout the country there is, therefore, an

immense amount of unproductive wealth. To get at these hoards, and to bring this hidden treasure into profitable use is one of the great problems of the present day, and there are signs in quite recent years that the efforts now being made in this direction are not altogether in vain.

From the figures I have given you will have seen that the balance of trade, *i.e.*, the excess of exports over imports, is greatly in India's favour, and the account is partly squared by large imports of the precious metals, gold and silver in the shape of sovereigns and bars, a large part of the silver being often for coinage into rupees, which is the standard coin of the country and is worth, when measured in gold, sixteen pence against an actual value of metal of something much nearer a shilling. The currency system of India is, however, on a sound basis, and later on I shall have something to say regarding it, but this remark of mine must not be understood as passing judgment or as referring in any way to the controversial questions raised before the Finance and Currency Commission which sat in London a little over a year ago. India, however, is largely indebted to England for money borrowed to build railways and to construct irrigation and other productive works. There are also large annual payments to be made to this country for necessary charges of administration, and the excess of exports enables the country to pay its way in both respects, and to add, besides, a large amount to the savings of the people. The account is finally adjusted through the instrumentality of the Secretary of State, who sells drafts on India during the year for many millions sterling; but the system is one I need not explain in detail.

The net annual imports of gold in recent years have averaged about 20 millions sterling, and as the foreign export trade increases this figure will also increase. To anyone travelling through India the immense wealth of the country is not, perhaps, immediately apparent, but the area is of such vast extent, and the population so large—about 315 millions altogether—that production on a large scale is inevitable. The land in good seasons is very fertile, the soil in many districts is rich and retains the moisture, and the crops, although often rather scanty to the eye, are, on the whole, very prolific. An immense amount of the produce of the soil is consumed by the Indians themselves, and the quantity of food grains exported is probably only a small percentage, but even so, the whole foreign trade—imports and exports—is very large, although per head of the population of 315 millions it only works out at 17*s.* 7*d.* against £25 15*s.* per head in the United Kingdom, whose population is 45 millions—an immense difference, which should, however, be reduced in the years to come as the country grows richer. There are great possibilities in Indian trade, and as the exports increase—raw materials as well as manufactured goods—the imports will also increase. Although in a hot country much clothing is not required, the people in India seem inclined to wear more and better garments as they increase in wealth. Amongst the poorer classes food is the first consideration, and, generally speaking, it is only the surplus wealth that is spent on extra clothing and on other imported articles. As a matter of fact, however, a woman of the working classes can deck herself out almost in the height of fashion for the modest sum of 3*s.* or 3*s.* 6*d.* with a bright-coloured sarry which she wraps round her body and then brings over the head, and with two other small garments in addition, all being made of cotton. A man of the same class can also clothe himself for the same sum with nine yards of bleached cloth wrapped round his head for a puggaree, a dhooty of five yards or so wrapped round the lower part of the body and brought up between the legs, and above this a small cotton jacket. These garments are also made of cotton, and will wash, so, if the wardrobe is small and there is no change of clothing, the wearer has only to wait until the scorching sun has dried the only garment he or she possesses.

The women folk of India love bright clothing, which, in the sunshine, looks very picturesque, and as, no doubt, they like to have a good selection of sarries, the demand for printed and dyed goods is always greatly stimulated after a good harvest, when the people have a little surplus money at their disposal. The cotton goods imported into India come almost entirely from this country, as I shall show later on, but Bombay is now a great manufacturing centre, and there are also many spinning and weaving mills in other parts of India. On August 31st last year there were 84 cotton-mills in Bombay Island and 92 more in the Presidency, a total, with seven in course of erection, of 183 against 271 for the whole of India, so Bombay City and Presidency have the lion's share of the trade. The industry, generally speaking, is a prosperous one, and now that looms are being turned on to different classes of goods there is a great future before the trade. Formerly, the production in Bombay was mainly yarns for

export to China, but now that this trade is falling off owing to the competition of the Japanese mills, Bombay spinners in many cases have added looms to their factories, and are now largely engaged in manufacturing cloth for local consumption. In some directions this interferes with an increase in the importations from Lancashire, but as the people grow richer they will want more and more of the better-class goods produced in this country, and we need, therefore, have no fear for the future of our trade. It is interesting to note in this connection that, whereas in the whole of India there were only 47 cotton mills in 1876, there are now 271, employing 260,000 hands and consuming over 2,100,000 bales of cotton. For the sake of comparison, I may mention that there are over 2,000 cotton-mills in this country employing, however, only 650,000 hands, and I may also add that England, helped by her free trade system, has far and away the largest export trade in the world in cotton fabrics, as she is able to produce on exceptionally favourable terms.

The fiscal system of India is also free trade, and under it the country has undoubtedly prospered. There is, it is true, a tariff not exceeding 5 per cent. on imported merchandise, but this is for revenue purposes only, and, whereas in the case of manufactured cotton cloth there was competition between India and England, a countervailing excise duty was imposed on cloth made in power-looms in India for consumption in the country. After jute manufactures, the cotton industry is the most important, and there is a great future in store for both these trades.

The distribution of India's vast trade in merchandise is a very interesting study, but the bulk of it is with the United Kingdom. The produce exported passes through many hands before it reaches the consumer, but the cost is not added to very materially by this, as Indian trade generally is worked for a very narrow margin of profit. The Indian himself is a born trader, and his powers of bargaining are proverbial. The son follows the father in his trade, and begins to take an interest in the business very early in life. Many businesses are carried on as joint family properties, in which all the members, including the women folk, have a share, and, no doubt, the object of this arrangement is to keep the wealth in the family. The people themselves are very thrifty, and, as I have said, nearly all of them have something laid by—a bit of land in some part of the country to which they will retire in old age, or jewellery for their women folk of gold, silver or precious stones—the latter amongst the wealthier classes being sometimes of great value. They are a shrewd people and know very well the value of what they have to buy and sell. The land is cultivated by many millions of the people, only a very small percentage being employed on manufactured goods, and the exportable crops are very often sold to middlemen or merchants before they are grown, and sometimes even before they are planted. At the time of harvest the produce is collected and sent down in due course to one of the large seaport towns, where it is stowed away in steamers for its destination in Europe or elsewhere. Imports from England and other countries are received by the merchants at the ports, and, after passing through the hands of the wholesale dealers, find their way into small retail shops in the districts or are hawked round the country by an army of travellers. A cloth bazaar in India is a gay sight, and, excepting just at the time of the heaviest rains, there is always an active retail trade going on.

Coming now to figures. The imports of merchandise into India from the United Kingdom alone for the year ending March 31st, 1914, were valued at 78 millions sterling, and from British Possessions and colonies at about 7 millions, a total for the British Empire of over 85 millions sterling out of a total value from all countries of 122 millions, so you will see from this what a very important market India is for Great Britain, her colonies and possessions. From all other countries the total imports a year ago were valued at 37 millions sterling—an important trade, no doubt, and one that will grow, but the British Empire has the lion's share of the import trade, and this she is likely to retain. The supplies from other countries are, in some cases, articles necessary for India which are not produced in quantity in the British Empire, and this trade will continue. Amongst foreign countries Germany has, or had, the largest import trade with India, but many articles which have lately been imported from Germany will now, I think, be made in this country. One very important supply from Germany is aniline dyes, which, I hope, will now be produced in much larger quantities in Great Britain, and if the scheme now being worked out is a success, I trust these English dyes will be put on the Indian market, and that the trade will be pushed in every way possible, for it is very important that India should not be dependent

on Germany for her dyes, and if a change is to be made the trade should come to Great Britain. Great credit is due to the British Government for recognising the importance of this new departure, and for pushing the matter on so successfully against many difficulties, and if the scheme is a success, as I hope it may be, the position of producers of textiles and other goods in the British Empire will be greatly strengthened. To sum up, England last year had 64·1 per cent. of the Indian import trade, foreign countries 30 per cent., and our colonies the remainder. The position as regards exports is, however, very different; the share of this country is only 23·7 per cent., foreign countries 62·2 per cent., and our colonies the remainder, or, say, 13·9 per cent., and it was this fact that influenced Lord Curzon's Government to adhere to India's fiscal system of free trade; for, by a change in the opposite direction there was little to gain and possibly a good deal to lose. I have always felt that in the great controversy of Free Trade or Protection—which is now, perhaps, ended—the important position of India as a part of the British Empire was, to some extent, lost sight of, and that at one time her interests were likely to be sacrificed or subordinated to the colonies. All I wish to say at the present time is, that if the matter ever does come up again for serious discussion, India should always be thoroughly represented, and the immense volume of her foreign trade and its great importance to the people of India should never be lost sight of.

After Great Britain, Germany is, or was, India's most important customer, and then follow Japan, the United States, France, and other countries. The trade with the United Kingdom is mainly in raw jute, tea, and wheat, but importations of other articles are numerous and important, but the list is too long to detail. The importation of raw cotton from India is, as I have said, disappointing, notwithstanding our great requirements, but there are signs of better things if a longer staple can be produced, and I believe this is possible to some extent. I hope the Government of India will continue their laudable efforts at improvement, for it would be a great thing for India if Lancashire was a free buyer.

Cotton is shipped, however, in large quantities to Continental countries, which also take freely of oilseeds, hides and skins, jute (raw and manufactured), and rice; and tea goes in some quantity to Russia through the Black Sea ports and by other routes. The war has cut off a great deal of this trade, and India is suffering to some extent accordingly, but to this I shall refer later on.

The next point of interest in connection with India's external trade is the question of transportation, and the extension of railways in India has always been a matter of the very greatest importance. The increase of the mileage has not kept pace with the times, and in recent years on several occasions the external and internal trades have been seriously hampered by the inability of the railways to handle the traffic expeditiously. The railway policy of the Government of India in the past was constantly assailed by the various railway administrations and by the commercial community as represented by the Chambers of Commerce. The complaint was that, instead of keeping ahead of the traffic and making preparations well in advance for a constantly increasing trade, the policy was one of over-caution, with the result that in recent years traders have often lost heavily by the delay in transportation, and at one time many orders had to be declined from overseas markets, and were, therefore, lost to the country for ever as merchants were unable to calculate on speedy delivery from the districts to the ports. I have told you already that in 1857 there were only about 270 miles of railways in India. Ten years later this had, however, increased to nearly 4,000 miles, and gradually, but very slowly, the figure has advanced to 35,156 miles at the present day, which, considering the extent of the overseas trade and the great possibilities of the future, is a small mileage for such a large country with a population of 315 millions. There are difficulties no doubt, in connection with the question of rapid expansion, and even if the present position was very much better than it is, it will always be a difficult problem after a good monsoon to move with rapidity the heavy crops harvested within a few months, which must, to a great extent, be handled and exported before the next monsoon sets in. To deal expeditiously with a vast trade under such conditions needs perfect organisation, about which complaints have not been serious, a sufficient supply of waggons, ample facilities for rapid transit, and plenty of storage space at the stations up-country and at the ports. It is largely due to failure in these latter respects that so many difficulties have been caused in recent years, but, owing to a free expenditure during the last two years, many of the defects and deficiencies complained of have been remedied, although, perhaps, to some extent, at the cost of a steady

increase in the mileage, which is still far below what it should be. The question of finding money for much more rapid extension and for equipment has been constantly urged as the true remedy for the unsatisfactory state of affairs which existed up to a year or two ago, and whilst I admit that there are difficulties to be overcome in this connection, I do not think the question, if viewed from a really practical point of view and judged by the necessities of the case, is an insuperable one, for I feel sure that if the possibilities of Indian trade were only realised, there would, in normal times be a far greater demand for investment in Indian railways, which are first-class securities. I have already said that matters have improved in the last two years, not, however, as regards extensions which are most important, but in general equipment, and I am only too pleased to be able to acknowledge the great efforts that have lately been made by the Government of India in this respect. For this financial year, notwithstanding the somewhat difficult circumstances in which the Government of India are placed owing to the war, a generous grant of £8,000,000 has been made against a revised budget estimate for the last official year of the large sum of a little over 11½ millions, and I gather from this that the Secretary of State, the Viceroy, and Sir William Meyer, the Finance Member, recognise the great importance of full expenditure on one of the most valuable assets of the Government of India. A policy of a rapid extension of mileage is, however, absolutely necessary for India's expanding trade, and I am one of those who believe that Indian trade is bound to increase much more rapidly in the future than it has done in the past. The people in India who have the control of the trade are full of energy and enterprise, and when this is the case there is no limit in such a vast and prolific country to rapid expansion. There will be, of course, an occasional set-back in the trade and traffic due to an insufficient or irregular rainfall, but this, after all, is a temporary matter which need not be taken too seriously into account in connection with the general railway policy of the Government of India. On this question I hardly need say more, as its great importance is now, I think, fully realised, and it is all for the good of India, her people and her revenues, that railways should be rapidly extended in many new districts, which would soon supply ample traffic of various kinds.

In recent years many feeder railways connecting with the main lines have been built with rupee capital raised in India, and the terms now offered by these companies, with the sanction of the Secretary of State, are much more satisfactory than they were a few years ago. These lines, generally speaking, are built to bring additional traffic to the main trunk lines, and the general results of these "feeders" have, so far, been very satisfactory; to such an extent that when any new line comes on the market the capital is nearly always subscribed with ease, for there is an immense amount of money in India awaiting good investment, and, so far as can be judged from the past, the returns from these lines steadily increase year by year. There is a great opening outside of India for investment, not only in these small "feeders" but in Indian railways generally, and I am glad to be able to say, with some confidence, that expectations of a satisfactory yield will rarely be disappointed. If, however, the main lines were given extended powers in the direction of "feeders," it would undoubtedly help matters, and this is a point which ought again to be considered. The people of India take a keen interest in their railways, and although some of their proposals in connection with the railway policy of the Government of India are somewhat revolutionary —as is instanced by a resolution brought forward in the Imperial Council at Delhi only a few weeks ago by an old Indian friend of mine—it is very satisfactory to feel that the importance of a successful railway policy is recognised as beneficial to the country in many ways, and that the all-important question of more rapid extension is likely to be kept well to the front in future years.

The prosperity of India, the welfare of its people, and the success of those who trade, is so wrapped up in the general question of railway administration and development, that I feel I may be excused a special paragraph on this most important subject, which the commercial community keep very much to the front—as they are bound to do if the foreign trade of the country is to be carried on successfully. Closely allied, however, with this important question is the extension of dock and harbour development, and in this respect, I am glad to say, the country has not lagged behind. There have been difficulties in the past in quite recent years, but the development of the ports is a matter which is always before the merchants of India, and great efforts have lately been made to bring dock facilities up to, and beyond, the requirements of the foreign trade, and,

generally speaking, with success. The growth of irrigation works in India is another matter of very great importance, and much good work has been done in this direction in recent years. The subject is one on which a great deal might be said, as a system of artificial application of water to the land for purposes of agriculture has existed in India—as in most other Eastern countries—from time immemorial; but it will suffice if I say that vast tracts, many millions of acres, largely in Sind and the South-Western Punjab, have been brought under cultivation by canals and tanks, and that valuable crops are being reaped therefrom. The advantage of irrigation will be recognised when I say that there are large tracts in the north and west which are almost rainless, and others, such as the Deccan, where cultivation is extremely precarious, owing to the great irregularity of the rainfall and the long intervals during which crops may be exposed to the fierce heat of the sun and to dry and scorching winds. The extension of irrigation in various parts of India is, therefore, a matter of great importance, not only to the people of India when famine threatens, but to the foreign trade, as large crops can now be raised on irrigated areas which otherwise would not be grown at all. Karachi, the great port of Sind, has benefited immensely in recent years by irrigation works in the northern part of the province and in the Punjab, and the great increase in the exports of wheat is mainly due to this cause. There is still, however, much to be done in this direction in other parts of India, and I was glad to see, only about a month ago, that another large scheme has been sanctioned in the Belgaum district of the Bombay Deccan.

Before I close this part of my paper, some figures of the average wages paid in various selected industries will be of interest. In cotton spinning and weaving mills the average paid is 23*s.* per month, not per week; in jute, 5*s.* 2*d.* per week, or about 22*s.* 3*d.* per month; and in coal-mining a little over 6*d.* per day, which seems a very small amount when compared with the wages earned by miners in this country. Agricultural wages generally are small, but they vary with the seasons, and when crops are bountiful they are high, relatively speaking—for labour in India is none too plentiful, as is generally supposed. The tendency of wages in recent years has been decidedly upwards, owing to a variety of causes, one being the generally increased cost of living due to the rise in prices, which, in some small measure has, perhaps, been brought about by the fact that, as the people are richer they are now supposed to be eating three meals a day instead of two. I hope they are, for if this is a sign of an increase of wealth they will be able better to stand a time of scarcity when it comes, and that it will come is certain, for the Indian monsoons vary considerably, and although for some years past they have been very good and crops have been bountiful, the time will come when they will be scanty and when there will be many areas of scarcity.

I will now refer for a few moments to the effects of this great and terrible war on the foreign trade of India, which, so far at any rate as exports are concerned, is carried on, as I have already mentioned, very largely with the Continent. When war was declared, the effect was immediate and far-reaching, not only on the foreign trade of India, but on the trade of the whole world, and for some little time business everywhere was very much disorganised. The uncertainty was so great that, for a time, all ordinary business was more or less at a standstill, and when foreign trade was resumed merchants in all countries had to adjust their calculations to absolutely changed conditions, to very much higher rates of freight, and, in nearly all cases, to a greatly depreciated exchange. The cost of production was also immediately affected and is still rising, and in many instances consuming markets were unable to adjust themselves rapidly to the altered conditions. The trade of India suffered with the rest, excepting in this one and very important particular, that, thanks to the prompt appreciation of the fact and to the support afforded by the Government of India, the gold exchange hardly varied, and India in her financial transactions has kept faith with the whole world. It is true, of course, that the ordinary financial transactions of the Government of India were considerably upset, and that, instead of sending money to this country to meet current liabilities, reverse remittances had to be made to the extent of nearly 9 millions sterling to maintain exchange; but the financial position was so strong and so sound that these reverse transactions were effected without any special difficulty, and when the Finance Member presented his Budget Statement to the Imperial Legislative Council early in March, he was able to announce that, notwithstanding a deficit for the official year just then ending, and the prospect of a further deficit for the present year, and notwithstanding also the falling off in trade and the expenses

to which the Government of India were being put in connection with the war, there was no necessity to impose additional taxation, and this statement, which was unexpected, was, naturally, well received. The inherent strength of India's financial position in a time of very great stress is a most satisfactory feature of Indian administration, and when the position is more completely realised and understood by investors in this and other countries, it should lead to a much larger investment of sterling capital in the country in railways and industrial enterprises of all kinds. India, at the present time, is making great strides in various ways, and many of its new enterprises, notably the Tata Iron and Steel Works, which is now making good progress, and the great hydro-electric scheme lately opened by Lord Willingdon to supply electrical power to the mills in Bombay —which will do away with the smoke nuisance and make Bombay a more beautiful city than ever—are due, I am glad to say, to the foresight and energy of enterprising men in Bombay, a city with which I have been associated, or, more correctly, in which I have lived for nearly thirty years. I feel, however, that, from the industrial point of view, India is only at the beginning of its expansion, and the country is fortunate in having, as an executive member of the Government of India, a representative for Commerce and Industry, for the advice and assistance of Government are often of great value in the development of new schemes. The Department of Commerce and Industry was founded by Lord Curzon when he was Viceroy of India, and it has been my privilege to have been intimately acquainted with the gentlemen who have held this important office. Might I in this connection suggest for favourable consideration that a Commercial Member of recent Indian experience might also be of value on the Secretary of State's Council in London? India, as I have said, will always be mainly an agricultural country, but there will always be an immense field for the profitable investment of capital in other ways, which, if wisely handled, will yield a satisfactory return. I do not mean that all Indian enterprises will necessarily be successful, but with good, honest management, a sound industrial undertaking is almost certain to yield a good return, and in railway extensions and development there are also great possibilities — some of the "feeder" lines to which I have already referred being at the present time, after only a few years' working, a very satisfactory investment for those who have been interested in them from the start.

Very fortunately for India the war commenced in what is known as the "off season," or during the height of the south-west monsoon, when the export trade is always more or less at a standstill, and when, as a rule, there is but little doing in imports. Had it begun a few months earlier the very greatest inconvenience would have been caused, for in the first six months of the year the foreign trade is at its height, the railways are working at full pressure bringing produce down to the coast, docks are full to overflowing, and the whole country is straining to market the valuable crops grown during the cold-weather months. When the war began, therefore, the Indian shipping season was, most fortunately, over; but even so, there were many steamers afloat for Europe carrying produce from Calcutta, Bombay, and other Indian ports, and as some of these boats were vessels belonging to German and Austrian lines they were captured by our fleet either before they reached Aden, or as they came out of the Canal, or whilst they were in the Mediterranean or the Channel. The steamers of the German Hansa Line have carried for years large quantities of Indian produce to German and Belgian ports, and numerous vessels of the Austrian Lloyd Company were engaged in the trade between India, Italy, Austria, and other places in the Mediterranean, Egypt, and elsewhere. All boats *en route* belonging to these two lines had either to take shelter in a neutral port or were captured, the latter with their cargoes, which belonged, to a great extent, to British and neutral merchants by whom they had been shipped in the ordinary course of business before the war broke out. The capture of these cargoes has led in many cases to complications, and at the moment it looks as if shippers may be involved in heavy losses through no fault of their own, but I am glad to note that, although the Prize Court decisions in many of these cases may be adverse, and, consequently, a great hardship to many British merchants, our Government have appointed a special committee, to which, I understand, appeals can be made for compensation; and, under the circumstances, I can only hope that a liberal and generous view of the position will be taken by the members of this committee, so that, in addition to the ordinary — or, should I not say, the extraordinary — trade losses of the present time, British and neutral merchants may not be called upon to bear other losses which they

were unable to protect themselves from in any way.

The effects of the war on the foreign trade of India were, as I have said, immediate; and in August and September the imports into, and the exports of merchandise from, India fell off very materially when compared with the same two months in the previous year, which, however, as regards imports, were, perhaps, above the normal. The export trade in these two months suffered most. The falling off was just over 50 per cent. as compared with the previous year, the chief reasons being the complete stoppage of business with Germany and Austria —both valuable customers—and the unwillingness of merchants to ship to neutral countries on the Continent, owing, in some measure, to difficulties of finance. Steamer freights also rose rapidly, and as tonnage was scarce owing to the heavy requirements of Government for trooping and other purposes, there were not the usual opportunities of dispatch. Everybody, in fact, waited to see what was going to happen, and, as a consequence, a great number of running contracts were either delayed or cancelled. At some of the large ports a rather serious view was taken of the position by a section of the community - chiefly the Marwaree or trading class, whose homes are in the districts—and they departed carrying with them as much gold as they could lay their hands on. Because of this, and owing to certain wise restrictions of Government, gold in circulation became scarce and went to a premium. There was also a considerable run on the Savings Banks, and Government Notes were presented freely for encashment both demands being, however, promptly met. Then the "Emden" appeared, and whilst she was in and near the Bay of Bengal, shipping from Calcutta and the east coast was more or less at a standstill. The bombardment of Madras aggravated the position, and as wild rumours spread rapidly over India, an immediate revival of trade seemed at that time to be quite out of the question. The sinking of the "Emden," however, changed the position entirely, and many traders who were, no doubt, tired of sitting up country doing nothing, seem then to have concluded that, at any rate, so far as they were concerned, the war was probably over, and by degrees they began again to take an interest in business. In nearly all the accustomed channels trade was very much checked, and in this connection I cannot do better than quote from Sir William Meyer's extremely interesting Budget speech, which many of you will, no doubt, have read. In referring to difficulties in Calcutta in connection with the jute trade, Sir William pointed out as a sign of the times that, whereas between August and October 1913 the issue of rupees from the Calcutta Currency Office in connection with the financing of the jute crop amounted to some 13 crores of rupees, the net issue in the corresponding period of 1914 was only about 56 lakhs, which is just over half a crore. As regards tea Sir William Meyer pointed out that, after the United Kingdom, India's largest customer for this commodity is Russia, and the disturbance to finance which accompanied the war rendered it impossible, at first, for Russian buyers to make their usual purchases. The difficulty was, however, subsequently surmounted, in part by financial arrangements made between His Majesty's Government and that of Russia, which supplied funds in London towards exchange facilities for Russo-British trade. In this and other ways trade gradually revived, and, as so often happens in exceptional circumstances, new markets also began to appear, to such an extent that before very long there was an active demand for jute, tea, coal, and many other articles. Russian orders for shipment to Vladivostock were also in the market, and, as I have said, from many other quarters a new demand seemed to spring up. The effects of this on the export trade were not apparent until November, but even then and in December the falling off was heavy in comparison with the previous year. It is, however, very satisfactory to note that, after a severe check, trade in many directions is reviving rapidly, and I will illustrate the present position in the East by referring to the remarks of the chairman of one of the Indian Exchange Banks at the annual meeting a few weeks ago, when he said that:—

"The rice crop in Burma is good, the wheat crop in India is excellent, the tea industry in India and Ceylon is most prosperous, the jute mills in Bengal are likely to show good results in the present year, and the rubber industry is in quite a healthy condition."

Rubber is not really an Indian crop, but tea and jute are produced very largely, and as the wheat acreage this year is very large, and the crop, owing to favourable weather, an exceptionally good one (the latest estimate I have seen is a production of over 10¼ million tons on an area of just over 32 million acres, against an estimated out-turn last year of 8½ million tons), there is, or should be, a large amount—perhaps 2 million tons available for export. Only a

small proportion of the Indian wheat crop is, however, exported in normal times; but whatever the amount, it has an important influence on the world's markets, and, consequently, on prices. The export of wheat for the present, owing to the war, is being controlled by the Government of India, and conditions, to some extent, are, therefore, artificial; but it is a comfort to know that, after a year of rather poor supply, India has now gathered a splendid harvest, and that, after fully supplying her own needs, there will be a large amount available for us and our Allies. Calcutta has benefited most by the revival of trade—coal, jute, and tea being very important items in Bengal. Coal has been in great demand owing to the scarcity of tonnage which is due to so many vessels having been taken up for war purposes, and freights, owing to this and increased working expenses, have consequently risen. Jute has been bought freely for a great variety of purposes and tea has been in active demand for our Navy, for the troops in the field, and for general consumption. The improvement in Calcutta trade has added very largely to the receipts of the railways serving that port, and in comparison with the previous year's figures the result is now generally satisfactory. Not so, however, in Bombay and the western ports, for the receipts on the large trunk lines serving these districts fell off very heavily at the commencement of the war, and are still very far below the corresponding figures of last year. The foreign trade of Bombay has not had the same stimulus as Calcutta, owing to the different articles dealt in, cotton and oilseeds being the largest commodities handled in Bombay, and there cannot be much increase in the exports of cotton and oilseeds to Europe until the war is over. Japan, it is true, has been a good buyer, but the trade lost by the shutting off of Germany and Austria cannot well be replaced. As regards the import trade, there was, of course, a serious check all round; but after a few months business began to revive again, and India for some time past has been a valuable market to our manufacturers. Looking back a few months, it is wonderful how the Indian trade in merchandise has revived, and how rapidly India has adjusted itself to new conditions, and, in many cases, to much higher prices. Although freights in many directions have doubled, and, in some cases, trebled, trade still goes on, and is not likely to be checked if India has another good monsoon. The abnormal conditions have, no doubt, been profitable in some directions, but trade has been worked under many difficulties and with many additional but unavoidable risks. There is no reason, at the present time, to take a pessimistic view of India's foreign trade. Some valuable markets have been temporarily lost, but others have been found, and if the export trade can be carried on, the trade in imports will also continue. A demand since the war began has sprung up in this country for many articles which, in the past, have been bought in Germany; and efforts, I am glad to say, are being made to capture this trade, which is of considerable value. The question has been taken up with vigour by His Majesty's Government, and a very interesting collection of articles is now on exhibit at the Commercial Intelligence Branch of the Board of Trade at 32, Cheapside. I have been there and would recommend anyone interested in trade matters to visit these offices and to see for himself the many odd and end articles for this, generally speaking, is a fair description of them - which have been made in Germany and in Austria for sale in India, and the trade I know from experience has grown very rapidly in recent years. I am told that many of our merchants and manufacturers have inspected these exhibits, and that much good, from a trade point of view, is likely to result from this praiseworthy effort of our Government. I am not one of those who run down and belittle the British manufacturer, as he is a man of great energy and resource, but he does not always pry into little things in the same way as the Germans have done, nor does he care very often to make the small and cheap articles which, in many directions, Germany has made a speciality; but I feel confident that, as a result of the Board of Trade's efforts in this direction, the best of this German trade will be secured by our manufacturers, and this will be a valuable addition to our trade with India. I do not want to go into the past, but there can be no doubt that the passing of the Merchandise Marks Act in India a good many years ago, which compelled all foreign goods to have the country of origin stamped or marked upon them, has been the finest advertisement possible for German goods in the Indian markets, and a great deal of good business has been lost on this account to British merchants. As regards the exhibits to which I am referring, expensive and elaborate machinery will, in some cases, be necessary to produce them, but if there are fair prospects of the trade remaining in this country our manufacturers are not likely to be backward; and many of them, I am told, are astonished at

the variety and ingenuity of the articles produced in the manufacturing districts of Germany. In India, as incomes are small, there is an enormous demand for cheap supplies, and as the goods from the Continent are, in nearly all cases, very nicely got up, the business has rapidly increased, and this is a point our manufacturers must bear in mind if they are to capture the miscellaneous trade which for many years past has been done by Germany and other Continental countries. A perusal of the Board of Trade's list of articles for which they have had inquiries is extremely interesting, and I can only hope that this great help to commerce will become a permanent part of the work of our Board of Trade, and that it will lead to the revival of many industries in this country, and to the creation of many new branches of business. I am glad to have this opportunity of testifying to the good work that is being done to develop our trade, which, I am sure, in time will prove to be very valuable.

And now, before I close, I would refer for a few moments to another subject which does not directly affect our trade, but is of the greatest importance to the future of our great Indian Empire, and would say a few words in appreciation of the splendid efforts India has made and is still making on behalf of the Empire in the war we are now waging on the Continent and in many other parts of the world. I remember what India did at the time of the Boer War. I was in Bombay when her brave troops left, and to one who has lived in India so long, and has liked and appreciated the people, it is splendid to know that they have come forward as they have done, princes, chiefs and people alike, spontaneously and enthusiastically, and have vied with each other in offering men, money and equipment for the successful prosecution of our cause. The clash of arms appeals to the Rajput chieftains and to the people of Northern India, and it is, I know, a privilege and an honour to them to be allowed to serve their Emperor on the field of battle. The magnificent response made by our Indian Empire has evoked the greatest enthusiasm in this country, and has caused, I believe, and I am glad to think, the greatest surprise in the countries with whom we are at war. It is a splendid testimony to our successful rule which, now that the world has risen in arms to decide whether in future government is to exist for the benefit of the people, or the people for the benefit and ambitions of government, is appreciated as it has never been appreciated before. There could be no doubt whatever as to the answer India would give, and she has given it already in the splendid response she has made to our call for the maintenance of free and enlightened government. By our wise and liberal treatment of the Indian people we have proved to them the sincerity and justice of our rule. We have given them the fullest possible scope compatible with good government, we have enlarged the Legislative Councils—a wise and prudent measure initiated and carried out by the late Lord Minto and by Lord Morley. We have admitted their ablest men also to the Executive Councils as well as to the Council of the Secretary of State, and there will always, I am sure, be clever, sound and patriotic men, willing and anxious to fill these posts, for in this way they can serve their country and their fellow men. And one of the best of these has lately passed away in the person of the Honourable Mr Gokhale—an enthusiastic and patriotic Indian, who died, most unfortunately, only a few weeks ago. He was a man for whom I had always a great liking and a great respect, and his influence was always for good. All honour, then, to the brave men who are fighting for us in the trenches in France and in Flanders, in the Persian Gulf, in East Africa and elsewhere, and all honour to those who have laid down their lives for the Empire. Their memories will not be forgotten, and their heroic deaths will help to draw us closer to our Indian Empire, and our Indian Empire closer to us.

DISCUSSION.

THE CHAIRMAN (the Marquess of Crewe), in opening the discussion, said he felt certain that the concluding passages of the paper would have struck a note of sympathy in the mind of every member of the audience. It was impossible to reiterate too often in this country our sense of the debt which we owed to the people of India, without distinction of race, or class, or of religion, for the part which they were taking in the present stupendous struggle almost all over the world. He had had more than one opportunity, and he should have more, of expressing, as Secretary of State for India, his own sense of the debt which was owed in the first place to the Indian troops, who, in the different scenes of combat, had equalled and, if it were possible, had excelled the feats of the wars of the past, then to the Indian princes, who had carried on the traditions both of chivalry and of munificence which they had inherited from long lines of ancestors; and lastly, but not least, to the whole people of India, men and women alike, who had come forward according to their different opportunities and means to testify their support to

the Government of the King-Emperor, and had done so because they knew that our cause was that of righteousness and justice. He did not propose to make any attempt to follow the author of the paper through the comprehensive and most interesting review which he had given of the commercial and industrial activities of India. All he (the Chairman) would attempt to do would be to call attention to one or two points relevant to the later part of the paper, namely, the particular condition of affairs which had been brought about in connection with Indian trade and industry by the war. In the first place, he thought it would be altogether idle to disguise the fact that we could not expect, and indeed ought not to expect, the ordinary small trader or cultivator in India—whose affairs at ordinary times depended in their vicissitudes only upon the caprice of the season or of the market—to regard with complete indifference or acquiescence every result which might be brought home to them personally through the present gigantic convulsion. It was, therefore, the serious duty of Government to attempt, as far as possible, to temper to those people such results, and that was the origin and the cause of a transaction which Sir Charles had mentioned, namely, the veto which had been placed upon the export of wheat on private account until well into the spring of next year, and the substitution of sale on Government account. That also had been the object and purpose of the measures to which Sir Charles alluded which were taken by Government for the purpose of supporting exchange; and he was grateful to Sir Charles for the approval with which he had spoken of those measures. There were only two matters to which he further wished to refer- two desires which he entertained in connection with the present crisis. Both of them were connected with subjects to which Sir Charles had alluded. In the first place, it was his earnest hope, and he was certain it was also the hope of the Government of India, that it might be possible throughout the present struggle—of which the end could not be seen—to continue the policy, which had so far been pursued, of not imposing any fresh taxation upon the people of India. In this country it had been found necessary—and, he believed, altogether wise to follow a diametrically opposite road. But the people of India were giving exceedingly large amounts of money towards the prosecution of the war, and what was infinitely more precious than money—they were giving many lives. That generosity was true of both countries, but what was special to India, and which was at the bottom of the desire not to impose any further taxation on India, was that, as was well known, it was exceedingly difficult, in the circumstances of India, to devise any scheme of raising fresh revenue by taxation which did not hit the very poor classes in the country. If it were merely a question of taxing the superfluities of the wealthy, the problem undoubtedly would assume a somewhat different aspect. His other desire was based on the hope that, to as small an extent as possible it might be found necessary to curtail expenditure on productive works in India—such works as railways, canals, and the like. On that subject Sir Charles had dwelt at length. Sir Charles had stated what the great railway system of India had done for the country and how warmly he desired that it might be extended. The same considerations applied to irrigation, to harbour works, and to many other public enterprises; and, so far as was possible, everything had been done not to lower the scale of expenditure on those public objects to a greater extent than the circumstances made absolutely necessary. But it was necessary in that connection to look at the conditions here. Probably all were aware that it had been found necessary in London to limit public issues of capital of all kinds, whether they were connected with municipal enterprise or with private enterprise, even although they might apply in a great number of cases to objects of the first importance, which everybody wished to see promoted and carried through. That embargo on the issue of capital applied not only to this country but also to the self-governing dominions and the colonies, and it applied also to India. India issues on the London market were most rigidly, and of necessity, limited Bearing in mind what Sir Charles had stated as to the hopeful advance which had taken place of recent years in India in the investment of Indian capital in that country, he (the Chairman) desired to point out that anybody in India possessed of capital to invest and who would take a share, be it large or small, in a rupee loan issued by Government, was not merely doing something which assisted in the development of the country but was thereby positively assisting in the prosecution and carrying on of the war. The limitations which had to be imposed on the issue of capital either for India or for other parts of the Empire in our market here were founded on the fact that the maintenance of British credit stood only second in its effect on the prosecution of the war if it be second to anything—to the continual supply of men to go to the front, and the supply of munitions with which to arm them. He said, therefore, that the investor who in India would, according to his means, come to the front in that way was doing a public service. All recognised of course, the almost unending liberality which had subscribed in India to the various war funds which had been raised. Nothing too grateful could be said of that, but there should also be kept a word of distinct praise for the Indian patriotic investor.

Mr. C. C. McLeod said on an occasion like the present, one was expected to criticise the paper that had been read, but he was bound to say that in all he had heard in the very interesting address which Sir Charles Armstrong had just given he could not bring himself to criticise anything. On the contrary, he was very much in accord with all the author had said in regard to the subject. Sir Charles had covered a great deal of ground, starting

with the early history of India and its trade, and following it up by giving the result of monsoon effects, together with a very great deal of instructive knowledge in regard to the growing and cultivation of cotton, wheat and other articles—not to speak of statistics of a very comprehensive nature. He had also mentioned the jute trade, and spoke of the eastern side of India, which more closely affected Calcutta than Bombay. The jute trade certainly was a most important one, and a monopoly of Bengal. It was, however, at the disposal of every country in the world, without any prohibition or protective disabilities. As a contrast to the facilities given to the Germans for getting jute (for which there is no substitute in the world) he (the speaker) would point out the methods of the Germans in the only colony in which they were producing sisal fibre, viz., German East Africa. There every machine was of German manufacture (Krupp's), shipped in German bottoms, to German ports only, financed through German banks, and sold through German brokers, and all disputes arising were to be settled by Germans only! Fortunately the tentacles of that octopus had now been clipped, and he trusted it would not be long before the body of the beast was as extinct as the Dodo. The growth of the jute industry had been a remarkable one, and the uses to which the fibre were now put were varied and extensive, and the manufacture of it into cloth and yarns in Calcutta was a very large trade in itself. Instead of the two or three mills in Calcutta which existed when he went out in 1878, there were now about fifty mills, exporting about a million tons of goods manufactured from jute to every corner of the world. Those mills employed a very large number of natives, who got well paid and were well looked after. The tea industry was also one that had expanded very largely in late years, and had reached a very considerable figure of over 250,000,000 lbs. of tea from Northern India. Another important industry which had succumbed to the competition of German chemistry was indigo, and he hoped and trusted that it would now have a chance of being resuscitated on a permanent basis, and that the German Badische would never be heard of again. Sir Charles had alluded at some length to the importance of the railway system in India, and he (the speaker) hoped with him that its great importance was now fully realised. It was a subject he himself had had the privilege of bringing before the noble Chairman on more than one occasion, and all appreciated his lordship's practical sympathy in doing all he could to further its extension in India. He might, in connection with that subject, refer to what was known as the Mackay Committee in 1908. Several witnesses before that Committee gave their opinion that the 30,000 miles then open would be in the near future increased to 100,000 miles, and the Committee, from the evidence before them, stated: "We believe that even their estimate of mileage is short of what will ultimately be found necessary in India, and we are convinced that there will be fruitful fields for large reproductive expenditure on railways in the country for years to come." He might also add that Sir Guy Fleetwood Wilson, in his Budget speech of 1913, remarked, "We have in our railways a splendid asset," and acknowledged "the immense significance of the railways as an instrument of general progress; their necessity for development of trade; their growing, and, indeed, their momentous importance to the finance of India." He further added: "Our responsibility is all the greater now that they have attained a position of supreme importance in our financial system." The introduction of feeder lines to the main railways was of immense advantage, and promised to become a very extensive proposition. The Secretary of State, in sanctioning a positive 3½ per cent. Government guarantee to approved feeder lines, had made a marked advance, not only in that many more lines were now in course of construction, but what was perhaps of the greatest importance, the capital for these lines was being subscribed entirely in India. The natives had come forward as free subscribers, and it might interest the meeting to know that very lately two railway projects were put before the Calcutta public, when £700,000 was subscribed in a few days, many of the subscribers being rajas and landholders, in sums of £20,000 to £50,000 each. The effect on the old system of hoarding was obvious. Akin to the railway system of India came the question of port facilities. There was no advantage in extending and equipping railways if the ports to which they centred were not capable of dealing with the goods they brought forward for export. Great advance had taken place in that direction. Sir Charles would remember when Karachi was only a sandbank and Bombay a very small port indeed, while in Calcutta, when he (the speaker) went out there in 1878, there were only a few jetties alongside the River Hooghli. To-day, Karachi was a very large port, Bombay had converted her harbour into extensive docks, and Calcutta had not only extended her jetties, but had made extensive docks which were now to be doubled. He doubted very much if even all that could cope with the increased traffic, and he would like to read a short paragraph of what he had said at the annual meeting of the Bengal Chamber of Commerce in 1913 "But it appears to me that a very bold programme will be necessary for Calcutta if we are to pay any attention to what the increase of the past few years has taught us. The imports between 1910-12 for all India have risen from 60½ millions to 85 millions, while in the same period exports have advanced from 80½ millions to within a fraction of 100 millions; these are the figures for all India. Now, we confine ourselves to Calcutta and take the advance during the last three or four years at a safe percentage, it has been put as high as 12, official figures bring it out to something like 9 per cent., which corresponds with the increase on inland trade into Calcutta; but taking into account

the higher value of most of the commodities, it will be sufficient if I take it at 6 per cent. and multiply it by sixteen years, you will have at the end of that time double the export business you have now, and no doubt a very considerable increase in imports as well, and surely a very bold programme in the face of such figures would be whittled down to one of ordinary common prudence." It must never be forgotten that India is not only a country, but really a continent, and that, with all those increased facilities, trade was bound to increase by leaps and bounds. He was one of those who, like Sir Charles, was full of optimism where India was concerned, and shared with him the feeling that the industries were only in their infancy. As most knew, the agricultural industry was a very extensive one, but, withal, a very crude one. Taking the instance of the ordinary cultivation where the ground was tilled with the aid of a piece of wood pulled by a pair of emaciated bullocks, and the seed sown perhaps out of stock which had never been changed since it was handed down from the Ark, it did not require a great stretch of imagination to see that, if the form of cultivation were improved and fresh seed imported, the result would be a hundredfold yield. Like all places in India, the trade in Calcutta had been thoroughly upset and paralysed for a time by the war. Exports had ceased owing to the difficulty in negotiating drafts. But, thanks to the prompt action of the Government and the stability of the currency system, these difficulties were soon overcome, and trade was in full swing early in September. Contrary to expectations, the markets for jute and tea remained steady, and, in the case of the latter commodity, advanced latterly to prices not seen for the past twenty-five years. The only fear in the future was the difficulty in securing freight to bring home the large crops that are expected this season, but possibly it would not be so bad as expected. Sir Charles had referred to the help that we had received from our Indian fellow-subjects in the wonderful effort they had made in showing their loyalty to the British Crown. It was most gratifying. He was glad to think that, as a member of the Committee of the Indian Soldiers' Fund under the able chairmanship of Sir John Hewitt, they had been able to add by voluntary subscription to the comfort of the troops who had come over to fight for us, and he hoped to go over to France very shortly to consult with Sir James Willcocks—their gallant commander—in regard to what comforts they might require during the coming hot weather. He would conclude by reading an extract from a recent letter from Sir James, which he thought would be considered gratifying. Sir James said: "It is good of you looking after the welfare of my men. They are the most loyal fellows that ever lived, possessed of that extraordinary nature which will endure the greatest trials and fight bravely for the Government they serve. This India experiment in Europe will live in history as the most remarkable example of the reality of British rule."

Sir Alexander McRobert said he desired to point out that the Bombay man and the Calcutta man always took rather a narrow view of India. They knew all about exports and imports, but forgot that there were many other things to consider when dealing with the trade of India, especially with regard to the war. The last speaker had mentioned indigo. Indigo used to be an important article of production in India, but the introduction of the synthetic method of manufacture reduced the price to such an extent that the planters thought they could not live, and dropped the cultivation. Accustomed as they had been to prices ranging from 4*s.* to 8*s.* per lb. year after year, they had never felt the necessity of looking for higher yielding varieties of the indigo plant, nor of taking steps to improve the methods of cultivation and manufacture. The margin of profit was so great that fortunes were made easily and quickly, and the Macleods, the Mackinnons, and the Mackenzies—they nearly all came from the west country—were able to retire to their native land, after a few years of existence as a sort of feudal barons, and buy islands in the Hebrides. Then when the price fell to 2*s.* per lb., under the stress of the competition of synthetic indigo, they gave up the fight without a real struggle—which was simply playing into the hands of the Germans. He was one of those who had always maintained it had been a mistake to give up the cultivation of indigo. He was credibly informed that fine Behar indigo could be produced at about 1*s.* 8*d.* per lb., by taking advantage of the results of recent research regarding the best methods of cultivation and manufacture, and working on strictly economical lines—in short, by taking a leaf out of the book of the Java planter. That was cheaper than synthetic indigo at 8*d.* per lb. for 20 per cent. paste; and now the German product was out of the market, fine Behar indigo was selling at 14*s.* per lb. It was, therefore, reasonable to expect that one effect of the war would be the resuscitation of the indigo industry in India. The area under indigo was certain to be largely increased if the seed difficulty could be overcome. With regard to the question of wheat, it was anticipated that India would be able to export during the present season, under Government auspices, something like 2,000,000 tons of wheat, on which £5,000,000 profit was expected to be made. He was glad to learn that that profit was not to be regarded as revenue, but was to be earmarked for the benefit of the ryot. The area under wheat in India might be taken as 32,000,000 acres, but the average outturn per acre was something less than 11 bushels. In this country the yield had been gradually worked up to 32 or 33 bushels. This high outturn was got by more intensive cultivation, by the free use of fertilisers, and by employing for seed only the best varieties of wheat, evolved by laborious cross-fertilisation and toilsome experiment. The difference was very great, and he would not be so extravagant as

to ask India to even double the outturn all at once. He would ask for only the modest increase of one bushel per acre, which should certainly be possible of attainment. At the experimental farm attached to the Agricultural College, Cawnpore, Mr. Martin Leake, by merely an extra and deeper ploughing at the right season, had got outturns of over 20 bushels per acre. The Howards, at Pusa, had produced a new wheat of high yielding qualities, and it had been sown over a considerable area in the Aligarh district. Efforts were being made to introduce these improvements over a gradually increasing area, and a marked effect might be looked for before long. A very little arithmetic would show that if the output was increased by only one bushel per acre, it meant, at the present price of wheat, £12,000,000. He was hoping that one result of the distribution of the £5,000,000 would be that the cultivator would be induced to cultivate his land better, to plough a little deeper, to use better seed, and to employ fertilisers. In the latter connection he would remind them that there was a very large export of bones from India, which, in his opinion, was little short of a crime. Every ounce of bone that could be collected should be applied to the soil—finely ground or dissolved—for the bone contained practically all the phosphoric acid removed from the land by the crops, and if it was not returned the soil became gradually impoverished. He would prohibit absolutely the export of bones from India

Earl Brassey, G.C.B., said it afforded him great pleasure to move a cordial and well-merited vote of thanks to the author for his most valuable paper. When he thought of his near relatives, Lord and Lady Willingdon, doing their best in the responsible position which they filled in Bombay, it was a great pleasure to pay due honour to one who had been chairman of the Chamber of Commerce of the magnificent port of Bombay.

Mr. T. J. Bennett, C.I.E., in seconding the vote of thanks, said in giving the paper Sir Charles had co-operated very willingly and very admirably with one of the chief purposes of the Indian Section of the Society. He might almost define that purpose as that of a beneficent trap for catching Anglo-Indians. It had been a declared purpose of the Indian Section for some years past to "rope in" Anglo-Indians of distinction as soon as they returned home. One possible reason for that was that it had been said, on authority which few would dispute, that when the Anglo-Indian had left India and settled at home he very soon forgot all about the country, that his knowledge of it evaporated, and that he ceased to be in a position to judge of what was going on in India. No such charge could be brought against Sir Charles Armstrong, who was an up-to-date authority upon all Indian matters.

The vote of thanks was put and carried unanimously.

Sir Steyning W. Edgerley, K.C.V.O., C.I.E., said the present meeting brought to a conclusion the work of the session of 1914-15. For the past twenty years it had been the custom for Secretaries of State to show their interest and their sympathy in what was done in the Indian Section of the Society by taking, on occasions, the chair at the meetings, but no Secretary of State had come there in circumstances of a year so responsible and so strenuous, and when the call on his time was so great. However, he (the speaker) had not thought it right to conclude the session without giving Lord Crewe an opportunity to be present, although he felt very great diffidence in making the suggeston. He had made it in a very tentative form so that it should be very easy for Lord Crewe to refuse, but the suggestion had been met with a readiness which was extremely cheering, and which seemed to show that there was some truth in the old adage that it was the busiest of men who had the most leisure. He desired on behalf of the Committee to state to Lord Crewe how very highly they appreciated his kindness in attending.

The Chairman, in reply, said in any case it would have been a distinct pleasure to him, as well as a duty, to follow the example of his predecessors at the India Office in presiding at one of the meetings of the Society. He had been more than repaid by having had the pleasure of listening to Sir Charles's illuminating address on a subject of perpetual moment and of thought to himself, and upon which he was very glad to have the benefit of Sir Charles's opinion

DOLL-MAKING IN STAFFORDSHIRE.

An article appeared in the *Times* in August last giving a summary of specific trades which were at that time solely carried on by the Germans. This included some remarks about the making of dolls and toys, and English people were reminded that this trade had at one time flourished exceedingly in England. This at once produced a desire to investigate the matter and, if possible, solve its difficulties. Inquiries showed that the art of doll-making in England had almost entirely been given up for some forty to fifty years, first one and then another manufacturer being driven out of the trade by the cheap German doll-maker, till at last every doll sold in England was imported entirely from Germany—heads, eyes, bodies, and in many cases clothing. Exactly the same state of affairs existed in Russia, Belgium, and France. The last country, however, still retained some of its factories, and is now in a position to supply a moderate number of French dolls.

The art in England had so entirely died out that all inquiries and advertisements failed to discover anyone who had even been trained in this industry, and therefore the only way was to take courage and rush in where possibly the angels would have feared to tread.

Ignorance on the one hand, and a desire to succeed on the other, led us on through months of many and apparently insuperable difficulties, and finally ended in the formation of the British Toy Company, with a small factory at 29, High Street, Stoke-on-Trent.

It would be as well to mention a few of the troubles which beset us. To begin with, glass eyes were not to be obtained in England, having all been made in Austria. This, however, has been partly overcome by the energy of a glass-eye (human) manufacturer, who came forward and produced what was wanted. Then came the question of the heads. This seemed at one time an almost impossible difficulty; however, some manufacturers in the Potteries made many and costly experiments, and now at last one or two have produced a head, which it is safe to say is quite as artistic, and quite as well finished as the German head. The material for stuffing the body presented a great difficulty; but after a great many experiments a material has been produced which gives satisfaction to all. At present the whole work is done by hand, but we have made exhaustive inquiries into the question of machinery, and that is merely now a question for the near future. No doubt the English doll has still many stages to go through before it reaches perfection, but the first corner has been turned and we now await the co-operation of the British public. It is orders we want, and without this stimulus we cannot hope to improve, nor can we arrive at our main object, namely to establish in this country a new and healthy trade, which will not only be the means of securing permanent employment and good wages for many, but be one of the many factors which shall once and for all obliterate those words—"Made in Germany."

All inquiries should be addressed to The Secretary, British Toy Company, 29, High Street, Stoke-on-Trent.

GLASS RESEARCH.

The Council of the Institute of Chemistry of Great Britain and Ireland have published a short report summarising the work of the Glass Research Committee, appointed in October last, to conduct investigations with a view to arriving at suitable formulas to be freely available to manufacturers willing to assist in maintaining the continued supply of laboratory glassware. The importance of this work to numerous industries, particularly those concerned with the production of war material, will be apparent.

The committee consisted of Professor Raphael Meldola (then President of the Institute), Mr. Bertram Blount, Mr. Otto Hehner, Professor Herbert Jackson, Mr. Walter C. Hancock, and Mr. T. R. Merton. At their first meeting Professor Herbert Jackson reported that, in conjunction with Mr. T. R. Merton, he had already commenced experiments at King's College, London, with a similar object in view, and that he and his collaborator were prepared to give the committee the results of their work up to that date, and to pursue investigations on lines to be determined from time to time by the committee.

Since then the research has been continued uninterruptedly, the chief aims being: (i.) to produce working formulas for all glasses used in laboratory work, and (ii.) to ascertain the influence of various ingredients on the physical and chemical properties of glasses. The work was extended to include glass for miners' lamp-glasses, at the suggestion of the Home Office; and also glass for ampoules, to meet the needs of wholesale pharmaceutical chemists engaged in the production of army medical requirements. The committee have also examined and reported on samples of British and French laboratory glassware, produced since the beginning of the war, a number of the specimens being made from formulas similar to, and in some cases almost identical with, those recommended by the committee.

The committee have had before them many specimens of glasses used for various purposes, of which analyses have been made by Mr. Blount, Mr. Hancock, and Mr. Hehner. It has been found, however, that mixtures prepared in accordance with the analytical results were not always satisfactory; but the analyses were helpful in suggesting synthetic experiments, and during recent investigations some intricate analyses made by Mr. Gilbert J. Alderton, under the supervision of Mr. Blount, have proved especially valuable. Apart from the analyses, the work has been almost entirely carried on at King's College by Professor Jackson and Mr. Merton, and by the former at his own house. The work has involved a careful study of the chemistry of silicates, aluminates, borates, etc., in their relation to the manufacture of glasses. A detailed report of these experiments will be published in due course.

Up to the present time the research committee have reported eleven formulas for glasses for various purposes, based on the results of about 400 experimental melts on a scale large enough for drawing rods and blowing small vessels. In addition, a very great number of experiments have been made in order to study the influence of the various constituents employed. No formula has been issued without submitting the specimens made to rigorous tests to prove their suitability for the purposes for which they are intended. Moreover, by varying the experimental working conditions, it can be said with reasonable confidence that the mixtures will prove equally satisfactory under the actual working conditions of a glass furnace. The question of workable temperatures has been carefully considered, and, so far as it is possible to judge, the melts on a small scale indicate that even better results will be obtained on the industrial scale. This view has been justified by the samples already received from manufacturers who have tried some of the formulas.

In deciding the formulas it has been found

necessary to pay special attention to the proportions of basic and acidic substances in respect of the action of glass mixtures on clay crucibles during fusion, and it has been shown by careful investigation that the formulas proposed give melts in which the influence of the ingredients of the crucibles is very slight, and in some cases practically inappreciable.

The following formulas have been communicated to a number of manufacturers who have expressed their interest in the progress of the investigation, and to scientific workers who are conducting similar experiments:—

Soft glasses, suitable for ordinary chemical laboratory ware:—

	Parts.
(1) Sand	67·0
Sodium carbonate (Na_2CO_3)	34·2
Calcium carbonate	11·6
Alumina (Al_2O_3)	6·5

A soft glass which does not give up alkali readily to water, works well in the blowpipe and does not devitrify readily.

	Parts.
(2) Sand	67·0
Sodium carbonate (Na_2CO_3)	29·0
Calcium carbonate	9·6
Calcium fluoride	1·6
Alumina (Al_2O_3)	8·3
Boric anhydride (B_2O_3)	2·0

A soft glass of higher quality. Does not give up alkali under severe tests. A kindly working glass before the blowpipe, and very difficult to devitrify.

A resistant glass suitable for pharmaceutical purposes, ampoules, etc.:

	Parts.
(3) Sand	67·0
Alumina (Al_2O_3)	10·0
Calcium carbonate	12·5
Magnesia	0·5
Potassium nitrate	1·0
Sodium carbonate (Na_2CO_3)	17·0
Boric anhydride (B_2O_3)	8·0

This glass is intermediate in hardness between soft glass and combustion tubing, is highly resistant to chemical action, withstands changes of temperature well, and should be a very suitable glass for high-class beakers, flasks, etc.

Glasses for combustion tubing:

	Parts.
(4) Sand	68·2
Alumina (Al_2O_3)	6·2
Barium carbonate	8·8
Calcium carbonate	13·0
Potassium nitrate	4.3
Sodium carbonate (Na_2CO_3)	5·5
Boric anhydride (B_2O_3)	5·5
Calcium fluoride	1·0

This glass resembles Jena combustion tubing very closely indeed. It has practically the same fusing point. It fuses on to Jena glass perfectly, and is indistinguishable from it before the blowpipe and in its behaviour on prolonged heating below its fusing point. The presence of the small quantity of calcium fluoride facilitates the incorporation of the ingredients. The sodium carbonate can ber educed to 1·34 parts, provided 7·93 parts of anhydrous borax be used in the place of boric anhydride.

	Parts.
(5) Sand	68·2
Alumina (Al_2O_3)	6·2
Barium carbonate	8·8
Calcium carbonate	14·2
Potassium nitrate	4·3
Sodium carbonate (Na_2CO_3)	5·5
Boric anhydride (B_2O_3)	5·5

This glass is practically of the same composition as No. (4). It is not so easy to make or to work, but it does not become so opaque as Jena combustion tubing on prolonged heating. As in No. (4), the proportions given for sodium carbonate and anhydrous borax can be substituted for the figures for sodium carbonate and boric anhydride

Miners' lamp glasses:—

	Parts.
(6) Sand	65·0
Alumina (Al_2O_3)	1·0
Calcium carbonate	0·6
Arsenious oxide (As_2O_3)	2·0
Antimony oxide (Sb_2O_3)	1·0
Potassium nitrate	3·0
Sodium carbonate (Na_2CO_3)	14·0
Boric anhydride (B_2O_3)	24·0

A colourless and fusible glass withstanding rapid changes of temperature exceptionally well

	Parts.
(7) Sand	65·0
Alumina (Al_2O_3)	1·0
Calcium carbonate	0·6
Arsenious oxide (As_2O_3)	2·0
Antimony oxide (Sb_2O_3)	1·0
Potassium nitrate	3·0
Anhydrous borax ($Na_2B_4O_7$)	26·68
Boric anhydride (B_2O_3)	5·5

The same glass as No. (6), but the ingredients have been varied to avoid the use of so much boric anhydride, which is at present apparently difficult to obtain on a commercial scale.

Resistance glass:—

	Parts.
(8) Sand	65·5
Alumina (Al_2O_3)	2·5
Magnesia (MgO)	5·0
Zinc oxide (ZnO)	8·0
Sodium carbonate (Na_2CO_3)	10·2
Borax anhydrous ($Na_2B_4O_7$)	13·0

A glass almost identical in its general behaviour with Jena resistance glass; withstands changes of temperature well, but, like Jena, is not suitable for working before the blowpipe. It darkens and

tends to devitrify; operations—such, for instance, as sealing side tubes into flasks—are difficult, if permanent and neat joints are required.

Formula No. (3), recommended for pharmaceutical purposes, ampoules, etc., may be substituted for the resistance glass with advantage, as the ampoule glass lends itself very well to blowpipe work, and is also especially resistant chemically.

Alternative for combustion tubing:—

		Parts.
(9)	Sand	72·0
	Alumina (Al_2O_3)	10·0
	Calcium carbonate	11·0
	Magnesia (MgO)	0·5
	Potassium nitrate (KNO_3)	3·0
	Sodium carbonate (Na_2CO_3)	11·2
	Borax anhydrous ($Na_2B_4O_7$)	7·2

This glass is capable of withstanding high temperatures and rapid changes of temperature; works well before the blowpipe and is free from the chief defect of Jena glass, namely, the readiness with which it becomes cloudy and finally quite opaque after prolonged use.

By slight modifications of this formula almost any degree of hardness can be obtained.

In formulas Nos. (8) and (9) substances such as magnesia (MgO) and zinc oxide (ZnO) can be added in the form of carbonates if the actual percentages of MgO and ZnO respectively present in the carbonates are known.

Soft soda-glasses suitable for tubing and for X-ray bulbs:—

		Parts.
(10)	Sand	68·0
	Aluminia (Al_2O_3)	4·0
	Calcium carbonate ($CaCO_3$)	12·8
	Potassium nitrate (KNO_3)	14·5
	Sodium carbonate (Na_2CO_3)	26·0
(11)	Sand	68·0
	Alumina (Al_2O_3)	4·0
	Calcium carbonate	12·8
	Potassium carbonate (K_2CO_3)	10·0
	Sodium carbonate (Na_2CO_3)	26·0

These glasses do not lose their easy-working qualities after repeated heating and blowing, and are plastic over a long range of temperature. They require a temperature of at least 1,400 to 1,500° C. for complete incorporation of the ingredients in order to obtain that homogeneity which is necessary for resistance to rapid changes of temperature and ease of working before the blowpipe.

No. (10), containing potassium nitrate, is considered the better of the two, and is more easily incorporated.

The committee consider that the formulas they have obtained and the work they have done on the various glasses justify them in the opinion that there is now information available for the manufacture of all the important glasses used in the laboratory and for industrial purposes, which have hitherto been mainly obtained from abroad.

THE AIMS AND METHODS OF THE FLY EXHIBITION AT THE ZOOLOGICAL GARDENS.

By L. Henderson Williams.

For some weeks past all the leading newspapers have been preaching on one text—death to the fly. By this time everybody knows that it is righteous to kill flies at sight, but the reasons for this earnest and widespread campaign are not always made so clear as they might be. The Fly Exhibition sets forth circumstantial evidence of the dangerous doings of *Musca domestica* and the blow-flies in ways that cannot be misunderstood, and a visit to the Fly Room in the Zoological Gardens at present cannot fail to afford matter for thought, whether the visitor be an ordinary householder or some one more directly concerned with the public health.

Why the Exhibition was Opened.

All over the country this year there are camps, large and small. The sanitary conditions in them are quite different from urban conditions. There is no water drainage, and the pits, unless very carefully disinfected or otherwise treated, are potential breeding-places of incalculable hordes of flies, besides being attractive to those that do not actually breed in excrement.

Hardly any men are now available for the ordinary removal or dispersion of manurial or vegetable refuse, which will therefore remain, in many places, undisturbed, and in a state particularly favourable to the breeding of flies.

If, in addition, it is realised that pestilence almost inevitably follows war; that there has never been war upon such a scale, nor in which so many countries were involved, in some of which terrible diseases recently were rife; also, that non-biting flies may be of primary importance in the transmission of such diseases as cholera—which may be brought to us by our returning soldiers or by refugees—the necessity for putting the country on its guard against the multiplication of flies will be self-evident. This was the aim which Dr. Chalmers Mitchell and Professor Lefroy had in view in getting up the exhibition.

The Exhibits.

The exhibits may be divided into ten classes. Class I. Things for catching or killing adult flies, such as traps, baits, poisons, sprayers, hand-nets, etc. Class II. Things for killing fly maggots in an early stage in manure or rubbish tips. Class III. Fumigants and disinfectants. Class IV. Proprietary articles, useful in keeping off or killing flies, sent in by inventors or chemists. Class V. Living exhibits illustrating stages in the life-history of flies, and others showing the damage they may do in food, etc. Class VI. Specimens in spirit and pinned flies. Class VII. Models of some bacteria that may be transmitted by flies. Class VIII. Photographs and posters. Class IX. Microscopes and slides illustrative of various points in the structure of flies. Class X. Literature, under which heading comes the most recent research in

fly matters, including the pamphlet written by Professor Lefroy in connection with the exhibition, which is on sale, price 2*d.*, at the Society's offices in the Gardens, and which contains useful information as to how flies carry disease, as well as formulæ of baits and poisons, and directions for setting traps.

Classes V. and VI. will appeal especially to the general public. It is one thing to read or hear that a bluebottle-fly may lay as many as 500 to 600 eggs on a joint if it is left exposed, but it is much more convincing to see the result—500 to 600 maggots squirming in the meat in a horrible fœtid mass.

Again, it not seldom happens that when maids are emptying kitchen waste into the dust-bin they let some small object drop and remain outside. One exhibit shows a dish of such ordinary things—a fresh haddock's head, a marrow-bone, whelk shells, a dead mouse, etc.—which were exposed for a day, or a few hours, and all of which are fly-blown.

The books and microscopes are primarily intended for the use of medical men and public health officers, who will ultimately be responsible for fly control throughout the country.

ADVICE.

The object of the Fly Exhibition is to be useful. It is not contended that it, in its early stage, is a repertoire of all wisdom pertaining to the extermination of flies; nor has it yet by any means reached its possible limit in the matter of exhibits, but it may claim, even now, to be a centre for the diffusion of knowledge, and to be useful, in some direction, to all classes of the community, from the farm labourer to the factory owner.

The abnormal rise in price of many chemicals has made it impossible to recommend as practicable sundry treatments as, for instance, the borax treatment of manure, which, in ordinary times would be strongly advocated. Whenever possible, substitutes are put forward and general advice is given, such as keeping manure covered and darkened to prevent the access of flies, keeping it comparatively dry to prevent their breeding, etc.

Investigations are being conducted the results of which are not yet ready for communication, but which, it is hoped, will make the exhibition increasingly valuable as time goes on. Meanwhile, co-operation is invited from all those practically concerned in fighting flies.

ENGINEERING NOTES.

Big Guns.—"This war has brought home to us the necessity of being ready for war," said Lieut.-Colonel A. G. Hadcock, of Armstrong, Whitworth, and Co., Ltd., at a meeting of the Royal Institution. Lieut.-Colonel Hadcock said the manufacturing capacity of the country had been strained to its utmost. We had to make guns and ammunition in a few months over which other nations had taken the same number of years. Referring to big guns, the speaker said few people were aware of the extensive knowledge of science and art necessary to construct a gun and mounting. In the construction of some guns wire was wound round them, and in a 12-in calibre gun the length of this wire was about 130 miles, and in a 13-in. calibre gun about 140 miles, while in some of the latest guns the length of the wire exceeded 190 miles. Guns were often found to become gradually longer after continual firing. The longer a gun was the quicker it would wear out. The life of a gun depended greatly on the heat of the powder.

The 125-lb. per yard Rails for the Pennsylvania Railway.—The increased weight of American locomotives and their heavier wheels need a corresponding advance in the strength of the rails. It was originally proposed to have a 120-lb. rail instead of a 100-lb. rail, but a little later the company decided to make trials of an unprecedented 125-lb. rail, the change being necessitated by the desire to have a rail which would have a moment of inertia as near 70 as possible. The new 125-lb. rail is, of course, experimental in character, and various steel companies are now rolling small orders. The height is $6\frac{1}{2}$ in. against $5\frac{11}{16}$ in the 100-lb. section; the width of the base is $5\frac{1}{2}$ in. compared with 5 in. The top of the head has a radius of 12 in. instead of one of 10 in. in the 100-lb. rail, and the corner radii are $\frac{7}{16}$ in. in each case. The fishing angles are 18° for the head and 14° for the base, compared with 15° and 13° respectively for the older rail.

Train Dispatch by Telephone. Some years ago, the *Engineer* noted the adoption of this system on the Canadian Pacific Railway. The experiment was tried five years ago on a short run between Montreal and Farnham. To-day, on six thousand miles of the Canadian Pacific Railway, the telephone has wholly superseded the telegraph system for dispatching, and the system is being extended to include the whole of the railway lines and branches. The accuracy, promptitude, and efficiency obtained by the use of the telephone are remarkable. The initial cost of installation is greater than that of the telegraph, but the general superintendent of car service states that the increased efficiency more than offsets the increased cost. On each passenger and freight train there is a portable telephone, which in case of emergency can be attached and connected with the nearest dispatcher's office without delay. In this way the train is never beyond instant connection with necessary authority and help, whereas with telegraphy a skilled operator is always necessary, even with portable apparatus. In ordinary dispatching, where accuracy is of such vital importance, the telephone has a decided advantage. With the telephone there is no delay, no uncertainty, and the train is never beyond the reach of the dispatcher.

Cement Manufacture in India.—We are accustomed to connect Greater Britain with raw materials alone, but the Colonies and India are not only hewers of wood and drawers of water, as the steel from Canada and Australia, and the cotton mills of India remind us. Amongst these industries will be shortly included the making of Portland cement in India. The plant is the property of the Katni Cement and Industrial Co., Ltd., and is expected to turn out from 30,000 to 35,000 tons of cement per year. This will be manufactured by the wet process in rotary kilns driven by electric power. In addition to the cement works, the same company has erected works for the manufacture of roofing, ridge and ceiling tiles, glazed wall and flooring tiles, fire-bricks, glazed drainage pipes, glazed earthenware troughs for carrying electric cables, acid-proof jars, and a number of hospital necessities.

A Large Direct-current Generator. The *Electrical World*, in a recent issue, gives a short description of an exceptionally large generator, built by the Crocker-Wheeler Company, for the Ford Motor Company at Detroit. The maximum rated output is 4,500 kilowatts at 80 revolutions per minute. The output, of course, is large for a direct-current generator, but it is not a record. Owing, however, to the very low speed, the dimensions of the machine are exceptional. The total weight, including shaft, is about 135 tons. The outside diameter of the frame is 22 ft. 6 in., and the distance across the base 25 ft. 8 in. There are thirty main poles, and thirty inter-poles bolted to the inside of the magnet frame. In building the machine, the makers had to consider the question of transporting it to its destination, and the casting had to be split, in order that it might pass through the railway tunnels.

The Panama Canal Defences.—The following particulars are from a lecture delivered by Major E. P. O'Hern, at the Coast Guard Artillery School, Fort Monroe, Virginia, of which a summary is given in the *Journal of the United States Artillery*. The Panama Canal defences will embody 16-in. and 14-in. guns, on disappearing carriages, 12-in. mortars and 4·7-in. howitzers. The 16-in. gun of 35 calibres has a range of 18,600 yards, at 15° elevation. It will be mounted at a considerable height above sea-level, which will increase the range. The weight of the projectile fired by this gun is 2,400 lbs., the weight of the charge being 660 lbs. The 14-in. guns are 40 calibres long, and have a muzzle velocity of 2,360 ft. per second and a range of 19,360 yards. These are wire-wound guns, with jacket and B. tube of nickel steel. The weight of the projectile is 1,660 lbs. The 12-in. mortars are wire-wound. They have a muzzle velocity of 1,800 ft. per second, and a range of 19,000 yards, and are the largest pieces of ordnance of this class so far employed in the United States defences. The 4·7-in. guns are primarily intended for the defence of the locks, but extra pedestal mounts will be supplied at the ends of the Canal, so that they may be quickly concentrated at either terminal. These howitzers fire 60-lb. shrapnel, and have a muzzle velocity of 1,300 ft. per second, and a range of 10,000 yards.

Buffer Stops: a Frictional Device.—Buffers of various types have been employed to bring a train entering a terminal station at an excessive speed to a stop, but the *Times Engineering Supplement* states that the problem of design is complicated by the fact that, while the buffer must be capable of stopping the train, the result must be accomplished without serious damage to the buffer itself or harm to the train. A buffer recently invented in America is not secured rigidly to the rails at their ends, but is designed to slide upon them when the momentum of the train exceeds a certain predetermined amount. The essential portion of the buffer consists of two long shoes or tapered friction rails that rest upon the track. The train rides upon these shoes and strikes a plunger projecting from a pneumatic cylinder if it is not stopped in time. The air cushion behind the plunger is relied upon to retard the train's motion, but if it is unable to do so the whole buffer slides along the rail until the friction between it and the rails is sufficient to overcome the momentum of the train. In a test of this buffer a train weighing 1,000 tons, and travelling at a speed of three miles an hour, was brought to a standstill without displacing the buffer. At four miles the buffer slid nine inches, and at eight miles the displacement of the buffer was three feet, and at thirty-two miles, forty feet.

The Corrosion of Condenser Tubes.—Mr. E. Bates, White Bay Power-house, Sydney, N.S.W., has sent to *Engineering* a copy of a paper on this subject, read by him before the Electrical Association of New South Wales in 1913. In this paper Mr. Bates states that the exceedingly serious corrosion of condenser-tubes experienced at the Ultimo Power-station of the Sydney Tramways had been completely checked by the simple procedure of painting the whole of the interior of the cast-iron water-boxes with an anti-corrosive paint. Following the success at Ultimo, the same procedure was adopted with equally good results at the power-station of the Adelaide tramways, where much trouble had been experienced from condenser-tube corrosion. Similar expedients, including electrolytic methods, which failed after a time, were tried. It is therefore interesting to learn from Mr. Bates that his system is still in use at the Sydney power-stations, and with excellent results. During the fifteen months which have elapsed since his paper was read, the number of tubes removed from the two older 5,000-kilowatt condensers has, Mr. Bates informs us, not exceeded three per month, whilst before the Bates' method of protection was adopted it was not uncommon to lose 150 tubes from one condenser in a single week.

OBITUARY.

George Frederick Pollock. — Mr. George Frederick Pollock died at his residence at Hanworth on the 19th inst., at the age of ninety-four. Born in 1821, the third son of the late Lord Chief Baron Pollock, he was educated at King's College, and called to the Bar in 1843. For nearly fifty years he was a Master of the Exchequer Court and Supreme Court, and King's Remembrancer.

In addition to his legal knowledge, Mr. Pollock was well versed in many branches of science. He was deeply interested in mechanics, and before he left the Bar he had become well known as an arbitrator in patent cases. He made a close study of watches and clocks, and did some excellent work as an astronomer. The *Times* recalls the fact that he was asked by his friend, John Murray, to read "The Origin of Species" as it passed through the press, and it was on his advice that Murray doubled the edition.

Mr. Pollock was elected a member of the Royal Society of Arts in 1905.

John Edward Parsons. -Information has been received of the death of Mr. John Edward Parsons, which took place on January 15th. Mr. Parsons was born at New York in 1829, and after being educated at New York University he was called to the Bar in 1852. He occupied a number of important positions: he was director of the Metropolitan Trust Company, a trustee of the Bank for Savings, President of the Women's Hospital, of the General Memorial Hospital, and of the Cooper Union for the Advancement of Science and Art. He took a deep interest in the work of a number of American learned societies, including the American Museum of Natural History and the Metropolitan Museum of Art. He was elected a member of the Royal Society of Arts in 1906.

GENERAL NOTES.

Medicinal Plants.—Fifty years or so since, at Milcombe and Bodicote, says the *Banbury Advertiser*, plants used in medicine were cultivated —rhubarb, henbane, the poppy, and roses—with some amount of success. Plants used in dyeing —woad, the dyers' rocket and others—lost place long years before that. Amongst the bitter lessons of the war is the failure of the foreign supplies which had displaced the British products. Hence we read that prices have risen twice or three times above normal value, and sufficiency of supply becomes a matter of grave concern. Amongst the plants mentioned by Mr. W. A. Whatmough (Journal of Board of Agriculture, September, 1914) are aconite, anise (grown at Westington, near Chipping Norton), belladonna, caraway, chamomile, coriander, dandelion, foxglove, dill, golden seal, valerian, rhubarb, henbane and poppy, elder, coltsfoot, mullein, marshmallow, and tansy are mentioned amongst a number of other plants now likely to be in demand in the market. Some useful notes on cultivation and the necessary form of preparation for the market are added in the account written. It should not be forgotten that the Botanic Garden (the old physic garden) at Oxford is open to everyone, and that most of the plants named, with the many species of like kind grown in other parts of the world, are to be seen, each kind bearing its name and country. Mr. John Tustian, of Milcombe, and Mr. Rufus Usher, of Bodicote, were growers of medicinal plants in the last century, and previously to that, the Society of Arts awarded two medals, a silver one in 1789, and a gold one in 1794, to William Hayward, of Banbury, for growing rhubarb.

Telephone Troubles in the Tropics.—In a paper recently read before the Institution of Electrical Engineers, Mr. W. Llewellyn Preece described some of the serious difficulties met in telephone engineering in tropical countries. The main troubles are due, not to the heat, but to the damp, and the many natural effects caused by damp heat, the humidity of the atmosphere in many places varying between 80 and 90 per cent. This damp heat produces a marvellous growth of vegetation, so thick that along the sides of country roads there are actual walls of green leaves, perhaps 80 or 100 ft. high, the growth of which is so rapid that they may be cut back one day and grow as high again in the ensuing twenty-four hours, while insect life is as prolific as the vegetation. Lightning, again, has a virulence unknown in this country, and even the wild animals do their best to increase the engineers' difficulties. In some parts, for instance, it is not unusual to have a mile or two of lines wrecked by giraffes, elephants, or monkeys. When the giraffes roaming over the wilds of East Africa come up against a telegraph or telephone line, they have not the sense to draw back or duck their heads, but push on, carrying wires and sometimes poles with them.

Mica in Canada.—Canada is one of the three principal mica-producing countries of the world, the others being India and the United States. The average value of the mica produced annually in Canada during the last ten years has been about $185,000. With the possible exception of Ceylon, Canada is the only country, as far as is yet known, in which the variety phlogopite—or "amber mica," as it is termed in the trade—is known to occur in economic quantities. The mica of commerce is of two kinds—muscovite, or "white mica," and "amber mica." The former commands rather the higher price, as it is softer and more flexible, and generally more suitable for use as an insulator. The Canadian amber deposits, according to the report of the Canadian Department of Mines, are comprised within an area of about 1,200 square miles in the province of Quebec, and 900 square miles in the province of Ontario. The city

of Ottawa, which lies between the two areas, is the seat of the mica industry, and contains all the important works engaged in trimming and preparing the mineral for the markets. The average dimensions of mica sheets do not much exceed 3 ins. × 5 ins., but occasionally plates of enormous size are found. Crystals have been obtained measuring over four feet across, and weighing nearly two tons.

COTTON IN UGANDA.—The cotton industry of Uganda has continued to make remarkable progress. The annual report of the Department of Agriculture states that the area under cotton in 1913-14 amounted to 83,714 acres. The exports were 85,217 cwts. of ginned cotton, valued at £272,366, and 44,130 cwts. of unginned cotton, valued at £45,321. The whole of the main crop of the season was Allen's Long Staple variety. During the present season the same variety is being grown over the greater part of the country, but about 6,000 acres will be planted with a selection of the Sunflower variety produced at the Kadunguru seed farm.

MOVEMENT OF SHIPPING AT THE PRINCIPAL ITALIAN SEAPORTS, 1914.—The total net tonnage of the shipping which entered and cleared at the seventeen principal Italian ports during 1914 is given in an official report recently published by the Minister of Commerce. The ports classed as principal, and given in alphabetical order, are: Ancona, Bari, Brindisi, Caglieri, Catania, Civita Vecchia, Genoa, Leghorn, Messina, Naples, Palermo, Porto Empedocle (Girgenti), Savona, Spezia, Torre Anunziata, Trapani, and Venice. The following figures show the net tonnage of the vessels which entered and cleared at these ports in 1914 as compared with the previous year:—

	1914.	1913.
Entered . .	34,645,000 tons.	39,789,000 tons.
Cleared . .	34,581,000 „	30,898,000 „
Total . .	69,226,000 „	70,687,000 „

showing a decrease of 1,861,000 tons lost as compared with the previous year. The total tonnage of goods handled at those ports during the two years was -

	1914.	1913.
Landed . .	16,121,000 tons.	18,208,000 tons.
Shipped . .	3,830,000 „	4,378,000 „
Total . .	19,951,000 „	22,586,000 „

or 2,635,000 tons less last year than in 1913, chiefly noticeable in the imports.

INCREASING REVENUE OF THE FRENCH CUSTOM HOUSE.—It is satisfactory to note a progressive improvement in the monthly receipts of the French Custom House since the beginning of the current year. In fact, compared with those of the corresponding months of last year, the receipts last January, which had fallen as much as 27 per cent. below those in 1914, and 24 per cent. in February, decreased to only 20 per cent. in March. This is satisfactory evidence of improving trade conditions at the present time.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 31...Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Annual General Meeting.

Geographical Society, Burlington-gardens, W., 8.30 p.m.

TUESDAY, JUNE 1...British Decorators, Institute of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Paper by the late Mr. W. G. Sutherland, on "Some Aspects of the Recent Enquiry into the Use of Lead in the Painting of Buildings," to be read by Mr. A. G. White

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. O. Arnold, "The Evolution of Steel: Influence on Civilisation." (Lecture I.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Rev. W. Weston, "Mountaineering in Japan."

Rontgen Society, Cancer Hospital, Fulham-road, S.W., 8.15 p.m. Annual General Meeting.

Gas Engineers, Institution of, Southport Annual General Meeting, from June 1st to 4th.

WEDNESDAY, JUNE 2...Public Analysts, Society of, at the Chemical Society, Burlington House, W, 8 p.m. 1. Messrs. C. Revis and H. R. Burnett, "The Estimation of Starch in Cocoa by the use of Taka Diastase." 2. Mr. B. Campbell, "The Volumetric Estimation of Ferrocyanides." 3. Mr. Seiichi Ueno, "Corean Beeswax." 4. Mr. R. Bodmer, Determination of β-Naphthol in Lysol and similar compounds." 5. Mr. J. J L. van Ryn, "The Composition of Dutch Cheese."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p m. Mr. C. H. Bothamley, "Carcassone · the Cité and the Basse-ville."

THURSDAY, JUNE 3...Linnean Society, Burlington House, W., 8 p.m.

Chemical Society, Burlington House, W., 8 30 p.m. 1. Messrs. H. Hollings and J. W. Cobb, "A thermal study of the carbonisation process." 2. Messrs. T. M. Lowry and R. G. Parker, "The properties of cold-worked metals. Part I.—The density of metallic filings."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. Ward, "Methods of Presenting Character in Biography and Fiction." (Lecture I.)

FRIDAY, JUNE 4...Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir E. Rutherford, "Radiations from Exploding Atoms."

Geologists' Association, University College, W.C., 8 p.m.

Municipal and County Engineers, Institution of, County Hall, Ayr, 11 a.m. Discussion on the following papers: 1. Mr. J. Bryce, "Suggested Town-Planning Details for Scottish Conditions, with criticisms by some members of the Town-Planning Committee of the Scottish District." 2. Mr. J. McFadzean, "Pressure Scraping 15 miles of Water Main."
2.30 p.m. Discussion on the following papers: 1. Mr. R. Drummond, "Road Work." 2. Mr. A. Stevenson, "Description of Experimental Stretches of Road laid in the Ayr District, Ayr County, and Meteorological Station in connection therewith." 3. Mr. W. A. Macartney, "Municipal Housing." 4.15 p.m. Visits to Municipal Works, etc.

SATURDAY, JUNE 5...Royal Institution, Albemarle-street, W., 3 p.m. Professor R. S. Rait, "Mary, Queen of Scots, and Queen Elizabeth." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,263. VOL. LXIII.

FRIDAY, JUNE 4, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

SPECIAL LECTURE.

A meeting of the Society was held on Thursday, May 6th, 1915; LORD SANDERSON, G.C.B., K.C.M.G., in the chair.

THE CHAIRMAN, in opening the meeting, said that about two months ago the Society took advantage of the presence in this country of M. Paul Lambotte, the Director of Fine Arts of the Ministry of Sciences and Arts of Belgium, to offer him an invitation to deliver the Aldred Lecture. He was good enough to accept the invitation, and chose as the subject of his lecture the development of the Belgian school of painting. He (Lord Sanderson) had the honour of taking the chair on that occasion, and he felt at the time that, interesting as the lecture was, it would not be altogether complete unless on a future occasion a supplementary lecture was delivered upon the modern school of Belgian sculpture, a school which was quite as important as the school of modern Belgian painting. He would never have thought of suggesting that M. Paul Lambotte should come again to the Society for that purpose, but M. Lambotte had been kind enough to volunteer to do so, and the Society was again honoured by his presence. They were greatly indebted to him for his kindness.

The lecture delivered was—

CONSTANTIN MEUNIER ET LES SCULPTEURS BELGES DE SON TEMPS.

Par PAUL LAMBOTTE,

Directeur des Beaux Arts au Ministère des Sciences et des Arts de Belgique.

Mesdames, M. le Chairman, Messieurs,—

Le 11 mars j'ai eu l'honneur d'entretenir les membres de la Royal Society of Arts de " L'Évolution de la Peinture en Belgique " au cours du dix-neuvième siècle. Il m'a paru que cet essai exigeait un pendant, c'est-à-dire une causerie consacrée à la sculpture de notre pays pendant la même période. Je m'en suis ouvert à Sir Henry Trueman Wood, qui a bien voulu entrer dans mes vues. C'est, je crois, un devoir patriotique de tâcher de mettre en lumière notre belle école de sculpture, dont la notoriété a franchi les limites de notre territoire exigu. J'ai pris comme titre de cet entretien " Constantin Meunier et les sculpteurs belges de son temps " parce que la grande figure de Constantin Meunier domine toute notre école et que son œuvre est connu et apprécié universellement. Mais, fidèle au plan qui a guidé mon travail la première fois, j'entends bien encore ne pas isoler Constantin Meunier de tous ceux qui ont préparé, accompagné ou suivi l'épanouissement de son art. Ma tâche sera moins compliquée que pour les peintres, le nombre de nos sculpteurs de marque étant moins considérable, et je pourrai me donner le plaisir de m'attacher un peu plus à chaque personnalité.

La sculpture est un art austère dont le développement est plus lent que celui de la peinture. Une école de sculpture atteint sa période d'efflorescence après que la peinture, dans la même contrée et dans les mêmes conditions de prospérité, est déjà en plein épanouissement. La sculpture est associée à l'architecture Elle lui est d'abord subordonnée. A la longue seulement elle prend une vie propre, distincte. L'œuvre d'art de petites dimensions, destinée à l'ornement de la vie, convenant au goût de l'amateur, est, de préférence, une " chose encadrée " qui se suspend aux parois de la maison. Peu de personnes vont au delà, franchissent le pas qui les amènerait à la compréhension de l'œuvre sculpturale. Cette œuvre, privée des prestiges d'une harmonie de couleurs flatteuses, éloquente par les beautés moins apparentes du galbe, des plans, des volumes, demeure froide et indéchiffrable aux yeux du plus grand nombre. C'est à peine si de temps en temps le buste de marbre, de bronze ou de terre-cuite est préféré au portrait peint, et cette préférence est déjà une indication de culture

artistique plus complète ou de goût instinctif plus affiné. Non pas que je veuille dire qu'une hiérarchie fasse prédominer la sculpture, et j'aime mieux un beau portrait qu'un buste médiocre, mais j'entends que la foule est en somme accessible à la peinture et que la sculpture lui demeure plus impénétrable.

Les œuvres des statuaires, par leur poids, par leur importance, sont peu mobiles. Elles sont malaisées à emballer, à expédier, à exposer. Celles qui remplissent un rôle monumental sont immeubles par destination. La participation des sculpteurs aux expositions est toujours difficile, restreinte, coûteuse. C'est pour ce motif que nos sculpteurs sont moins célèbres à l'étranger que nos peintres et c'est aussi pour ce motif qu'il est désirable de les faire mieux connaître.

Constantin Meunier est une exception, et il a fallu des circonstances spéciales, et même un peu de chance, pour que, de son vivant, il fut réputé hors de Belgique. Ses collègues n'ont pas eu la même bonne fortune.

Heureusement j'ai pu réunir un bon nombre de projections qui vont défiler devant vous sur cet écran. Elles illustreront mes commentaires et vous pourrez associer des œuvres avec les noms de leurs auteurs et les détails que je vous fournirai. Si ingrate pour la peinture—qu'elle prive du charme de la couleur, son principal attrait,—la photographie rend mieux justice à la sculpture. Je pourrai vous montrer des aspects assez représentatifs d'œuvres intéressantes. Sans doute vous ne pourrez juger les divers aspects et les éclairages que chaque aspect comporte; il faudra vous contenter de silhouettes, de formes immobiles, alors qu'en tournant autour d'une œuvre le spectateur, par le jeu des ombres et des lumières et le mouvement des plans, peut au contraire faire bouger et vivre la forme.... Mais votre imagination devra suppléer à ces empêchements matériels.

J'ai, l'autre jour, commencé l'histoire de la peinture belge au moment où la Belgique, en 1830, s'est constituée en royaume indépendant.

L'histoire de la sculpture peut être traitée parallèlement. Toutefois nous avons eu à Bruxelles, tout à la fin du dix-huitième siècle, un statuaire de grand talent, Godecharle, auquel l'école qui va suivre doit évidemment beaucoup. Je ne vais pas consacrer une étude à Godecharle, qui eût une éducation complexe et trahit une heureuse assimilation d'influences différentes, mais je tiens à prendre son nom comme point de départ, avant de citer ceux des plus anciens de nos statuaires, Mathieu Kessels, Joseph et Guillaume Geefs, Eugène Simonis, Charles Auguste Fraikin, pour ne parler que des plus intéressants.

Ces artistes ont orné nos monuments de groupes et de statues. Kessels n'est guère sorti des froids pastiches de l'antique, mais nous devons aux deux Geefs, à Simonis et à Fraikin quelques ouvrages qui ne sont point négligeables.

C'est Guillaume Geefs qui est l'auteur de la statue du Général Belliard placée rue Royale à Bruxelles, à laquelle le panorama de la ville basse met un si beau décor de fond. C'est lui aussi qui a modelé les groupes de la Place des Martyrs, le Mausolée de Frédéric de Merode à Ste Gudule, et plusieurs effigies de Léopold Ier.

Eugène Simonis est l'auteur de la belle statue équestre de Godefroid de Bouillon, des lions qui sont à la base de la Colonne du Congrès, des frontons du Théâtre de la Monnaie.

Et Fraikin nous a donné le monument d'Egmont et de Hornes qui fut longtemps devant la Maison du Roi, Grand' Place, et fut, lors de la restauration de ce délicieux immeuble, transféré au square du Petit Sablon, à l'ombre de quelques arbres.

Ces ouvrages ne demandent pas à être vus de près. On leur réclamerait en vain de la sensibilité de surface, de la saveur d'exécution, de l'agrément en tant que morceaux. Mais ils font bien où ils sont, dans le décor. Ils ont l'ampleur et les silhouettes nécessaires.

C'est en somme de la sculpture qui "remplit des contours," qui est contenue dans un galbe, avec froideur et classicisme, un académisme inspiré des répliques romaines de beaux originaux grecs.

Nous pouvons ne pas nous attarder beaucoup et arriver tout de suite à des artistes plus intéressants.

Je nommerai Paul Bouré, sans m'arrêter, mais je veux attirer votre attention sur les œuvres d'un homme qui fut le premier en Belgique à faire passer dans l'art de la sculpture un frisson de modernité, à donner au travail de chaque surface une valeur précieuse, un intérêt d'exécution.

Paul De Vigne occupe dans notre école une place isolée. Il est comme l'aboutissement de tendances diverses, d'influences étrangères et locales un peu contradictoires: il est classique et très moderne en même temps, il a le goût de la beauté, l'instinct des formes harmonieuses et pures, et il mêle à cela un sens ardent de la vie, une compréhension toute contemporaine du mouvement, de l'action, du transitoire dans le geste souple et coulant.

Formé par l'étude des statuaires florentins, il fait penser parfois à leur élégance, à leur eurythmie. Ses statues, ses bustes de femmes, d'enfants, ont des précurseurs dans l'œuvre d'un Verrocchio, d'un Donatello, mais si nous les examinons de plus près nous constaterons combien chez De Vigne le souci de la forme immobile a fait place au culte de la vie. Les yeux, les bouches sont traités comme par un peintre, dans un parti pris expressif, qui prévoit le jeu de la lumière sur le contour, l'animation du mouvement rendu par des contractions, un jeu de surfaces lisses ou gonflées, frissonnantes et frémissantes, qui déjà annonce Rodin.

Si Paul De Vigne modèle des figures populaires, des types réalistes d'énergie ou de souffrance, il atteint à l'effet par des moyens simples et sobres, une parfaite entente des volumes et de la succession des plans, à laquelle se reconnaît immédiatement le grand sculpteur instinctif et doué.

J'ai cité Rodin tout à l'heure. Il sut apprécier le talent de Paul De Vigne, qui était son ainé de pas mal d'années et il a exécuté de lui un buste magnifique, un buste extraordinaire, exprimant toute la vie pensive de l'artiste par l'ampleur lumineuse d'un front exalté.

Paul De Vigne fit sa carrière à Rome, à Paris et à Bruxelles. C'est à Bruxelles qu'il avait son atelier et qu'il travaillait d'ordinaire. Il naquit à Gand, et sa ville natale a tenu à le glorifier en même temps qu'un autre enfant de la vieille cité flamande, Liévin de Winne, admirable peintre de portraits qui fut l'ami de Paul De Vigne.

A la mémoire de ces deux maitres belges fut érigé au Musée de Gand un mémorial composite tout à fait touchant.

Il est surmonté d'une réplique de la belle statue de "L'Immortalité" que De Vigne avait dédiée au peintre et dont le marbre original est au Musée de Bruxelles. De chaque côté du piédestal sont les bustes des deux artistes— Paul De Vigne par Rodin, Liévin de Winne par Paul De Vigne. Ainsi, unis dans une glorification émouvante et posthume, les deux maitres sont associés pour la postérité.

Paul De Vigne est l'auteur de groupes importants, celui de Breydel et de Koninck érigé à Bruges, d'une belle allure populaire sans aucune vulgarité ; celui qui symbolise "Le Génie de l'Art" sur la façade du Musée Ancien de Bruxelles, avec beaucoup de style et de noblesse ; mais il est surtout lui-même dans une série de délicieux bustes de femmes, d'enfants, d'adolescents, où son instinct de la beauté l'a conduit à des réalisations exquises, sans fadeur ni mièvrerie, et d'une technique admirable.

Parmi les contemporains de Paul De Vigne trois sculpteurs belges, disparus comme lui, méritent une étude: Julien Dillens, Jef Lambeaux, Charles Van der Stappen.

Julien Dillens n'a pas donné toute la mesure de ses dons et n'alla pas jusqu'au bout de son développement. Il fut un malchanceux de la vie et mourut d'ailleurs prématurément, ou du moins sans avoir réalisé, dans la mesure du possible, son idéal. Dillens était spécialement doué pour la décoration monumentale. Toutes les figures qu'il a créées pour les associer à l'œuvre d'architectes furent pittoresques et bien trouvées. Elles ont la proportion, l'harmonie, les lignes qu'il fallait pour "tenir" à leur place et parer une façade ou une attique. Il avait de l'imagination, du savoir faire, il savait improviser des formes heureuses et ornées, avec fantaisie et avec goût. Dillens a modelé des statues et des cariatides pour de nombreux édifices à Bruxelles. Il est aussi l'auteur de belles figures funèbres, de nombreux portraits. On cite parmi ses œuvres les plus heureuses: le groupe "La Justice," "Le silence de la tombe," "Génie funèbre." Mais il a aussi aimé la joie et réalisé des œuvres d'une inspiration bien différente—"L'Allegretto," entre autres.

Jef Lambeaux a joui en Belgique d'une notoriété extrême, et jusqu'au moment où Constantin Meunier fut enfin admis et consacré, il était certes le plus populaire de nos sculpteurs. Anversois comme Dillens, Lambeaux eut des débuts éclatants, et dans quelques morceaux— "Le Baiser," qui est au Musée d'Anvers—ou la fontaine de Brabo—ou le buste magistral intitulé "Imperia"—il sut allier une extrême liberté de mouvement avec la saveur du métier et l'entente grandiose des plans ménageant des coulées de lumière et d'ombres.

Sa gloire fut telle un moment que le gouvernement belge lui commanda, d'après un carton qu'il avait composé, un énorme bas-relief de marbre représentant "Les Passions Humaines." Un édifice fut érigé tout exprès pour abriter l'œuvre dans le Parc du Cinquantenaire à Bruxelles.

Il y eut des démêlés vaudevillesques, d'ailleurs, entre le sculpteur, l'architecte, de très grand talent, chargé des plans de la construction, et le gouvernement, qui, après avoir commandé l'œuvre, s'effraya de son audace et tint longtemps l'édicule achevé fermé aux visiteurs.

C'est une œuvre étrange, mal composée sans doute, où les passions charnelles semblent

prédominer absolument sur les intellectuelles, mais dont certains morceaux sont absolument remarquables. Je rappelle aussi le " Dénicheur d'Aiglons," un succès de la jeunesse de Lambeaux.

On a de lui plusieurs groupes de " Lutteurs," très véhéments.

En vieillissant l'artiste se laissa entraîner à une préoccupation un peu exclusive de sujets lascifs et débridés. Son " Ivresse," sa " Folle Chanson," son " Faune Mordu," et d'autres, plus petits d'échelle et d'allure commerciale, ont fait scandale sans que toujours leur mérite de composition ou de modelé put compenser leur licence. La verve de Lambeaux semblait devenue un peu artificielle et voulue, sa force tournait à l'enflure, à la déclamation. Quand on voulut faire une exposition posthume de ses œuvres dans le but pieux de le bien glorifier en ne mettant sous les yeux du public que de très bonnes choses, je dois convenir que la tâche parut ardue et le choix très limité, mais il reste quelques ouvrages de lui qui sont tout à fait de premier ordre et bien personnels.

Chez Charles Van der Stappen la personnalité fut moins marquée, et l'on sent du flottement entre des influences diverses. Revenu ébloui d'Italie il créa d'abord des statues d'allure presque florentine : son " Jeune Homme à l'Epée," du Musée de Bruxelles, son " David "— pour arriver peu à peu, sous l'influence évidente de divers confrères : Lambeaux, quand il compose le groupe de lutteurs intitulé " Ompdrailles " (d'après le roman de Cladel) : Dillens, quand il improvise une décoration pour une pièce d'eau à l'exposition de 1897 à Bruxelles (non exécutée et détruite) : mais surtout Constantin Meunier, quand il entreprend un monument à "L' Infinie Bonté." Il fait aussi penser parfois au sculpteur français Jean Carriès. Van der Stappen est personnel dans quelques très beaux bustes, portraits pleins de vie et d'accent, les meilleurs morceaux qu'il ait signés, " Le Poete Verhaeren," " La Zélandaise," " M. Philippson père," " Le peintre Sacré."

Ces trois artistes furent des contemporains de Constantin Meunier et furent un peu rejetés dans l'ombre quand enfin le succès vint à ce maître.

Vous n'ignorez pas, mesdames et messieurs, que Constantin Meunier est arrivé très tard à la gloire. Il a longuement lutté dans l'isolement et dans l'incompréhension avant d'être enfin apprécié. Il a fait, pendant des années, de la peinture, cherchant sa voie, intéressant certes par la portée morale de ses œuvres, mais incomplet, incertain, tentant des essais divers. On a de lui " L'Enterrement d'un Trappiste " (Musée de Courtrai), " St. Sébastien," " Le Martyre de St. Étienne " (Musée de Gand), " La Salle St. Roch."

Sous l'influence de Charles Degroux Meunier s'était consacré aux sujets exaltés et pénibles. Son art était sévère, rebutant, malgré la grande bonté compatissante qui l'inspirait toujours.

En 1880 Meunier peignit pour une décoration éphémère de salle de fêtes un grand panneau, " La Fonte de l'Acier," qui semble avoir enfin fixé et orienté sa carrière.

Camille Lemonnier avait annoncé qu'après J. F. Millet, le premier interprète sincère et ému du paysan, l'ouvrier des usines trouverait à son tour son peintre. Camille Lemonnier a certes, avec la divination d'un grand critique d'art, aidé Constantin Meunier à découvrir enfin et à creuser son propre sillon. Lemonnier a conté cet épisode que je vous demande la permission de vous lire :

" Constantin Meunier approchait de la cinquantaine quand je le connus. Sa vie avait été rude, secouée d'assauts. Il penchait déjà cette épaule sur laquelle depuis pesèrent la douleur et le travail. Un art sévère mais sans gloire le vouait à une destinée qui tardait. J'eus la pensée de lui demander des dessins pour les chapitres de ma ' Belgique ' sur la contrée industrielle." (Ceci est une inspiration admirable de l'homme de lettres, en quelque sorte le coup de pouce de la destinée pour l'artiste. Mais je laisse la parole à l'auteur :) " Son âme grave et pitoyable prit ainsi contact avec le Pays Noir, comme le premier je l'appelai. Un jour nous montâmes à la terrasse du château de Mons. Sous un lent et incessant déluge de charbon l'air s'estompait de teintes fuligineuses qui décoloraient la tiède après-midi. Une suie éternellement projetée des hautes cheminées recouvrait dans un remous d'incessantes fumées des campagnes anémiques et dévastées. La sensation fut si forte de nous trouver brusquement devant ces horizons calcinés au bas desquels en tous sens s'étageaient des buttes sombres, que nous demeurâmes longtemps sans parler. C'est que de l'endroit élevé d'où nous dominions la grande plaine s'apercevait le cœur même de la région charbonnière.

" L'artiste, qui allait devenir le pensif et sensible introducteur des plèbes dans l'art, à peine connaissait le pays pathétique qui devait être pour lui la cause d'une expression nouvelle d'humanité. Ce moment, dans sa vie, eut une gravité émouvante. Il décida de sa gloire ;

il ouvrit l'art à tout le peuple farouche qui attendait dans l'ombre.

"De sombres et puissants dessins tout à coup firent voir le grandissement qu'à travers une forme d'art pouvait prendre le labeur industriel.

"En 1882 une exposition d'œuvres de Constantin Meunier, peintures et dessins (pas de sculptures encore), précisa la portée de ses initiatives.

"Fusains colorés comme des peintures, dessins enlevés en deux coups de crayon, mordantes et tumultueuses pochades. Partout on sentait la notation exacte, un souci constant des valeurs que donne le passage rapide du jour à la nuit, une attention qui ne se lassait pas pour saisir le mouvement dans son intensité et sa mobilité. Ce fut l'observation d'un esprit très moderne. Nulle trace de sensiblerie dans l'ouvrier tel qu'il le peignait, héroïque et grossier, accomplissant ses périlleuses besognes sans penser à la mort qui est au bout." (C. Lemonnier.)

Meunier donna alors d'autres toiles, "La Descente des Mineurs," "Le Pays Noir," "Le Creuset"—qu'il transposa plus tard en sculpture et qui devint l'un des bas reliefs du "Monument au Travail," dont je vous parlerai bientôt —"L'Accrochage," "Les Hiercheuses," "L'Hécatombe" que sais-je !

Il allait bientôt se donner enfin à la sculpture, mais un intermède encore devait l'en détourner momentanément.

Meunier avait été le directeur de l'école de dessin de Louvain. Toujours besoigneux, le traitement insuffisant ne lui permettant pas de vivre, il avait sollicité du gouvernement belge un subside sous forme de mission. Le gouvernement lui accordait enfin la commande d'une copie du curieux tableau d'un vieux maitre flamand, Pedro Campagna, qu'il fallait aller peindre à Séville.

L'Espagne détournait momentanément Meunier du Pays Noir. Il devait en revenir après plusieurs mois, rapportant la copie attendue—ouvrage médiocre—et des esquisses, des croquis dont il allait tirer ses "Cigarières de Séville," une toile unique dans son œuvre, conservée au Musée de Bruxelles.

Heureusement Meunier oublia bientôt l'Espagne et revint au Borinage, aux ouvriers du fer, du charbon, du verre, dont il allait enfin styliser l'allure brutale et épique.

Ses premières sculptures parurent. Après quelques années elles lui procurèrent la gloire et le commencement d'une fortune. Il n'abandonna pas cependant la peinture et le dessin. Comme l'explique Camille Lemonnier, "la toile, le papier qu'il sabrait de larges traits, étaient souvent la synthèse de l'œuvre qu'il reprenait ensuite pour le marbre ou pour le bronze."

Constantin Meunier n'était pas né pour le bonheur. A peine sorti des torturants embarras d'argent, la mort lui ravissait successivement ses deux fils, accablait une de ses filles d'un mal qui la laissa longtemps invalide. Son grand cœur pitoyable se penchait vers les humbles et, dans les scènes ou les figures qu'il traçait, leur pauvre vie était exaltée, magnifiée, transfigurée par l'expressive éloquence de la bonté et de l'émotion de son âme.

On vit paraître alors cette série de chefs-d'œuvre, "Le Débardeur d'Anvers," "L'Homme à la Tenaille," "Le Marteleur," "Le Puddleur," "La Hiercheuse," "L'Enfant Prodigue," "Le Vieux Cheval de Mine," ce groupe imposant du "Cheval à l'Abreuvoir" érigé dans un square de Bruxelles, et "La Pietà," et "Le Grisou," et tant d'autres, grands et petits, "points de repère dans l'œuvre innombrable où inlassablement Meunier prodigue la vie, la nature et le génie."

La sculpture de Meunier apparaissait au moment où les idées généreuses du socialisme contemporain ouvraient les yeux sur les souffrances des travailleurs et prêchaient la grande pitié fraternelle. C'est un art tout d'inspiration cérébrale dont le pathétique est dû à des qualités d'essence plus haute que les mérites techniques de l'exécution. Sans doute Meunier fut un sculpteur doué. Il eut le sens des volumes, des masses, des ensembles, mais ce n'est pas par la beauté superficielle du travail qu'il s'impose. Il est souvent monotone, un peu convenu dans la répétition de certaines formes, de certains morceaux qui reparaissent sans avoir retrouvé dans l'observation du modèle le rajeunissement indispensable.

On a qualifié la sculpture de Meunier de sculpture de peintre. C'est, je crois, plutôt de la sculpture d'intellectuel, et à côté des œuvres de Jef Lambeaux, par exemple, dont je vous parlais tout à l'heure la différence est frappante : Lambeaux, sans culture, sans sensibilité, magnifique ouvrier créant de la forme vide ; Meunier, réfléchi, intense, poignant, insoucieux du galbe, du charme d'un bel ouvrage bien fait, du goût qui rend précieux chaque pouce carré de la surface d'un marbre ou d'un bronze. Là la sensualité, ici une cérébralité attendrie.

Le "Monument au Travail" fut le couronnement de la carrière de Constantin Meunier. C'est aussi son œuvre la plus considérable et la plus célèbre.

Le titre a du prestige. Les littérateurs n'ont pas manqué de consacrer au "Monument au

Travail" mille commentaires enthousiastes ou ingénieux.

Tout chef-d'œuvre considérable réalisé par un homme de génie dans la maturité de son esprit contient plus de pensée, de sens et de moelle que l'artiste ne l'avait rêvé. Sa portée va au delà, et dans des domaines intellectuels que l'auteur n'avait pas prévus! Meunier, instinctivement, sans le chercher, nous a fait sentir bien des choses qu'il avait comprises, au cours de sa vie, dans la bonté noble et généreuse de son grand cœur et de son doux esprit, mais qu'il ne croyait pouvoir exprimer par de la forme et de la matière.

L'émotion de l'artiste est contagieuse: elle inspire, par une sorte de magnétisme, l'intellectualité de celui qui s'approche respectueusement de son œuvre et cherche à en pénétrer la complète signification.

Meunier mourut avant que les éléments de son "Monument" fussent assemblés. Et depuis sa mort les divers bas-reliefs et statues qui en formeront un jour l'ensemble sont demeurés épars. C'est une histoire étrange et qui vaut d'être contée.

Meunier venait d'achever le modèle du quatrième et dernier bas-relief. Il n'en vit jamais l'exécution en matière définitive; la sculpture des pierres fut réalisée après son décès.

Le "Monument" doit comporter quatre grands bas-reliefs et cinq ou six statues. Je dis cinq ou six parce que plusieurs dispositions architecturales furent étudiées pour l'assemblage des sculptures de Meunier et qu'aucune ne fut définitivement adoptée

Meunier lui-même avait tantôt englobé dans certaines statues l'ensemble et tantôt les avait exclues.

Il avait modelé bas-reliefs et statues sans projet préconçu de les réunir et de faire servir leur groupement à l'expression d'une pensée. Un ou deux bas-reliefs, deux ou trois statues existèrent avant que l'idée du "Monument au Travail" prit corps. Aussi sont-ils tous de dimensions, d'échelles différentes. Et quand Meunier créa la suite complémentaire il mit la même insoucieuse fantaisie à ne pas tenir compte des proportions des premiers morceaux. Ces circonstances n'étaient pas pour faciliter l'assemblage final.

Les éléments essentiels sont les quatre grands bas-reliefs symbolisant le travail de la Mine, de la Métallurgie, de la Moisson, et du Port, ou, si vous le préférez, les quatre Éléments, car dans ce chef-d'œuvre si moderne les conceptions primordiales et simplistes de la plus antique humanité sont manifestes. La Mine c'est la Terre; la Métallurgie, avec le rideau des flammes derrière les ouvriers du fer, c'est le Feu; la Moisson c'est l'Air; et le Port c'est l'Eau!

Les statues complémentaires représentent des travailleurs au repos, le vieillard, l'homme dans la force de l'âge, le jeune ouvrier et la mère, avec ses robustes enfants, qui est aussi la personnification évidente et traditionnelle de l'Abondance ou de la Charité.

Enfin un semeur, dont l'allure symbolise assez l'Avenir et ses promesses, devait couronner le tout de son geste éternel comme les recommencements des saisons sur la terre!

Meunier avait un moment songé à placer le groupe de la mère et de ses fils en avant, au bas des gradins portant la masse monumentale. En ce cas une autre statue d'ouvrier assis eut été incorporée dans l'arrangement.

Au moment où le gouvernement belge traita avec le maître et devint le propriétaire exclusif des sculptures du "Monument au Travail" aucun dispositif n'avait paru satisfaisant et n'avait été adopté. Le contrat portait simplement que les œuvres sculpturales composant le monument seraient réunies et exposées, selon un arrangement à trouver, dans une des salles d'un Palais des Beaux-Arts dont la construction était décidée alors et paraissait devoir être commencée incessamment.

Je dirai tout de suite qu'un vote imprévu du Législateur Belge, annulant une décision antérieure et affectant à d'autres usages des crédits précédemment réservés, fit abandonner l'idée de cette construction et que par ce fait la condition du contrat devint irréalisable; il est, et sera sans doute encore pendant bien des années, impossible de loger le "Monument au Travail" dans une salle spéciale du Palais qui devait s'appeler le Mont des Arts et qui moins que jamais maintenant paraît devoir être réalisé.

Il est assurément souhaitable que le "Monument au Travail" soit enfin érigé *en plein air*—tout le monde paraît d'accord là-dessus.

Les artistes, les hommes de lettres, les critiques d'art sont unanimes, en principe, sur ce point. Restent à trouver l'emplacement et le dispositif. Le gouvernement belge, comme c'était son devoir, s'en est préoccupé. On a préconisé l'érection du chef-d'œuvre à Bruxelles, capitale du royaume; à Anvers, principal port de mer; à Charleroi ou à Mons, centres du pays industriel; à Louvain, en souvenir de l'existence de Constantin Meunier dans cette ville, où il dirigea longtemps l'école de dessin. Il semble bien que

le choix de Bruxelles ait prévalu, que Bruxelles ait obtenu le plus grand nombre des suffrages. Mais dans Bruxelles même, ou plutôt dans l'immense agglomération bruxelloise, qui groupe plus de 600,000 habitants, les sites éligibles sont nombreux ; chacun a ses partisans. Des discussions passionnées se sont élevées. D'aucuns veulent le monument à l'entrée du Bois de la Cambre, d'autres au second rond-point de l'Avenue de Tervueren : promenades larges, élégantes, fréquentées par les oisifs et les étrangers. Elles sont un peu distantes du cœur même de Bruxelles, où des enthousiastes voudraient garder le monument, en plein centre, parmi le mouvement et la vie des affaires ! D'autres encore pensent au quartier du port, car Bruxelles, par ses canaux reliés aux fleuves et à la mer, a un quartier du port, le quartier de Bruxelles port-de-mer, qui d'ailleurs aussi touche aux usines, aux manufactures, aux fabriques des faubourgs populeux.

Le "Monument au Travail" paraît devoir parler aux foules, aux masses ouvrières ; on peut hésiter sur l'opportunité de le situer à l'écart, dans le tranquille recueillement des avenues et des verdures.

Une question plus brûlante est celle de la forme à donner au monument, du dispositif architectural à adopter.

Constantin Meunier n'avait rien décidé. Il avait d'abord songé à un arrangement en façon d'hémicycle et l'on a trouvé un croquis de lui indiquant cette conception.

Puis, à l'époque où Meunier a travaillé avec Van der Stappen à la décoration du Jardin Botanique de Bruxelles, l'idée de l'hémicycle, sous l'influence de Van der Stappen, fut abandonnée. Un architecte viennois fut consulté et fournit une autre idée.

Il est piquant de remarquer à ce propos que Van der Stappen, de son coté, s'empara de l'idée du dispositif en hémicycle pour le projet de son monument à "L'Infinie Bonté" qu'il préparait en ce moment et dont des études et fragments seuls réalisés reflètent une si forte influence de Meunier !

L'architecte viennois préconisait un cube, lourd et massif, portant un bas relief sur chacune de ses faces, une statue à chaque angle, la figure du semeur surmontant l'ensemble.

C'était, sauf respect, quelque chose comme une énorme boîte à biscuits posée sur un socle de gradins et surmontée, en guise de bouton de couvercle, de la statue du semeur.

Le gouvernement belge a essayé les deux combinaisons, des maquettes conformes aux deux conceptions ont été, à grands frais, réalisées en grandeur d'exécution.

En 1905, à l'occasion de l'exposition rétrospective de l'art belge, bien peu de temps après le décès du maître, une apothéose lui fut réservée. Dans l'enceinte de cette exposition, qui résuma tout l'effort de l'art belge pendant trois quarts de siècle, où chaque maître disparu fut rappelé par un ensemble de ses œuvres, Constantin Meunier obtint la part du lion. Plusieurs galeries lui furent exclusivement consacrées. Au centre de la plus grande, l'architecte Acker, un autre grand Belge disparu, avait édifié l'hémicycle portant les quatre bas-reliefs fameux flanqués chacun des statues accompagnatrices. En avant était posé le semeur. Un jeu sobre de degrés, de moulures, de corniches encadrait les magistrales sculptures. Toutes les différences d'échelle, de dimensions, de présentation, dont j'ai parlé, avaient été ingénieusement escamotées. L'ensemble était émouvant de grandeur de simplicité. Chacun dut, en se trouvant tout à coup devant cet éloquent chef-d'œuvre, en ressentir l'effet. Les hommes ôtaient leur chapeau, les femmes se taisaient . . . un instant. On put croire la question résolue. Mais les intérêts en jeu n'étaient point satisfaits. La solution fut paralysée par la résistance des héritiers de Meunier.

Plus récemment Louvain eut une exposition commémorative de l'œuvre de Constantin Meunier. Le gouvernement belge intervint largement dans la dépense. Une nouvelle maquette, conforme cette fois au plan de l'architecte viennois, fut édifiée dans la cour de l'un des principaux instituts, dépendant de l'université. Le chanoine Théry prodigua son dévouement, il paya de sa personne et de sa bourse, sans compter ! Il voulait fixer la forme définitive du chef-d'œuvre et espérait garder à Louvain un exemplaire conforme à la maquette. Bruxelles eût érigé l'autre dispositif, l'hémicycle ; le premier eût montré les bas-reliefs en bronze, le second les bas-reliefs en pierre : la Belgique eût été dotée des deux versions si nettement différentes du "Monument au Travail." Quelle attraction d'art, et quelle curiosité de comparaison offerte !

Hélas ! la maquette de Louvain, comme celle de Bruxelles, fut démontée sans que rien fut résolu.

Mesdames et messieurs, je dois vous avouer qu'un seul homme a parlé jusqu'ici avec une complète et entraînante éloquence de l'art de Meunier et en a mis en lumière toute la signification complexe. C'est mon ami Jules Destrée,

en ce moment retenu en Italie par une mission dont le gouvernement belge l'a chargé. Pour ceux qui l'ont entendu commenter l'œuvre de Constantin Meunier, qui ont gardé le souvenir de son verbe imagé, de sa voix persuasive, de sa pénétration généreuse, j'ai peur de paraître presque sacrilège en touchant, après lui, un sujet qu'il a fait sien.

Je ne l'eus pas traité si les circonstances ne m'avaient paru justifier mon audace.

Je fais apparaître sur l'écran le buste de Constantin Meunier par Victor Rousseau, qui appartient au Musée de Bruxelles. C'est un merveilleux résumé expressif du masque du vieux maître. Rousseau y a travaillé longtemps d'après nature dans l'atelier de Meunier sans parvenir à s'en trouver satisfait. En désespoir de cause un jour il a remporté chez lui la masse de glaise et pendant tout un temps l'a abandonnée dans un coin. Mais la pensée de ce portrait continuait à le hanter et soudain il le replaça sur une selle et se remit fiévreusement à l'ouvrage. En quelques heures il réussit à dégager enfin l'expression synthétique qui caractérise si bien Meunier et à parachever ce magistral morceau.

Puisque j'ai nommé Victor Rousseau je veux tout de suite vous dire quelques mots à son sujet. Malgré qu'il fut très jeune à la mort de Meunier et qu'à ce moment ceux qui, devant la tombe du grand disparu, se demandèrent quels seraient désormais les maîtres de notre école de sculpture, aient dû penser peut-être à des talents plus anciennement reconnus, déjà alors certes on pouvait prédire à Rousseau la magnifique carrière qu'il allait fournir.

Comme Meunier, Rousseau est un sculpteur intellectuel qui n'a jamais fait passer le souci de la forme plastique avant celui de la pensée expressive. Toute œuvre de Rousseau a une portée, un sens, elle donne à réfléchir. On est pris, retenu, intéressé avant d'admirer l'art du sculpteur, éxécutant technique cependant remarquable.

Je n'aurai pas le temps de m'appesantir beaucoup et je vais bien vite vous faire projeter quelques ouvrages de Victor Rousseau. Vous avez eu l'occasion de voir à Londres même des morceaux charmants de lui, bustes, figurines, fragments, d'une grâce fine, jeune, délicieuse. Ce n'est là qu'un côté de l'art de Rousseau. Dans des compositions très importantes, de dimensions considérables, comme les "Sœurs de l'Illusion" (Musée de Bruxelles) ou le "Groupe de la Maturité" (commandé pour une place publique), il sait allier à la perfection de la forme une rare entente de la signification morale à laquelle l'art doit atteindre.

Combien nous sommes loin, devant ces ouvrages si mûris, des figures de "baigneuses" ou de "modèles au repos" dont se contente trop souvent l'imagination un peu courte des artistes, figures très belles souvent, mais inertes, d'une plasticité équilibrée qu'aucune vie intérieure ne fait palpiter.

Voici "Le Liseur," d'une conception toute intérieure exprimant de la réflexion, l'amour de l'étude. Il semble que le front du liseur émette de la lumière!

"L'Homme penché sur le Masque de Beethoven," une œuvre pensive reflétant les prédilections musicales de Victor Rousseau. Je devine que l'artiste lui-même a dû interroger curieusement le moulage du masque de Beethoven et tenter d'y découvrir les secrets de son émouvant génie.

Le groupe de "La Danse," d'un rythme juste et balancé, que l'on peut situer à un plan bien différent de l'admirable et expressif groupe de Carpeaux. Aucune analogie. Carpeaux a traduit avec puissance une allégresse physique, une joie dionysiaque. Chez Rousseau c'est de la mesure, un geste plus cérébral que vraiment physique, une inspiration musicale.

Combien je regrette de ne pouvoir vous montrer le buste exquis de S.M. la Reine Élisabeth. Rousseau a su y enclore tout ce charme, toute cette grâce, toute cette intelligente bonté qui ont irrésistiblement conquis le cœur des Belges. L'attitude actuelle de notre souveraine admirable a achevé d'inspirer au monde entier un respect sans bornes, une indéfectible affection à l'endroit de cette frêle et si ferme héroïne! Victor Rousseau a fait du buste de la petite Princesse Marie José un morceau achevé de souple et juvénile espièglerie. Je n'ai jamais, à l'occasion de quelqu'exposition à l'étranger, montré ce morceau ravissant à une femme sans qu'aussitôt elle se soit mise à caresser, à flatter d'un geste maternel, le petit dos, la nuque délicieuse de la charmante enfant.

Victor Rousseau est aussi l'auteur d'un buste du Roi Albert. Je ne crois pas qu'il soit d'une ressemblance matérielle très exacte, mais j'y lis la transcription révélatrice de ce caractère dont l'affirmation a depuis émerveillé le monde. Comment exprimer par le travail d'un outil dans le marbre le prestige que prend une figure humaine dans des circonstances si particulièrement tragiques et qui mettent en lumière la noblesse d'un libre esprit, l'énergie d'un cœur indomptable, ce sentiment du devoir, cette

abnégation de soi-même, cette simplicité poussée jusqu'à l'héroïsme, qui ont forcé l'enthousiasme du monde civilisé ?

Mesdames et Messieurs, en cessant de vous parler de Constantin Meunier j'aurais dû chronologiquement vous nommer des artistes moins jeunes au moment de la mort du maître que Victor Rousseau, et déja en possession d'une grande et légitime renommée, Thomas Vinçotte, le Comte Jacques de Lalaing, G. De Groot, L. Mignon. . .

Vinçotte est notre grand statuaire officiel. Mais bien différent de beaucoup de statuaires officiels Vinçotte a un talent très élevé, très libre, très élégant. Il ne sacrifie jamais aux banalités conventionnelles, il demeure sincère et vrai, original dans chacune de ses conceptions. Et il cherche toujours à faire mieux, à faire nouveau, à faire plus intense et plus ressenti. Même il lui arrive de se tromper, mais il ne lui arrive jamais d'être médiocre ou indifférent, ce qui n'est pas—n'est-il pas vrai ?—en général le propre d'un statuaire officiel.

Je suis obligé d'aller un peu vite et je ne puis me donner le plaisir de commenter les œuvres principales de Vinçotte, ses groupes décoratifs, ses statues et ses "memorials," le fronton, très discuté, du nouveau Palais Royal de Bruxelles, et toute la série si admirable de ses bustes.

En voici quelques spécimens : "La Musique," bas-relief du Palais des Beaux-Art de Bruxelles, d'une eurythmie antique; ce "Groupe," du Château Royal d'Ardenne (torse Triton) ; "Le Dompteur de Chevaux," placé près du Bois de la Cambre à Bruxelles ; "Le Monument De Naeyer" ; et ces bustes, "Catilina," "Le professeur Chandelon," "Léopold II.," "Le Roi Albert."

Chez Vinçotte le portraitiste est incomparable. Il excelle à mettre en lumière les traits distinctifs du modèle ; il est révélateur du caractère et du tempérament, jusqu'à l'indiscrétion parfois.

Le Comte de Lalaing, dont j'ai eu le plaisir de vous citer, lors de ma causerie sur la peinture, les tableaux, les portraits et les grandes fresques décoratives, occupe une place très en vedette dans notre école de sculpture. Héritier d'un des plus beaux noms—et des plus anciens—de l'histoire de Belgique, ce gentilhomme s'est voué à l'art avec une passion extrême. C'est un grand laborieux ; le total de son œuvre est déjà incommensurable et il est littéralement affamé de travaux nouveaux. Sa générosité égale son désintéressement et parfois ses confrères lui ont reproché de gâter le "métier" par excès de délicatesse. Presque toujours le statuaire se contente d'une indemnité pour les frais matériels de l'exécution de ses œuvres en marbre ou en bronze, et fait don de son travail personnel.

J'ai eu le plaisir de pouvoir mettre sous les yeux du public britannique, à l'exposition d'hiver de la Royal Academy, quelques fragments de l'œuvre du Comte Jacques de Lalaing, en même temps que des ouvrages de plusieurs de nos sculpteurs, dont le vif intérêt, le niveau élevé d'art, n'a pas échappé aux connaisseurs.

Voici "Le Génie Funéraire" du Comte de Lalaing, dont la tête seule a été exposée ici. C'est une conception de très belle et hiératique allure ; "Tigre et Serpents," le prototype d'une série d'œuvres mettant en lumière les souples luttes ou les jeux des félins. (Base de mât électrique.)

Voici une œuvre de M. Guillaume De Groot, sculpteur puissant auquel on doit divers monuments et statues. ("Le Travail.") Et un groupe de feu Léon Mignon, spécialiste de la sculpture d'animaux, qui a créé les modèles d'une robuste décoration placée à Liege, sa ville natale. ("Dompteur de Taureaux.")

Je suis obligé d'aller trop vite et de citer seulement les noms des artistes, en projetant quelques aspects de leurs œuvres sur l'écran. La plupart vous sont connus, ils ont eu récemment des œuvres aux expositions anglaises, tous sont en pleine production, ils n'ont pas réalisé encore tout leur devenir, nous pouvons leur faire crédit.

Voici Jules Lagae, une façon de gothique moderne dans ses études d'humanité si parfaitement observées et réalisées—"Mère et Enfant," "Père et Mère," "Guido Gezelle," le curé poète qui a consacré à sa Flandre natale des pages si parfumées, d'un sens si frais et si sain de la nature.

Charles Samuel, dont le monument à Charles De Coster a marqué avec éclat les débuts.

Paul Dubois, robuste et harmonieux, un des coryphées de l'art wallon—"Le Penseur."

Josué Dupon, qui consacre à l'étude des animaux son beau talent décoratif "Vieux chevaux."

Fr. Huygelen, dont le Musée de Cardiff vient d'acquérir une œuvre intéressante. Voici un de ses bas-reliefs—"Les Heures."

P. Braecke, dont je n'ai malheureusement rien à vous montrer, mais dont le groupe de "Femmes de Pêcheurs," en pierre grise, fut très admiré à la Royal Academy cet hiver.

Je n'ai rien non plus de Jean Hérain, l'excellent statuaire à qui nous devons le beau bas-

relief du fronton de la nouvelle école militaire à Bruxelles, ni d'Aloys De Beule, un Gantois apprécié.

Voici Georges Minne, imagier naif comme un primitif au début de sa carrière; en possession d'un métier si souple, si expressif, si fort, un des hommes en vue de notre école à cette heure.

Fernand Khnopff, sculpteur tout à fait occasionel, mais dont aucun ouvrage n'est indifférent et qui a touché à tout avec goût et imprimé aux moindres œuvres de ses doigts la marque de son énigmatique et raffinée personnalité—"Sybille." "Jeune Femme."

Je devrais consacrer toute une étude à notre école de Médailleurs, à Godefroid De Vreese, à Paul Bonnetain, à Louis De Smeth, à Paul Wissaert et à bien d'autres. Je ne puis qu'indiquer leurs noms en passant.

Mesdames et Messieurs, vous pourrez voir la semaine prochaine à l'exposition de la Société Internationale des Sculpteurs et Peintres, Grosvenor Gallery, une série d'œuvres belges encore inédites à Londres. Nos peintures remplissent une salle, et deux des plus jeunes d'entre nos sculpteurs, MM. Rik Wouters et Marnix d'Haveloose, affirment là audacieusement leurs jeunes talents d'avant garde, leurs recherches un peu déconcertantes, un peu brutales parfois, mais dont on ne saurait dénier la valeur.

A l'exposition d'été de la Royal Academy, qui vient de s'ouvrir, l'école belge de sculpture est représentée par une œuvre maitresse d'Égide Rombaux, un marbre admirable, intitulé "Premier Matin."

M. Rombaux est, parmi nos sculpteurs qui vont atteindre bientôt leur maturité, un des plus personnels et des plus intelligents. Son art est d'un grand style, d'un rythme libre et fort et son exécution est pleine de saveur. L'apparition de ce marbre à la Royal Academy est l'occasion d'une manifestation confraternelle qui honore aussi hautement les artistes britanniques que l'art belge et dont je ne saurais assez mettre en lumière le caractère exceptionnel. Des sculpteurs, des peintres membres de l'Académy ont pris l'initiative d'ouvrir entre eux une souscription pour acquérir l'œuvre importante de Rombaux et l'offrir à la Nation. Le marbre trouvera sa place au Musée Victoria et Albert à Kensington, non loin de l'admirable série des chefs-d'œuvre de Rodin donnée par le maître.

Mesdames et messieurs, je veux voir, et les artistes belges si nombreux ici voient avec moi, dans ce geste magnifique des artistes britanniques en l'honneur d'un confrère belge, l'hommage collectif d'estime et d'admiration d'une École envers une autre École, une justice rendue par des juges dont le suffrage est sans prix. Je sais que les souscriptions affluent, malgré la rigueur des temps, dont les artistes plus que personne souffrent en ce pays, et que beaucoup s'imposent un réel sacrifice.

Il m'est impossible d'exprimer la noblesse, la dignité de cette pensee, de cette communion esthétique! Seuls des artistes pouvaient la concevoir, elle est d'une beauté morale supérieure que vous comprenez, que vous sentez, malgré la pauvreté de mon discours et l'impuissance de mon langage. Elle nous est une consolation, une revanche des outrages que nous souffrons d'autre part. Je ne pourrais mieux terminer cet entretien sur notre école de sculpture belge qu'en disant aux promoteurs et aux souscripteurs de cette manifestation exaltante la gratitude collective de tous nos artistes, notre gratitude émue et profonde, notre gratitude éternelle.

The Chairman (Lord Sanderson, G.C.B., K.C.M.G.) said that he had been presiding over a lecture and not a meeting, and that circumstance, to use a phrase of the late Lord Granville, had saved him from the compilation of some insipid remarks. But he was sure all present would wish to join with him in thanking M. Paul Lambotte for his most interesting lecture, full of instruction and not devoid of wit, and also for the very admirable series of photographs with which it had been illustrated. M. Lambotte had been working under great difficulties. In any case a collection of the kind that had been shown on the screen was not prepared without a good deal of trouble, but on the present occasion it had been much greater than usual. He happened to know that (although probably the author was not aware how he was acquainted with the fact), because he always preferred, when he took the chair on such an occasion, to learn something about the subject beforehand. He had appealed to the Director of one of our great Museums to let him see some book which would give him a slight knowledge of the works of Belgian sculptors. The Director replied that he would be delighted to show him the collection of books which M. Paul Lambotte had himself extracted from the library for the purpose of consultation, and he (Lord Sanderson) was astounded at the size of the pile. He was sure all present felt they were under a real obligation to M. Paul Lambotte for the pains he had taken to procure suitable illustrations, in addition to favouring them with the fruits of his great experience and knowledge; and he could also assure M. Lambotte that everyone present had heard with much sympathy the kind words with which the lecture concluded.

POULTRY INDUSTRY IN THE PHILIPPINES.

The consumption of eggs in the Philippines is remarkably large. There are no reliable statistics from which to compute the number of chickens annually bred in the islands, but the total is certainly very great. Throughout the country, remote from the larger port cities, chickens and eggs form a considerable portion of the diet of the people who can afford more than rice and fish. The native chickens are small, and the eggs are therefore small; but the native hen is a good layer, and the country produces a large number of eggs in proportion to the hens kept. In spite of the shortage of eggs in the country and the yearly necessity of importing millions of dozens, more attention is given to breeding cocks than to breeding hens. The fact that no Filipino of the common class regards himself equipped for living without at least one male chicken explains why the islands, although raising so many chickens, still import eggs. As in all cock fighting countries, the fighting bird in the Philippines is a personal pet, which the owner carries about during practically every idle moment of the day, and on which he lavishes a great amount of care. In recent years, according to a correspondent of the Bureau of Foreign and Domestic Commerce of the United States, attempts have been made to introduce larger breeds of chickens into the Philippine Islands, but only with moderate success. The imported breeds require much greater care and are less able to endure their environment when left to shift for themselves, as is generally the case with the native hens. Several attempts have been made recently by Europeans and Americans to breed chickens and eggs for the Manila market, but without great success. The difficulty has been that these experimenters have used imported breeds in order to have larger eggs, and the fowls have not done well, being more subject to disease than the native varieties. It is difficult to get fresh eggs in the market in any of the larger centres of population. In Manila most of the eggs on the market are imported from China. Of these from 20 to 40 per cent are unusable. So far as can be learned, there are no incubators used in the islands, certainly none on the market, except as they may be ordered direct from abroad. Chickens are usually retailed alive according to size. Ducks are bred to some extent, and a few geese. Duck eggs are rarely found in the market except as "balutes"--that is, eggs on the point of hatching, boiled, a form in which eggs are commonly eaten by the Filipinos. They are sold for lunches at all railway stations and at other points where large numbers of people assemble.

PEANUTS IN NORTHERN ARGENTINA.

The area under peanuts in Argentina increased from 33,273 acres in 1895 to 80,309 acres in 1907, but by 1912 it had decreased to 34,668 acres. The following table shows the area by provinces in the three years mentioned :—

Years	Santa Fe.	Entre Rios	Corrientes.
1895 . .	16,136	10,109	4,653
1907 .	45,714	21,498	8,649
1912 . .	21,992	5,189	1,448
Years.	**Cordoba**	**Other Provinces**	**Total.**
1895 . .	818	1,557	33,273
1907 . .	1,730	2,718	80,309
1912 .	741	2,298	34,668

The shells of Santa Fé peanuts constitute 22·82 to 30·79 per cent., and those of Entre Rios peanuts, 24·8 per cent. of the total. The principal constituents of the kernels are as follows :—

Kinds of peanuts	Water.	Protein	Fats
	Per cent.	Per cent.	Per cent.
Santa Fé . .	5·261 to 6·504	24·312 to 34·887	40 780 to 47 530
Entre Rios .	5·80	31·80	44 55

Over 5,000,000 lbs. of peanuts were exported from Argentina as far back as 1866, and considerable quantities appear to have been exported up to about ten years ago. Customs returns covering the years from 1907 to 1913 show that, except small quantities in 1908, no peanuts were exported during the period.

The principal region for peanuts is the northern part of the Province of Santa Fé, particularly the Departments of Garay and San Javier. A considerable proportion of the yield of this district is used for oil by factories situated near the producing centres. Peanut oil is also made in the Province of Entre Rios. According to a report by the United States Consul at Rosario the northern part of Santa Fé in recent years has suffered severely from heavy rainfall, which has, of course, affected the peanut crop. The present crop, which has now been harvested (during March and April), will probably be short.

Peanuts for oil are sold at an average price of ¾*d.* to 1*d.* per lb. They are also in demand for food purposes. Small nuts of inferior quality sell wholesale at about 1¼*d.* per lb. The best grade of native nut sells at 1¾*d.* per lb. wholesale.

DEMAND FOR LEATHER GOODS IN CHINA.

With the introduction of foreign ideas the Chinese are using more leather goods than ever before, and there is a constantly increasing demand for the foreign product. This is due partly to the adoption of Western dress, and partly to the increased military activity which is noticeable in every part of China. Foreign shoes are becoming more and more popular among the Chinese, and since they travel about a good deal more than formerly they are commencing to use leather trunks, suit-cases, hand-bags, and hat-boxes to a great extent. Foreign saddlery of all kinds is also enjoying a wider sale, and leather belts and straps for wrist watches are coming more and more into vogue. Not only are these articles used by the increasing military population, but leggings, cartridge cases, and other articles are enjoying a wider sale. Although the Chinese are able to imitate the leather goods from abroad, says the American Consul at Chungking, the materials which they use are, as a rule, of very inferior quality. The native leather is poorly tanned, and is generally odoriferous. It is spongy and easily affected by moisture. The wearing quality is poor, and it generally has a dull and lifeless appearance.

The Japanese have not been slow to take advantage of the demand for leather goods of foreign manufacture, but the goods which they sell have not been altogether satisfactory to the Chinese. Frequent complaints are made with regard to the quality, durability, and the appearance of their products, and the prices, while comparatively low, do not mean economy in the long run. There is a demand for almost every class of leather goods which may be purchased for personal use. Leather belting and leather goods of a similar character intended for manufacturing purposes would not, it is said, sell to any extent at present, but most of the articles named above could be sold to advantage. It is important, however, that prices be as low as possible, consistent with good workmanship and fair quality. As the *per capita* wealth in China is low, it is difficult as a rule to obtain high prices for any class of goods. The prices of foreign competitors must, therefore, be met as far as possible in order to obtain a share of the trade. Shoes should be made to sell in China for from 10*s*. 6*d*. to 12*s*. 6*d*. Pointed toes are preferred to the broad rounding toes. The demand would be chiefly for men's sizes. Both brown and black shoes enjoy a ready sale. The former, however, are generally preferred.

DECLINE OF SERICULTURE IN ITALY.

The result of an inquiry, made by the Consiglio per gli Interessi Serici, as to the causes of the decline of silkworm-rearing in Italy, has just been made public. According to this report, this decline may be attributed to four general causes, viz., (1) Emigration of the rural population and consequent increase in the cost of labour; (2) Low prices realised by sale of cocoons due to depression of the silk trade generally throughout Italy; (3) Japanese competition in the supply of raw silk in the world's markets; (4) Increasing production of artificial silk.

To these four chief causes must be added the ravages of the *diapsis pentagona*, which disease has been particularly felt in Piedmont, Lombardy, and Liguria. In the first-named region the extension of the rice fields has gradually reduced the area formerly occupied by mulberry trees. In Emilia, especially in the Provinces of Forli, Parma, Piacenza, and Ravenna, the cultivation of the vine, sugar beet, tomato and market-garden produce is gradually displacing that of the mulberry.

In Tuscany, where the destruction caused by the *diapsis* has been comparatively insignificant, vineyards and intensive culture of all kinds of vegetables are increasing. Here, as in the Marches and Umbria, the want of well-organised markets for the sale of the cocoons is felt, and in consequence the peasantry, finding but little encouragement for their labours, have nearly abandoned the cultivation of the mulberry.

Similar causes appear to exist in the neighbourhood of Rome, the Abruzzi and the Campagna, where the scarcity and the high price of labour is making itself felt. In the last-named region, the mulberry plantations are giving way to the more profitable cultivation of fruit. Diseases of the silkworm have done much to discourage the rearing of the insect.

Further south, in the Basilicata, Apulia, and Calabria, where sericulture flourished in ancient times, it is now found more profitable to cultivate the vines. In the islands of Sicily and Sardinia, the latter once the home of a very flourishing silk-producing industry, as well as for the production of "seed" (silkworms' eggs), the same conditions prevail, and the rural population find little inducement to persevere in the rearing of the silkworm.

Many reforms no doubt are needed, amongst them a more rational cultivation of the mulberry tree. Practical instruction in silkworm rearing, the choice of suitable breeds of the insect, and, above all, the establishment of well-organised markets for the sale of the cocoons when produced is especially needed in order to give an impetus to sericulture throughout the kingdom.

ARTS AND CRAFTS.

Design at the British Industries Fair.—The British Industries Fair at the Agricultural Hall has been both criticised and appreciated to a very considerable extent, but it certainly was a very interesting show, and its importance was materially enhanced by the smaller exhibitions of foreign goods organised by the Board of Trade earlier in the year. The industries

represented were not so numerous as one might perhaps have anticipated, but the exhibits in those trades which were included reached good numbers. The manufactured goods were divided into five departments—printing and stationery: cutlery, silver, electro-plate, jewellery and clocks; china, earthenware and glass; fancy goods, and, finally, toys and games. But in addition to these there was a special section devoted to designs. These were all for surface decoration, and comprised working drawings for cotton printing, tapestry, wall-paper, silk, velvet, lace, printed linen, as well as book covers and posters, and, in some cases, the actual manufactured goods. It must be admitted at the outset that the colour of these exhibits was not all that could have been desired. Very often it was decidedly dull and dumb and drab. Allowances must, however, be made for the fact that the light in which they were shown did not by any means help them. For all that, the collection left one with the impression that in the colouring of our designs we had something to learn from our rivals. With regard to the actual construction of the patterns themselves, we have far better reason to congratulate ourselves. In the various recent exhibitions we have seen that the Austrians at least have been producing simple, fresh patterns for printed linens, cottons and other fabrics, from which, though we may disapprove of some of them, we have a good deal to learn. The designs at the Agricultural Hall demonstrated that in the design of dignified and important work we are by no means behind—at present, though even here there is room for a word of warning. The best pattern design at Islington was not by young men. There were good examples of the skill of masters like Walter Crane and Lewis F. Day, who have passed away; there was excellent work which over and over again stood out from its surroundings by Mr. S. G. Mawson, as well as very workmanlike productions from many other designers, but they were men by no means in their first youth. This may be due to denseness on the part of manufacturers who have not the pluck to employ untried talent. It is probably, in some measure at least, the result of that side of the Arts and Crafts movement which has discouraged our cleverest younger men from turning their attention to design for manufacture.

The poster designs again, though they were not very numerous, made one realise that the great superiority of the Germans' work is not really in their actual designs for posters, but in their grasp of what can be cheaply and effectively done by lithography. Amongst successful designs shown may be instanced Mr. Macdonald Gill's very satisfactory underground railway advertisement and some very direct examples of Mr. George E. Kruger's drawing, as well as a clever sketch by Mr. Walter Bayes. On the whole, the exhibits, though one would like to have seen a greater number of them, formed a very creditable collection. It was in no sense showy, but it revealed the fact that a solid amount of work is being turned out which is both practical and of some real artistic merit. That may not be, and in fact is not, all that could be desired, but it is a great deal better than some croakers would have us believe.

Arts and Crafts at the British Industries Fair.—In the various other sections of the exhibition there was a good deal which was interesting from the artistic side. The pottery exhibits were on a large scale, and included ware of all kinds, and though some of the best firms were unrepresented there was plenty that was worth looking at. Among the more definitely artistic productions exhibited, Messrs. Josiah Wedgwood & Sons' painted lustre was well worth attention, both as beautiful in itself and as a comparatively new venture on the part of an old firm. The lustre effect combined with a matt surface shown by Moorcroft, of Burslem, was new and very happy, as were some of the colour effects in broken glazes obtained by the same firm and the crystalline and flambé work sent by Messrs. Doulton, of Lambeth. Some of the peasant pottery was unnecessarily rude and roughly made, suggesting a rather affected rusticity, but the art pottery of Baron, of Barnstaple, reached a level which brought it into a rather different category. It is to be regretted that there was not a better show of tiles. The industry is an important one, and was very inadequately represented.

As might have been expected, there was some very good work shown in the printing and stationery section; but after the Printing Trades Exhibition last year, which was, of course, on a larger scale and made more special appeal to a technically-educated public, there was little to call for special notice. It was interesting to see, however, that though our tin and paper boxes lagged behind the foreign productions shown at Goldsmiths' Hall in freshness of design, there was nothing to indicate any reason why, with a little care and thought, we should not produce something better still in the near future. The work of this kind was undoubtedly effective in the distance; it was only at comparatively close quarters that one realised how much better it would often have been if only it had been simpler and more direct. The cutlery and silver department and the show of fancy articles hardly claimed attention from the point of view of Art. When we turn to the toy section, however, the case is quite different. Some of the industries included under this heading were, of course, old-established and obviously slow-going; others were so new that they were quite evidently still in the experimental stage; but, taking the exhibits as a whole, there was distinct evidence of a revival

in an artistic direction. The large hand-carved wooden horses, lions, etc., shown by Messrs. Hart & Ventura, simple as they were, were artistically designed, the soft toys exhibited by the Royal Tunbridge Wells Toy Industry, the small wooden things made by the Altrincham toy industry and the cleverly-jointed dragons and other beasts from the East London toy factory, as well as some of the objects shown by the Women's Emergency Corps, all held promise of future achievement. On somewhat different lines the wooden toys exhibited by Messrs. C. Hedges & Co., and by Mr. Arthur Owen, of Sheffield, were well worth attention. Not only did the Noah's arks and the animals inside them show great improvement on the old-fashioned versions, but the wooden soldiers and forts sent by these and other firms had some quite well-founded pretensions to artistic value which were altogether lacking in most of the toys being put upon the market before the war. A few of the rather spooky toys which made their appearance early in the autumn are still to be seen, but the proportion they bear to the whole output does not appear to be very great. It really looks as though there were a reasonable chance of the toys of the future having an artistic quality—most useful in assisting the unconscious education of the child—which, in the case of those which used to be produced, was conspicuous by its absence.

The Design and Industries Association.—The inaugural meeting of the Design and Industries Association held at the Abercorn Rooms, on May 19th, was very well attended. Lord Aberconway was in the chair, and the speakers included Sir Cecil Smith, Mr. John Marshall (of Marshall & Snelgrove), Mr. Sixby (a manufacturer), Professor Lethaby, Mr. Morley Fletcher (principal of the Edinburgh School of Art), and Mr. Caterson Smith (head of Birmingham School of Art). Amongst the most practically interesting and effective speeches may be mentioned those by Mr. Symonds (representing the Board of Trade), who emphasised the fact that, in looking towards the future, we should all have to take into account that our appeal would have to be made to a public whose spending powers were decreased by the war taxation and other causes; by Mr. John Marshall, who strongly urged co-operation between all those concerned, and Mr. Morley Fletcher, who frankly stated his conversion to a belief that trade and art needed to be brought into close contact, and that our business was to accept machine production and do the best we could with it. Mr. Jackson's little speech, too, on the relation between the artist and the practical needs of lithographic printing, was admirably to the point. Many prominent artists, art workers and art masters were in the body of the room and a few manufacturers, though one could have wished that these last had put in an appearance in somewhat larger numbers.

The new association will be watched with a very keen interest by many people. Its foundation is a sign that the younger artists, whose bent is towards applied art, are at length prepared to accept the machine as an ally instead of regarding it from afar as an alien enemy. It is to be hoped that they will succeed in attaching to themselves a sufficient number of manufacturers and distributors of the right type to make the undertaking a real success. The meeting showed that some members of both these classes are anxious to co-operate, as are also some prominent business men—Sir Kenneth Anderson among them. If the Association can only make a start on thoroughly sound lines, there seems no reason why it should not have a long and prosperous career before it. Its chief difficulties will, of course, have to be faced in the near future. If it proves itself strong enough to weather them, it may be of incalculable use to artists, distributors, manufacturers and the general public.

CORRESPONDENCE.

INDIAN TRADE AND THE WAR.

With regard to Sir Charles Armstrong's recent paper on "Indian Trade and the War" much might be said on the seriousness of the rise in freights caused by the war, and on the tendency of this rise in freights to strangle the industries which provide some of the materials that are necessary for the manufacture of munitions of war—munitions on which our very existence as an Empire at this moment depends. Manganese, for instance, which is indispensable in the manufacture of steel, cannot be exported from India to America except on a special permit, for fear lest it may—in its association with steel—find its way to the enemy. Again, magnesite may or may not be contraband. The India Office has but little information on the subject; thus exporters would, on this question, be in the hands of the Collector of Customs at the port of shipment, which would prevent the pre-arrangement of any business between India and a neutral country.

If magnesite is exported in its caustic state, it is probably intended—in combination with magnesium chloride—to be mixed with some other ingredient and used for floorings, in which case it might not be considered necessary to treat it as contraband of war. In a dead-burnt condition, however, magnesite is used for the manufacture of firebricks and as a lining for basic furnaces employed in the manufacture of steel, when its export to a neutral country might be prohibited. But, as the Collector of Customs is not likely to be an expert in minerals, it is not possible to anticipate his views.

Something might also be said respecting the granting of facilities of export to the United Kingdom of all materials necessary for munitions. Sir Charles Armstrong mentioned that the Government of India has taken over the temporary control of the export of wheat. It would be of great interest to know whether the Government is likely to give increased facilities for the export of manganese and magnesite, for the trade in these minerals is being largely suppressed by the excessive freights which at present prevail. It is possible that the stock of manganese in the United Kingdom may suffice for immediate requirements. But the stock of crude and dead-burnt magnesite is notoriously low, and as the speedy and continuous output of munitions of war is a matter of life and death, a consideration of the mineral resources of India has become a question of pressing importance

C. H. B. Burlton.

OBITUARY.

Sir Charles Haukes Todd Crosthwaite, K.C.S.I.—The death of Sir Charles Crosthwaite took place on May 28th at his residence, Long Acre, Shamley Green, Surrey. He was born in Ireland in 1835, and educated at Merchant Taylors' School and St. John's College, Oxford, of which he was an honorary fellow. He then passed into the Indian Civil Service, and proceeded to the North-West Provinces. In 1877 he was transferred to the Central Provinces as Commissioner of two divisions, and afterwards he became Judicial Commissioner there and an additional member of the Viceregal Legislature. In 1883 he was sent to Burma to act for the late Sir Charles Bernard as Chief Commissioner; a year or two later he returned to the Central Provinces in the corresponding post, and two years afterwards he was made a member of the Public Service Commission.

In 1887 he returned to Burma as Chief Commissioner, a post which he held till 1890, and here he did some excellent work. He replaced the costly military garrisons by military police, and established a network of posts, by which the gangs of dacoits and other disorderly and dangerous people were broken up. Before he left the country, in 1890, it was practically settled and pacified, and for his services in this direction Sir Charles received the honour of K.C.S.I.

In 1890 he was recalled to this country to serve as Home member of the Government of India, but he went out again soon afterwards as Lieutenant-Governor of the United Provinces. Through ill-health he came back to England in 1895, and he was then called by Sir Henry Fowler to serve as member of the Secretary of State's Council, in which capacity he continued till 1905.

Sir Charles Crosthwaite joined the Royal Society of Arts in 1893. He was a member of the Indian Section Committee since 1896, and took great interest in the work of the Section. Several times he occupied the chair at its meetings, and he frequently took part in the discussions.

Jonathan James Harris.—Mr. Jonathan James Harris, of Grey Abbey, Cockermouth, died on May 22nd. He was born in 1841, and educated at a Friends' private school at Alderley Edge, Cheshire. In 1883, upon the death of his uncle, Mr. Joseph Harris, he took over his business, retaining the style of the firm as J. Harris and Sons, the well-known specialists in flax embroidery threads. In 1893, for family reasons, the firm was converted into a private liability company, Mr. Harris becoming chairman and managing director, positions which he retained to the end of his life, although for several years failing health prevented his attendance at the mills.

Apart from his business activities, Mr. Harris took a keen interest in politics, and did a great deal of work for the Liberal party in Cockermouth. He was also an archæologist, and a member of the Cumberland and Westmorland Archæological Society. He joined the Royal Society of Arts in 1900.

GENERAL NOTES.

Optical Glass.—Speaking in the House of Commons on May 19th, Sir Philip Magnus, M.P., made some suggestions—first, as to the means of increasing the immediate supply of optical glass, of which there is a serious lack, and secondly, as to the steps which might be taken to retain this branch of industry in our hands when the war is over. He suggested that the manufacturers of instruments should be brought into very close association with the makers of the glass, and he thought it might be practicable for the Board of Trade to appoint an officer who should visit the works of those engaged in the making of optical instruments, and ascertain from them what glass they particularly require, and what glass they may have in excess of their requirements. Some arrangement might be made among the makers of optical instruments, by which an exchange of optical glass might be effected so that the production of instruments might be accelerated. Further than that, the officer should be able to report at once to Messrs. Chance, of Birmingham, who have been very active in supplying the wants of the Navy and Army, and inform them, after having visited these factories, of the particular kind of glass which is urgently needed. Further, the War Office and the Admiralty should give orders only to those houses which are capable with the least delay of producing the instruments that are immediately required. With regard to the second point, he proposed that it might be made an essential condition of any Government contract for the supply of optical instruments for the Admiralty or the War Office that every part of the instruments should have been made in this country; and in conclusion he urged that

further encouragement should be given to the study of applied optics—hitherto almost a German monopoly—which is already being carried on at the Northampton Institute, Clerkenwell, the National Physical Laboratory, Teddington, and the Imperial College of Science and Technology.

A Whistler Exhibition.—An important exhibition of Whistler's works is being held at the galleries of Messrs. Colnaghi and Obachs, 144–146, New Bond Street. The display consists of pictures in oil, pastels and drawings, and should prove of exceptional interest, as it is the first exhibition to be opened since the "Memorial" of 1905. Thanks to the generosity of the collector, the proceeds are to be given to the Professional Classes War Relief Council.

Coconut Cake as Cattle Food. — From the results of the numerous feeding trials referred to in the *Bulletin* of the Imperial Institute, the following conclusions may be drawn: (1) Coconut cake forms an excellent feeding-stuff for milch cows, when fed at the rate of 4½ to 5 lbs. per head per day. It tends to produce a firm butter, and is thus especially well suited for feeding during warm weather, and to counteract the effect of feeding-stuffs which tend to give a soft butter. The results, so far as its effect on the milk yield is concerned, appear to be inconclusive, and further trials to elucidate this point are necessary. (2) The cake may be safely fed to fattening cattle at the rate of about 4 lbs. per head per day, without detriment to the animal or the quality of the meat. (3) The meal is suitable as a food for pigs, but owing to its relatively high price compared with meals usually used for pig feeding, it is doubtful whether it could be employed profitably for this purpose. (4) With regard to the feeding value of coconut meal for horses, it has been shown that it can replace an equal weight of oats in a ration without adversely affecting the animal. When all the factors are taken into account, coconut cake is cheaper than linseed or cottonseed cakes at the rates prevailing recently, and the difference in price per food unit per ton represents a considerable advantage to the farmer who uses coconut cake in preference to linseed and undecorticated cottonseed cakes.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 7...Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Dr. T. G. Pinches, "The Old and New Versions of the Babylonian Creation and Flood Stories."

Royal Institution, Albemarle-street. W., 3 p.m. Mr. W. Ward, "Method of Presenting Character in Biography and Fiction." (Lecture II.) 5 p.m. General Monthly Meeting.

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. J. B. Hobsbaum, "A new process for the refining of Chile Saltpetre." 2. Mr. A. Philip, "A Method of testing Mineral Lubricating Oils for use in forced lubricating systems for Steam Turbines." 3. Major Ferriz, "The Application of Adobe as a material for the construction of Buildings for the manufacturing and storing of explosives."

Tuesday, June 8...Royal Institution, Albemarle-street, W., 3 p.m. Professor J. O. Arnold, "The Evolution of Steel—Influence on Civilisation." (Lecture II.)

Zoological Society, Regent's Park, N.W., 5 p.m. 1. Mr. G. Jennison, "Notes on a nest-making Chimpanzee." 2. Mr. R. I. Pocock, "On the Feet and Glands and other External Characters of the Paradoxurine Genera *Paradoxurus*, *Arctictis*, *Arctogalidia*, and *Nandinia*." 3. Dr. A. Smith Woodward, "On the Skull of an Extinct Carnivore related to *Æluropus*, from a cavern in the Ruby Mines, Mogok, Burma." 4. Miss K. M. Parker, "The Early Development of the Heart and Anterior Vessels in Marsupials, with special reference to *Perameles*." 5. Dr. R. Broom, "On the Triassic Stegocephalians, *Brachyops*, *Bothriceps*, and *Lydekkerina*, gen. nov."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Hon. Sir John McCall, "The Outlook for National Unity."

Wednesday, June 9...Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Rev. W. T. Pilter, "The Personal Names Abram and Abraham."

Geological Society, Burlington House, W., 8 p.m. Messrs. R. H. Rastall and W. H. Wilcockson, "The Accessory Minerals of the Granitic Rocks of the English Lake District."

Japan Society, 20, Hanover-square, W., 8.30 p.m. Mr. C. J. Purnell, "William Adams and his Unpublished Log-Book."

Thursday, June 10...National Pension Fund for Nurses, at the Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Historical Society, 22, Russell-square, W.C., 8.30 p.m. Mr. E. Barker, "The Expansion of Germany since 1890."

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. T. B. Vinycomb, "Note on the Achromatism of a pair of separated Lenses." 2. Mr. W. Salt, "Optical Accessories." 3. Mr. J. H. Sutcliffe, "Trial Frame Manipulation."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. Ward, "Method of Presenting Character in Biography and Fiction." (Lecture III.)

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Annual General Meeting.

Friday, June 11...Royal Institution, Albemarle-street, W., 9 p.m. Dr. H. W. Davies, "Music and Poetry."

Sanitary Institute, Guildhall, Bristol, 11 a.m. Dr. D. S. Davies, "The Co-ordination of Military and Civil Sanitary Services in War Time."

Astronomical Society, Burlington House, W., 5 p.m.

Physical Society, Imperial College of Science, South Kensington, S.W., 8 p.m.

Saturday, June 12...Royal Institution, Albemarle-street, W., 3 p.m. Professor R. S. Rait, "Mary, Queen of Scots. Lecture III.—Mary Stuart and her Son."

Journal of the Royal Society of Arts.

No. 3,264. VOL. LXIII.

FRIDAY, JUNE 11, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

EXAMINATIONS.

The results of the Elementary Examinations (Stage I.), held in March, were sent to the centres on the 1st inst. The results of all three stages in the March Examination have now been issued.

In the Advanced Stage 1,397 papers were worked. Of these 225 were awarded first class certificates, 683 second class, and 489 failed.

In the Intermediate Stage (in which is included Harmony and Rudiments of Music) 4,043 papers were worked. Of these 828 were awarded first class certificates, and 2,029 second class; 139 Higher, Intermediate, and Elementary certificates were awarded in Harmony and Rudiments of Music, and 1,047 failed.

In the Elementary Stage 8,080 papers were worked. 5,386 of these passed, and 2,694 failed.

In the May Examinations 16,004 papers were worked in all. These are now in the hands of the Examiners, and the results will be issued as soon as possible. The Advanced (Stage III.) results will probably be sent to the various centres about the end of June.

EMERALDS: THEIR MODE OF OCCURRENCE AND METHODS OF MINING AND EXTRACTION IN COLOMBIA.*

By Charles Olden.

With the exception of those occurring in the Republic of Colombia, there are no known deposits of emeralds in South America, notwithstanding statements to the contrary. It is quite true that Spaniards in ancient times appropriated stones from private owners in Peru, Ecuador, Bolivia, and as far north as Mexico; but, despite much searching in those countries, no emeralds have been found *in situ*. All must have come originally from Colombia, as they do to-day.

In Colombia there are several deposits. The chief is that now known as the Muzo and Cosquez Mines. There are also those known as the Somondoco Mines, and others of less importance. Most, if not all, of the emeralds in the Republic are found in the Department of Boyacá.

The Muzo and Cosquez Mines are situated 5° 30′ N. and 74° 30′ W. of Greenwich, and about ninety miles N.N.W. of Bogotá, the capital.

The Somondoco Mines are approximately thirty to thirty-five miles east of Bogotá.

Between these two deposits emeralds have been found, both as single gems and as deposits; but they have not, as yet, proved to be of first-class quality.

Historical.—The Spaniards first knew definitely that emeralds were to be had in Colombia on March 3rd, 1537, when the Boyacá Indians gave them presents of this gem as peace offerings. It is said that they also pointed out the location of certain mines, thought to have been what are now known as the Somondoco deposits. The Spaniards, however, did not find gems of such fine quality as they expected, though they continued to work the mines for years. They therefore sought for emerald occurrences in other directions also, and finally located a deposit at Muzo, within a league and a half of the ancient Indian capital of Itoco. The Spanish leader, Luiz Lanchero, established a strong military station there in 1555, changing the name to Santissima Trinidad de los Muzos, and from this position he was able to carry on military operations directed against the Muzo Indians, who were making a stubborn defence of their rights to the emerald mines. Several companies of Spanish soldiers, acting as escort to miners, were successively annihilated, and it was not until 1558 that the first systematic mining work was able to be taken in hand. For a time operations were confined to the Cosquez Mine. Here, however, the Spaniards were so seriously harassed by the warlike and powerful Muzos that, after a few years, they withdrew from Cosquez, and the precise locality of the deposits was lost, both sides having withdrawn from the seat of strife. Recently,

* Reprinted from the *Transactions* of the Institution of Mining and Metallurgy, by permission of the Council.

however, the mines have been re-located within very narrow limits, and will be reopened. They are said to have produced the finest emeralds in the country, and will doubtless give a good account of themselves again.

In 1594 the Spaniards concentrated their attention on the Muzo Mines, recruiting labour from their old enemies, the Muzo Indians. Hardships, sickness and heavy mortality among the male inhabitants of the department, due to forced labour in the mines, practically exhausted the supply of miners. Added to this, the Indian women refused to replenish the stock of males, fearing for them a similar fate, and this, together with the outbreak of a serious fire in the middle of the eighteenth century, caused the mines to be abandoned for a time. The deposits were worked subsequently at intervals by the Spaniards down to the Declaration of Independence of the Republic, when they became the inalienable property of the Government. Since 1844 the mines have been worked under lease from the Government, often in partnership with the lessee, and in recent years always in that way. Short-term leases only were granted until two years ago, when the mines were leased for a period of twenty years to an English company working in partnership with the Government.

Geographical.—Situated on a spur of the eastern Cordillera of the Andes, the Muzo emerald deposits lie in a natural valley somewhat resembling a funnel in shape. They lie from 20 to 150 metres above the valley, and the establishment stands about half-way between those extremes, the slopes on both sides being steep, almost to perpendicular in places.

Mining operations are carried on at various points simultaneously, at altitudes ranging from 3,000 ft. to 4,000 ft. above sea-level.

The approaches to the mines from the surrounding country are difficult, and transport is rendered tedious by reason of the bad state in which the roads are allowed to remain. Mules are employed for transportation of stores and supplies. The time required to reach rail-head varies from two and a half days to three days, according to the state of the roads. From rail-head to the capital is a matter of a few hours.

Climate.—From the fact that the mines lie in a natural *cul de sac*, the climatic conditions are not of the very best, though, generally speaking, Muzo is not unhealthy. It is hot and oppressive in the valley, but is not unpleasant in the neighbourhood of the mines, at the higher elevations.

Labour.—All the native workers are pure Indians, indigenous to the locality. The men are not recruited from the immediate neighbourhood, but are drawn from districts at least a day's journey away from the mines. It is considered more conducive to continuity of work to employ men from a distance, and there are other reasons for this arrangement which are obvious. As in all districts dependent upon native labour, the raw recruit has to be trained, and rates of pay are arranged accordingly. The men are, however, to a large extent familiar with the methods of working, so that little time is needed to train the miners in the special work for which they may be intended. The Indians are engaged for terms of not less than three months, and during this time they are not permitted to leave the establishment except by special permission from the management. As there is but one way into the mines it is not difficult to keep track of the men.

Excellent arrangements exist as to housing, feeding, medical attendance, baths, wash-houses, and other benefits for the comfort and well-being of the men. All are fed free, and there is no limit placed upon the rations of fresh meat, vegetables, etc., supplied.

For the accommodation of the small boys who have elected to accompany their elders to the mines, school is provided. Attendance is voluntary, and a fair number are always present from 6 a.m. to 8 a.m., and no deductions are made from the boys' wages for the time spent in school. The privilege is greatly appreciated.

The compound system, as understood in South Africa, does not exist here. The entire mining area constitutes the compound, and there are no side tracks by which the premises can be left.

Geological.—The Muzo emeralds occur in calcite veins traversing black carboniferous limestone, in which are found ammonites and other fossil remains, which fix the age of the deposit as Lower Cretaceous.

The calcite veins run through the limestone in all directions and at all angles. There is no well-defined dip or strike. In some parts of the deposits where, for special reasons, a mass of the formation has been left standing, with clean and perpendicular escarpment, the calcite veins show a more or less horizontal "lie." There is, however, no rule to go upon in describing the "behaviour" of the veins.

They vary in width from a mere streak less than 1 in. wide up to 18 to 24 in.; but these wider veins are not held in favour, as the gems are more frequently found in the small veins. The very best stones are looked for, and often encountered, in veins running below 6 in.

Emeralds are found in pockets in the calcite or as separate crystals. They are found also embedded in the formation, with or without an envelope of calcite matrix.

Associated with the gem are quartz crystals, water-white to green in colour; iron pyrites disseminated throughout the calcite and the formation, sometimes as large well-developed crystals in the form of pentagonal dodecahedra; green gypsum and Parisite—a fluocarbonate of

cerium, named after Paris, who discovered it at Muzo.

The entire formation is covered with earthy matter to a depth ranging from 6 ft. to 30 ft. or more, overgrown with jungle and forest growths. This capping completely hides all traces of the deposits, and prospecting is impossible until it is removed.

Emeralds are sometimes found side by side lying almost parallel, but not necessarily attached to each other. At times they are found completely bedded in the calcite or in the limestone formation. At other times they are attached by one end only to the matrix. A few days prior to the author's visit to the mines, two very fine prisms of emeralds were found side by side, unattached, weighing respectively over 500 and 700 carats. They were of good colour and transparency, and were of considerable value.

Usually the crystals are very much broken as they are laid bare, and are recovered in fragments. This does not imply that they were broken by the tools used to extract them from the matrix, the fractures being probably due to contortion and disturbance since the crystals were placed *in situ*.

Thickness of Deposit.—The deposit ranges in thickness from a few feet only up to 300 ft. Occasionally it is productive below water-level, but this is rare. The dividing line, or bedrock as it is termed, is usually situated above water-level. One wet deposit was being worked during the author's visit, and it was stated that there had not been a similar instance during the previous four years of occupation by that syndicate. Large veins are not considered favourable to the production of good stones.

Where the Emeralds may be found.—After centuries of experience it has been found that the emerald occurs at Muzo only in its calcite or its limestone matrix. It is not found in the overburden nor below bedrock. When the calcite veins reach the dividing line they are cut off absolutely and abruptly. They do not extend down to the next following stratum. Work ceases at the moment bedrock is reached, and no further prospecting is attempted below the line.

A statement often made, and sometimes seen in print, with regard to emeralds needs correcting. It is said that the emerald, when first exposed to the atmosphere, decrepitates, and that it is so fragile that it may be crushed readily between the finger and thumb. There was no evidence at Muzo to confirm this statement. The gem is found very frequently much broken while still lying within the matrix, and in process of handling it falls into its own fragments, especially when not cemented by a thin coating of calcite. The decrepitation of the crystal occurred probably centuries before it was brought into contact with the atmosphere.

The emerald is confined to its proper environment at Muzo. It is not found in alluvium, as in the case of gold, tin or other minerals. This is not to say that there is no possibility of finding the gem in the river sands in the district; indeed, there is a likelihood that it might be so encountered.

The methods which have obtained for so many years render it most probable that emeralds have found their way into the rivers flowing through the districts where the deposits are situated; but in this event they would be of comparatively recent deposition, and not a product of ancient, natural denudation of the rock. Further, the possibility of washing out the gem from the river-beds is guarded against by the absolute negation of any and every application to undertake this kind of prospecting. It may be stated, with very little fear of contradiction, that the Muzo emerald is found only in its natural matrix there, either in the calcite veins or in the formation enclosing those veins, viz., the carboniferous limestone.

Methods of Working the Deposits.—Having stripped the overburden for as large an area as is thought necessary, say, 150 ft. × 50 ft., where it is intended to continue the work on a productive bank, or, in the case of an entirely new and untried section of ground, of an area probably twice as large, some preliminary examination of the newly-cleaned outcrop is undertaken.

The author has been informed by high officials on the spot, and by experienced managers of mines within the limits of the Colombian emerald deposits, that it is quite possible for an experienced man to tell which part of a formation is likely to prove productive by the "feel" of the limestone when walking over it. Where a gritty, scraping effect is experienced on "scuffing," or scraping one's nailed boots, over a portion of the cleaned outcrop, emerald-bearing veins are likely to be encountered. Where the "feel" is smooth and free from the gritty, scratching sensation, the formation is not likely to prove productive. At any rate, this preliminary walk-over is practised, and, according to the man's personal belief in the theory, his subsequent actions are regulated.

There is always a great amount of dead work to be done before the emerald-bearing veins are uncovered, and the usual procedure is to cut into the formation, step-wise, benches or terraces, one row succeeding another as soon as the course is clear. The benches are 30 ins. deep, and the full complement of men on a bank may reach as many as 150 or more, labour being drafted to the spot as soon as there is accommodation for fresh relays. Some idea may be formed of the immense amount of dead work which may be required to be done when the bank happens to be from 50 ft. to over 100 ft. high. Every ton of hard formation has to be

broken down by manual labour, while at the same time the greatest care is needed to see that no gems enclosed in the matrix are thrown away with the waste.

How the Waste is disposed of. — The *débris* falls down the bank and collects at its foot. It is removed in the manner now to be described.*

Situated as high as possible above any new work which may have to be undertaken, there have been built three large tanks, or reservoirs, of masonry, which collect and store surface water conducted to them by ditches suitably arranged. From these tanks conduits are provided which lead to the foot of any bank upon which work is being done. The conduits are further arranged so that the tanks may discharge into them separately or simultaneously. From the foot of the banks the conduits are carried on until a convenient outlet is found into which the contents may be carried. When a heap of waste rock has accumulated to inconvenient proportions at the foot of the bank, a signal is given to the men in charge of one or more of the tanks, and their contents are emptied into the conduits and led to the desired spot, when the accumulated waste is swept away. In dry weather it may require from ten to twelve hours to fill up the tanks, though fifteen minutes only may be sufficient to discharge them, and it will be seen that the work at the banks is likely to be greatly retarded for want of flushing water. In the wet season the time required for filling the tanks is much reduced, and the work on the banks greatly facilitated.

It is obvious that the conduits should be set at a considerable declivity to ensure a sufficient force of water to sweep away the accumulated waste in its path.

The flushing method of getting rid of the waste has the very serious drawback of the possible washing away of pieces of formation containing calcite veins with embedded emeralds, or emeralds attached to the formation, which are more difficult to detect. Every care is exercised by the overseers on the banks to see that no matrix is thrown away which is likely to contain gems; but accidents may, and do, occur, causing losses, which will continue so long as the flushing method is in vogue.

Natives, under supervision, were employed to walk along the conduits below the banks to search for emeralds. At the time of the author's visit this work was attended with marked success; the eight men so employed more than earned their pay by the stones recovered. Such "free" emeralds may, and probably do, find their way into the sand of the river-beds, giving rise to the assertion sometimes made that emeralds are alluvial in origin. The risk of loss is fully appreciated by the management, but until the method of getting rid of the waste is altered, or at least modified, the risk will always remain.

A bank may prove absolutely valueless after months of work upon it. Despite the greatest care in the selection of the locality for starting the work, no one can estimate the probable value of any particular section of a deposit. In this respect emerald-mining differs from most of the other branches of the industry. The lack of conformity exhibited by the calcite veins as to dip, strike or continuity in any one direction deprive the engineer of all ordinary data upon which he could depend in forming a judgment, and the usual element of chance is much increased when dealing with the elusive emerald. There is little risk, however, in cutting down a bank immediately adjacent to a productive mine, as the veins can be followed into the new ground with reasonable prospects of success. Wherever the veins show they are followed, even if this entails cutting down a bank 100 ft. high. Once a productive formation is found it is never left until it is worked out, and this may prove to be the work of years, as frequently happens at Muzo.

Tools used in the Work on the Banks.—The tools used are steel bars about 5 ft. long and weighing 30 lb., and shovels. The bars are forged to a point at one end and made wedge-shaped at the other. In the hands of an experienced Indian the steel bar proves very efficient in breaking down the formation. It has been estimated that each skilled miner can break down, in a ten hours' shift, 15 ft. × 2½ ft. × 2½ ft., or 93·75 cubic ft., of hard formation, using the bar alone. Explosives are used when necessary, and holes are "jumped" with the same tool, and charged with blasting-powder made on the spot.

As the bank deepens and approaches the calcite veins, great care is exercised to prevent undue force being used in wielding the bar, owing to the risk of breaking the emeralds which may be in the immediate vicinity. In this careful work the Indians excel, and they can strike repeatedly the same spot in the formation with the pointed end of the bar without deviating one hair's breadth, using just sufficient force to break the limestone without smashing the calcite or the gems which it may contain. An unskilled miner, native or white, could do immense damage when using the bar in the neighbourhood of an emerald-bearing vein.

The pieces of vein liberated, together with the adjacent formation, are carefully examined for emeralds, and are set aside for conveyance to the sorting sheds, where, with proper tools and suitable surroundings, a more critical examination is made.

Emeralds showing in position in the matrix, before detachment, are removed by a "pricker,"

* The methods described here were those in vogue during the tenure of the late syndicate. It is probable that the present company have introduced many improvements.

a tool capable of loosening the gem from its bed or scraping it out of any small cavity in which it may be lying. Great care is exercised in this operation.

At regular intervals, or as often as there is a sufficient accumulation of possible matrix sorted out on the bank, it is conveyed to the sorting sheds to be dealt with in due course.

Cleaning up when Bedrock is reached.—Mining work continues on the banks until bedrock is reached. The last stage here is the careful examination of the "floor" for detached emeralds, and everything is scraped up, swept and washed to ensure that no gems are left behind. The sweepings are collected and carried to washing tables set at a slight angle, over which a steady, well-regulated stream of water is allowed to flow evenly. Here a number of small boys are engaged washing the dirty sweepings and general clean-up from the banks, rejecting the waste and picking out any emeralds which may show. They collect the gems in small pieces of coconut shell and hand them to the overseer, who, it is unnecessary to state, never leaves his place overlooking the tables.

Constant Vigilance exercised.—A bank is never left, day or night, so long as it is productive. Relays of miners are drafted to it to take the place of those who retire to meals, which are served only in the dining-rooms and never at the banks. Other relays of miners are drafted as necessity demands. When a bank becomes more than ordinarily productive, as when a rich pocket is discovered, the number of overseers is augmented and extra vigilance is exercised to prevent theft or carelessness in handling the matrix, and to see that no formation likely to carry gems is thrown over the dump. In this way work continues till dusk, when the banks are put in charge of military police or soldiers, of whom a large force is always stationed on the mines and in the city of Muzo.

Method of Working a Wet Mine.—In working a wet mine the procedure is much the same as with a dry mine, except that the work assumes the form of a trench wide enough to embrace the particular veins which are continuing productive. Greater care is necessary in dealing with the waste and in handling the valuable matrix, owing to the more restricted area of operation and to the greater facility which exists for the misappropriation of the gems. The appearance of the bottom of the trench resembles a miniature coal-mine. Everything is black, and, as a consequence of the mixing of the water with the fines from the carboniferous limestone, well-trodden by the miners, it becomes increasingly difficult to recover all the gems set free. Occasionally they are buried in the black mud, the natural unevenness of the floor increasing the danger of treading-in the crystals.

All waste is carried from the trench in hide bags, and is washed on the tables previously referred to. Loose gems are recovered, the waste thrown away, and the calcite and limestone, suspected of carrying gems, set aside for conveyance to the sorting sheds.

Instances of theft are generally detected, but it is questionable if misappropriation will ever be stamped out completely. Every care is taken in the trenches and elsewhere to minimise it, principally by making the lot of the miners as comfortable and pleasant as possible, thus removing the necessity for pilfering. This procedure on the part of the management has had a decidedly good effect on the men, and theft is much less prevalent than formerly.

In the trenches the same rule obtains as to drafting in relays of miners, and the work is never left until dusk. The water is then allowed to accumulate and to submerge the workings, and remains until the following morning. This procedure renders it difficult, if not impossible, for "poaching" to take place during the night.

According to the quantity of water which has collected in the trench, miners are detailed to pump it out. This is done by means of bamboo pumps of the usual native type. Pumping begins at 3 a.m. and is completed by 6 a.m., when the day's work begins. From two to six men are required to man each pump, depending upon the diameter of the tube and the depth from which the water has to be lifted. Should this be greater than 15 ft. or 16 ft., it is pumped in series.

When bedrock is reached the mine is abandoned, as has already been mentioned, and work commences on the formation immediately adjacent to that just worked out. The same calcite veins are exposed, and, if persistent enough to live through the new bank, are followed into the next adjacent formation, and so on.

The Spaniards worked parts of these mines by tunnels. There are serious objections to this mode of mining, principally the great difficulty experienced in following the small veins in their remarkably circuitous meanderings. After much consideration and centuries of experience, it has been found that open cutting presents many advantages over tunnelling. All operations are carried on in daylight —a matter of the greatest importance when the value of a one-carat stone of first-class quality is considered.

The Treatment of the Emerald-bearing Matrix.—Upon arrival at the sorting-sheds of the establishment, the valuable matrix is dealt with as follows: The larger pieces are broken up by light hammers and the resulting product is again reduced in size. Each piece is examined very closely for gems or emerald colourations and the waste sorted out. The final product is reserved and is again broken by light tools.

The emeralds which have become loosened are picked out, and if clean are placed into stock, while those gems to which matrix still adheres are placed in a bath of cold dilute hydrochloric acid until they are cleaned.

The Grading of the Emeralds.—The emeralds are sorted into a variety of grades, some fifteen in all, according to colour, transparency, size, freedom from fissures or enclosed impurities, and various other considerations, and are then ready for the market.

The Inexhaustibility of the Deposits.—The topography of the deposits, as seen to-day, with its evidences of alteration in contour and general features, lends truth to the legend that the mines have been worked for one thousand years or more. It would seem to be impossible in less time so to have altered the surface of the locality as to have produced its present appearance. The topographical changes now taking place are probably an exact reproduction of what has been going on for the last ten centuries, and the very primitive methods of mining and quarrying in vogue are undoubtedly those handed down by the ancestors of the present-day Indian workers. There is no evidence whatever that the deposits are likely to become exhausted for the next few hundred years.

It is not likely, moreover, that they will be worked to exhaustion in the shortest possible space of time, as the rate of extraction of the precious stone must always be dependent upon the ability of the market to absorb the gems at profitable rates.

In the cutting of a watercourse 8,000 m. long, for the most part through carboniferous limestone, no less than twenty-eight new areas containing calcite-bearing formation were intersected, extending throughout the ditch line, and these new finds will not be exhausted in a day. No stronger evidence of the presence of the emerald than is seen in these exposures was needed by the earliest workers when commencing operations on what subsequently proved to be productive banks, and there is no reason to suppose that these, when attacked in their turn, will give anything but a good account of themselves.

The cutting of ledges, whether for roads or watercourses, along the slopes of hills, in known emerald-bearing districts, constitutes a ready and effective method of prospecting, and it is not at all unlikely that the making of roads by the early Indians led them to discover the green stone which became an object of value, and, subsequently, one of the main causes which led to their own undoing.

BENGAL INDUSTRIES.

A report by Mr. J. A. L. Swan, I.C.S., on his inquiry regarding the industrial development of Bengal, has recently been issued. It is in two parts. Part I. deals in a general way with the present position, the possibilities of the future, and the measures which Government might adopt to encourage the growth of indigenous industries. Part II. consists of notes on the various industries which he has examined. Part I. is as follows :—

Some Existing Industries.

When Mr. Collin made a survey of the industries of Bengal in 1889, he found no joint-stock enterprises working with Indian capital and under Indian management. In 1907–08, when Mr. Cumming and Mr. Gupta made similar inquiries, the Swadeshi movement was at its height, and had roused considerable enthusiasm among the middle classes, who saw in industrial development a new field of employment and less severe competition than in the professions. Companies for the manufacture of pencils, matches and soap, for cotton-weaving, hosiery and tanning were floated. The big capitalists were not generally attracted by these schemes, but considerable sums were subscribed from the savings of the middle classes. Bengali directors were appointed, and in almost every case the management was entrusted to a Bengali. If these enterprises had met with a reasonable measure of success, the industrial development of Bengal would have progressed much more rapidly than it has done, or is likely to do. Unfortunately, from various causes, none of these concerns has so far achieved any success. The majority have ceased to work, but one or two are still struggling for existence. I have examined the history of these concerns, and have discussed the matter with many gentlemen who were actively interested in them.

Why Swadeshi Failed.

Difficulties in obtaining raw material, want of skilled labour, and the lack of banking facilities contributed in some cases to their failure; but the two most important causes were: (1) insufficient capital, and (2) inefficient management.

The promoters of these companies, handicapped by want of experience, failed to appreciate the danger of starting a business with insufficient capital. In almost every case the paid-up capital fell far short of the nominal capital, yet a beginning was made in the hope that money would be more freely subscribed when it was seen that work had actually started. One company, for example, was floated with a capital of Rs. 5,00,000. Of this Rs. 85,000 was subscribed, and only Rs. 65,000 was paid up. Nevertheless, plant was purchased and work commenced. It was at once found necessary to borrow money at a high rate of interest. In the circumstances, it was impossible for the company to make any profit, and naturally no more shares were taken up

by the public. The enterprise was thus hampered from the outset, and has never been able to free itself from the incubus of the debt. Another company was floated with a capital of Rs. 2,00,000, of which about Rs. 91,000 was paid up. Plant was purchased and work started; but it was soon found that the amount available as working capital was wholly insufficient to buy the raw material required to keep the machinery at work.

Want of Capital.

Adequate capital is particularly necessary in the case of industries run by Indian capital and under Indian management, owing to the reluctance of banks and of firms that supply machinery and raw materials to give them credit. When a concern has to pay cash for its raw materials, and at the same time to allow credit to its customers, it must have at its command much more working capital than a similar business which enjoys the usual banking facilities. The absence of these facilities has been mentioned to me as a serious difficulty by almost all the managers of Indian manufacturing concerns.

There are at present no signs that Indian capital is likely in the near future to be freely invested in industrial enterprises. Wealth is not diffused over a great middle class as in England. Apart from the Marwaris, it is mostly in the hands of landowners and a few professional men who prefer to invest their surplus in land or to lend it out. Money lent on mortgage will yield 6 per cent. with absolute security. If the capitalist is willing to take risks, he can get very much more than this. In these circumstances, he is naturally reluctant to invest money in industrial enterprises, the success of which is problematical, and which, at the best, are not likely to yield much more than the 6 per cent. obtainable without risk. His reluctance is enhanced by the discouraging history of these companies. Until it has been demonstrated by individual enterprise or otherwise that new industries can be developed with some assurance of profit, the capital of Bengal is not likely to flow into industrial channels.

Inefficient Management.

It is not a matter for surprise that inefficient management should have largely contributed to the failure of the Swadeshi companies. From the character of the movement, it was natural that they should be started, not only with Bengali capital, but also under Bengali management. There were, however, few men in Bengal who were fitted by training to be directors or managers of industrial concerns. The directors were chiefly selected from the professional classes. Many of them were men of great abilities and eminent in their own professions; but they had had no opportunity of gaining experience in business methods and finance. In industrial countries, the board of directors of a company includes men with an intimate knowledge of its particular business. Such men were not available in Bengal. Consequently the directors of these companies were hampered by the lack of expert knowledge and advice. This led in some cases to serious results. For instance, one company purchased plant which was afterwards found to be useless and which had to be discarded.

It was equally difficult to find men competent to manage those concerns. The field of choice was practically limited to those young men who had been sent in the past few years to Europe, America and Japan for industrial training. Many of them had returned with excellent certificates and a high degree of technical knowledge; but they had had no training in the business side of a manager's duties. Their qualifications would have made them most valuable assistants, and after some years' experience they would probably have been competent to undertake the duties of management; but with no training in how to buy and sell to the best advantage, or how to finance a business, they were not then qualified to organise and manage new industries, and it is not surprising that in most cases they failed.

Some Successes.

While the experiences of these joint-stock companies have been depressing, other more hopeful developments have taken place. There are now a number of industrial concerns, founded by individuals or small syndicates, which are working at a profit, or which have made sufficient progress in the experimental stage to justify confidence in their success. A private individual who enters on such an enterprise generally does so because he has a natural inclination for the business and probably some practical knowledge of it. He knows exactly how much capital is at his command, and he cuts his coat according to his cloth. The shareholders of the limited companies expected an industry to spring fully equipped from the promoters' brain. These practical men, realising that they and their workmen must buy experience, have been content to start on a small scale, and to extend slowly as they felt their way. The earliest enterprise of the kind was the Bengal Chemical and Pharmaceutical Works, which, founded in 1892 by a small syndicate, is now a limited company with a paid-up capital of Rs. 3,50,000 and pays a steady dividend. Messrs. F. N. Gooptu and Co., starting on an experimental scale in 1905, have now a large and well-equipped factory for the manufacture of penholders, nibs and pencils, and hold large contracts from the Controller of Stationery. Messrs. P. N. Dutt and Co., of the Bengal Galvanising Works, turned out five dozen

galvanised buckets a day when they started in 1908. The plant has been gradually improved and extended, and the outturn is now 150 dozen a day. The Calcutta Pottery Works have a thoroughly up-to-date plant, including machines for the manufacture of electrical porcelain fittings. Several small hosiery factories are working successfully, and the Bengal National Tannery is now in a hopeful position. If the success of these and other private ventures is set off against the failure of the joint-stock enterprises, it may fairly be claimed that the last few years have been a period of distinct, if slow, progress in the industrial development of Bengal.

Effects of the War.

When the European war broke out, it appeared that an opportunity had presented itself for a more rapid development of the industries of Bengal. In some cases raw materials are exported from this Province and are manufactured in Europe, and in other cases articles are imported from Europe, though the raw materials are available here. Hides, for example, were exported in enormous quantities to Germany, where they were tanned. Chemicals to a very great value are annually imported from Europe, though there is abundance of raw material for the manufacture of many of them here. It seemed certain that if such articles as chemicals, leather, glassware, matches and pencils were produced locally, they would find a ready market at a profitable price.

But though the war presented opportunities, it also created difficulties. The capitalist, affected by the prevalent feeling of uneasiness and uncertainty, became nervous and anxious to keep the control of his money in his own hands. The effect of the situation on existing industries was not encouraging. The jute trade was, for the first three months at least, in a state of stagnation. The *raiyat* who could not sell his jute was unable to make purchases, and the textile industries lost their great market in Eastern Bengal. One gentleman, who owns a silk factory, told me that at the time of the "pujas," when he generally sells most of his annual outturn, his sales this year were one-thirtieth of the average. Many industries were seriously affected by the cessation of imports of aniline dyes, chemicals and bottles from belligerent countries. Advantage of the situation was taken by some existing firms to develop new lines of business, but no new productive industry has as yet been started.

While the industrial development of the Province must depend on private enterprise, I think that the encouragement of Government might take a more active form than it has hitherto done. One demonstration is more convincing than a dozen monographs. Anyone who has decided to start an industry will find much valuable information and advice in the monographs published by Government, but no one is likely to be persuaded by merely reading a monograph to start an industry. If, on the other hand, Government can demonstrate that an article can be manufactured at a certain cost, that a market can be found at a certain price, and that the margin of profit is reasonable, the opportunity will not be long neglected.

In his despatch of July 29th, 1910, to the Government of India, the Secretary of State expressed his disapproval of "pioneer industries" conducted by Government on a commercial scale, likely to interfere with private enterprise. He considered, however, that there was no objection to the establishment of a bureau of industrial information or to the dissemination of intelligence and advice regarding new industries, processes or appliances. To be of any real value, such information and advice must be based on actual experiments, such as are now being, or are about to be, undertaken in Madras.

The Example of Madras.

The Director of Industries, Madras, is in an advantageous position for making these experiments. He is at the head of an organised department which has been in existence for some fourteen years, and has a large expert staff. He is assisted by an Inspector of Industrial Schools, an officer in charge of pumping and boring operations, a dyeing expert, a leather expert, and a personal assistant, who is an experienced mechanical engineer. The subordinate staff consists of twelve supervisors, twenty-four mechanics, and sixty *mistris*. His annual expenditure amounts to almost three lakhs of rupees, of which about half is absorbed by technical education. Since the war broke out he has been given considerable grants for the purpose of practical experiments, which will include ground-nut-pressing, soap-making, glass-making, and the manufacture of paper-pulp, matches and pencils. The experiments in ground-nut-pressing have been in progress for some time with a small plant worked by an oil-engine. The results have led Government to make a large grant for experiments on an extended scale. These will not compete with private enterprise, as a local firm supplies the raw material, and the oil and oil-cakes produced are returned to them. This firm keeps accounts of the cost of the ground-nuts and of the price obtained for the oil and oil-cakes, while the Director keeps an account of the cost of pressing. In this way he is able to arrive at an accurate estimate of the commercial possibilities of the business. As a subsidiary industry, he proposes to experiment in the manufacture of soap with ground-nut oil.

Some time ago a glass factory was erected in Madras, and was equipped with automatic blowing-machines for making soda-water bottles.

This enterprise failed for causes which, the Director thinks, might have been avoided. The proprietor has placed the buildings and machinery, with the stock of raw materials, at the disposal of the Director. Some alterations are being made in the furnaces, and the machinery is being brought into working order. When this is done, the Director proposes to start the manufacture of soda-water bottles and bangles on an experimental scale. If he is successful, the proprietor, it is hoped, will take up the business again. A pencil-making plant, which was imported at the time of the Swadeshi movement, and a paper-pulp factory have also been lent to the Director by the owners, who had failed to worked them profitably.

Those experiments have not yet reached a stage at which practical results can be expected. The Director can, however, point in the past to his successful work in the field of chrome-leather tanning and the manufacture of aluminium ware. The Madras Aluminium Works have proved a highly profitable enterprise, and the Mysore Tannery, which was established under Mr. Chatterton's auspices, also pays a dividend. The success of the Director's efforts to extend the rice-hulling industry in Madras has been so unexpectedly great that he now fears the effects of too keen competition. I think that these examples are sufficient to justify the hope that similar experiments in other parts of India will lead to practical results. The most suitable industries for such experiments are, in my opinion, those which have already been tried, and have failed for causes which might have been avoided. The officer-in-charge of the work will have these causes before him, and will know exactly what difficulties he must try to overcome. He will also probably be able to obtain the use of existing plant, and so reduce the cost of the experiments. In Bengal, for instance, the manufacture of glassware and matches has been attempted and has failed. The attempts at glass-making were reviewed by Mr. Wagle, the glass expert, in his report written in 1906, and he attributed their failure to preventible causes. It would, I think, be possible to arrange with the proprietor of the glass factory at Sodepur for experiments in glass-making, unless, in the meantime, these are carried out by a European firm which is interesting itself in the matter. I have found two match factories, of which one has ceased to work, and the other is likely to do so in the near future. The failure in both cases is directly due to want of capital. What the result would have been if these concerns had had sufficient capital it is impossible to say. There are one or two other difficulties to be overcome, such as the question of a suitable wood. The *genwa* wood from the Sundarbans, which was used in both factories, was not altogether suitable, as it did not split evenly. I think that this is an industry in which practical experiments, made with the co-operation of the Forest Department, would be of great value.

Government Patronage Needed.

Government patronage might be extended more freely than at present to articles of local manufacture. A partner in a large engineering firm complained to me that they do not get a chance of tendering before indents are sent to the Director-General of Stores. When they get an order it is for a small quantity required to meet an unforeseen demand, or because the amount indented for has proved insufficient. For a small quantity a higher price must be charged than for a large order. This, however, is taken as their fixed price for an article. He gave me a concrete case in which they got a small order for rivets from a Government department, and had to charge Rs. 9 a hundred. When they asked for further orders, they were told that the imported rivets only cost Rs. 7–12 a hundred. On making enquiries, they found that the annual requirements were very large, and that if they got the whole order they could profitably supply them at this price. They represented the position to the officer-in-charge of the department and have now got the order. In another case, I found that certain articles of local manufacture had been brought to the notice of the head of a department by Mr. Cumming in 1908. When the factory asked for an order they received the reply: "Should occasion arise for the purchase of these articles locally, your letter will then be considered." When I brought the position to the notice of the present head of the department personally, he was keenly interested, and will give the factory his orders if his requirements can be met. The fullest opportunity of tendering should be given to local firms before indents are sent to the India Office.

Some Suggestions.

In dealing with particular industries in the second part of this report, I have made some suggestions which may be briefly summarised here :—

1. Co-operative credit societies should be established among cottage-workers, such as cotton-weavers, silk-weavers and brass-workers. The officer-in-charge of these societies should assist in the purchase of raw material and in finding markets for the finished article.

2. Demonstrations in the use of improved processes and appliances should be given at suitable centres. Much has already been done in this direction for cotton-weavers. But demonstrations might also be given in such matters as the use of the flyshuttle for *tussar* and silk-weaving, and the use of an improved lathe and a die-stamping machine for brass-work.

3. The Forest Department should make

special arrangements for the supply of suitable wood, on favourable terms, to such industries as matches, pen and pencil-making.

If such measures as these are taken, the Government, I think, will have gone as far as they can go to encourage the industrial development of the province. The rest must depend on private enterprise, and, for the present, on individual efforts rather than on joint-stock companies. The industrial development of England was already far advanced before the day of joint-stock companies arrived, and, even now, the great manufacturing companies are almost all the outcome of private enterprises which were started on a small scale, and were established successes before the public was asked to subscribe its money. In Bengal, too, individuals must create confidence in their commercial ability and integrity by their success. When they have done so, the capitalist, or the middle-class man with savings, will not be slow to avail himself of a new field of investment.

THE MANUFACTURE OF GASOLINE (PETROL) FROM NATURAL GAS IN THE OIL-FIELDS OF OKLAHOMA.

By Chas. N. Gould.

During the past few years a new industry has been established in the oil-fields of North America, particularly in the Ohio-Pennsylvania fields in the eastern part of the United States, and the Mid-Continent fields of Kansas and Oklahoma. This industry consists of utilisation of a product which has heretofore gone to waste—namely, the so-called "casing-head gas" from the oil wells—in the manufacture of gasoline.

Chemists have long recognised the fact that petroleum and natural gas are but two manifestations of the same series of complex hydrocarbons, petroleum being the liquid form and natural gas the gaseous form. If petroleum is distilled in the retort in the chemist's laboratory, or in the still in the refinery, heat is employed to drive off the lighter and more volatile substances. The first products are given off in the form of gas, which, being condensed, forms various light oils, the most important of which are naphtha, benzine, gasoline (petrol), and kerosene.

It has been found that wells from which oil has been taken for a number of years often yield gasoline in the gaseous form; that is to say, the natural gas given off from these oil wells can be condensed to form gasoline.

Natural gas may be divided into two classes: (1) So-called "dry gas," known and used as a natural gas of commerce, which usually comes from wells containing little or no petroleum; and (2), a gas containing easily liquefiable vapour known as "wet gas," which comes from wells yielding petroleum. The latter product is often known as "casing-head gas," because of the fact that it is most frequently obtained from between the casings or pipe in the oil wells.

As early as 1904 the liquefaction of natural gas products by compression was undertaken in the oil-fields of Pennsylvania and other States in the eastern part of North America. Within the past few years this industry has assumed considerable proportions in the mid-Continent fields of Kansas and Oklahoma. In the year 1914 there were more than sixty separate gasoline plants in Oklahoma engaged in the extraction of gasoline from "casing-head gas." The average amount of gasoline obtained varies from one gallon to seven gallons of the liquid product to each 1,000 cubic feet of gas, the average being, perhaps, three and a half to four gallons per thousand feet. The price paid for the gasoline at the various plants in Oklahoma varies from 5 to 7 cents per gallon.

It has been found by experience that the gasoline obtained by compression is of unusual strength, and at the same time it is extremely volatile and evaporates rapidly, so that in order to utilise the product it is often necessary to blend it with certain other light oils, naphtha being the one usually employed. Gasoline of the gravity of 87 per cent. to 95 per cent. Baumé is mixed with naphtha with a gravity of 50 per cent. Baumé, so that the gravity is reduced to 65 per cent. to 70 per cent. This process renders the liquid more easily handled and produces a high quality motor spirit.

The method of manufacture of natural gas is briefly described in Technical Paper No. 10 of the United States Bureau of Mines as follows:—

"Up to the last two years the general practice in the manufacture of liquid natural gas was to make the product by compression of the gas in single-stage compressors, operated at a pressure of 150 to 300 pounds per square inch. The one product thus obtained, so-called 'natural gasoline,' was run into a tank and 'weathered.' The weathering consisted in allowing the lighter portions to volatilise spontaneously and escape into the open air until such time as the boiling away of the liquid had practically ceased. Thus the process involved a loss of 25 to 50 per cent., or even more. This loss was an absolute waste, not only of power and of cost of operating the engines and compressors, but of the product itself.

"The next step in the industry was to pass the waste gases (of which only the small quantity used for power had been utilised) from the single-stage compressor through a higher stage compressor, thereby getting a second and more volatile product—a 'wilder' liquid—which was run back into the first tank and mixed with the first or heavier condensate. This mixture was then again weathered to a safe degree, whereby it lost the greater part of the more volatile product that had been condensed in the second stage.

"Recently the process has been improved another step, in that the first stage compressor product is run into one tank and handled as ordinary gasoline; the second-stage compressor product is run into a second tank and handled as a lighter gasoline, with which the heavy refinery naphthas can be enriched or enlivened.

"The last-mentioned method of using the second-stage compressor product should receive wide recognition, and a market for the product should develop that would be no mean factor in the industry. Blending in the proportions of, say, one part of the product to four or five parts of the refinery naphthas makes these heavy naphthas more volatile and of greater value as fuel for automobiles; it also greatly increases their general usefulness. The proportions to be used in blending, however, must be determined more definitely by test.

"The natural gas of this country frequently contains light products that do not condense in the second-stage compressor, and for which it is practicable and necessary to instal three, four, and even higher stage compressors. These light products—true gases at ordinary temperatures and pressures—can be compressed and liquefied, but the liquid gases so obtained must be handled as gases and not as oils. The mistake heretofore made in the 'natural gas gasoline' industry, as some have recognised, has been the attempt to handle the light gaseous products as oils and not as gases. Until the manufacturers of this lightest third of fourth-stage compressor product recognise its gaseous nature, the absolute necessity for insuring the safety of the public involves certain restrictions in its transportation, and not until the realisation that this extremely volatile liquid should be handled only in strong steel containers capable of withstanding high pressures, will it be transported with safety."

HOME COLONISATION IN JAPAN.

The *Monthly Bulletin of Economic and Social Intelligence* contains an interesting article upon home colonisation in Japan, which is here summarised briefly.

The writer has considered it convenient for his purpose to divide the territory of the Empire into three parts and to examine the question separately for each part. The territory is divided thus: (1) Japan Proper; (2) Hokkaido (Yezo) and Sakhaline; (3) Korea.

(1) *Japan Proper.*—The characteristic features of this division of the Empire are farm lands worked from remote antiquity, a dense population, and landed property very much subdivided. Home colonisation tends to the formation of holdings of medium size, not by the transformation of large estates (of which there are scarcely any), but by the union of scattered parcels belonging to the same owner and the utilisation of the boundary land between one parcel and another. Home colonisation, therefore, in this part of the Empire is essentially farm land readjustment.

After dealing briefly with the history of rights in rural property in Japan, and outlining the actual economic situation of the proprietors and the present development of agriculture in Japan proper, the writer turns his attention to the question of the amount of cultivable land, and presents the following figures: Land under cultivation, 5,223,000 chô (1 chô being equal to 0·99 of a hectare); grazing grounds and uncultivated land, 1,868,000 chô. In Japan proper, that is to say, only 73 per cent. of the area adapted to cultivation is, in fact, cultivated, while 27 per cent. still remains to be brought under cultivation. Home colonisation in this territory has for its principal objects: (1) The readjustment of holdings of land already cultivated; (2) the utilisation of land at present uncultivated. With respect to the process of readjustment (or "restriping" as it is sometimes called) we shall content ourselves with reproducing some of the figures presented in the article in the *Bulletin.*

During the year ending August 31st, 1913, the number of new parcels of land dealt with under the law relating to readjustment was 765, representing a total area of 36,501 chô. The total number dealt with since 1900 is 5,503, with a total area of 320,451 chô. In these figures are included 171 parcels of land with respect to which the work of readjustment has been completed and the respective societies occupied with the operations have been dissolved.

The total number of individuals undertaking farm land readjustment and of members of associations for that purpose and for the reclamation of waste land reaches the somewhat high figure of 522,316. As regards the progress of the work, the position on August 31st, 1913, was as follows.

A report for the period ending August 31st, 1912, showed that only for 8·3 per cent. of the parcels (12·3 per cent. of the area) had the work been commenced. At the present time the work is being carried out on 42·8 per cent. of the parcels (59·4 per cent. of the area), and has been terminated on about 48·9 per cent. of the parcels in connection with which it had been begun. The total area readjusted is, however, only 26·3 per cent. of that of the parcels in question. The following figures, among others, are presented in the article in question, with respect to the work of reclamation of waste lands. According to recent inquiries carried out by order of the Department of Agriculture and Commerce at Tokyo, the area shortly to be reclaimed is about 72,000 chô to be transformed into rice fields, and 306,000 chô to be converted into fields temporarily irrigated, altogether 378,000 chô of new land, now uncultivated or covered with forest, belonging partly to the

State and partly to private owners. In addition, during the year 1912, 91,684 forest lots of a total area of 15,600 chô were dealt with. Of this area 10,955 chô were adapted to the cultivation of permanent crops, 3,678 chô to rotation crops, and the remainder were utilised for the erection of dwelling-houses and for various other purposes—*e.g.*, for cemeteries, for the erection of temples, etc.

Hokkaido.—This part of the territory of the Empire is very thinly populated, and the land is either not cultivated or cultivated in a very primitive manner. Home colonisation here has for its object the formation of small and medium-sized holdings, and this object it is sought to achieve by encouraging immigration and by conceding land for purposes of reclamation. It is in this part of the Empire that the work of home colonisation is proceeding with greatest activity, and at the same time most nearly resembles, in its methods and objects, the process of home colonisation as the term is usually understood in European countries.

The history of the work may be divided into three periods—namely, the period of feudal dominion; the period of the Colonial Department (*Kaitakushi*); and the period of the Government of Hokkaido (*Hokkaido-chô*). The work carried out by the *Kaitakushi* or Colonial Department is of outstanding importance, and may be divided into: (1) Measures for obtaining the labourers necessary for agriculture, such as free grants of food supplies, implements, or money to immigrants, concessions of land, etc.; (2) measures for the reclamation and improvement of the land through exemption from taxation, special facilities for buying, etc.; (3) prizes and rewards.

With respect to the results obtained, it will be sufficient to note that, during 1912, the number of immigrants into this district was 61,156, as against 13,963 emigrants, giving thus a net increase of population of 47,193.

It will be seen that the number of people who leave Hokkaido each year to return to Japan proper is still very considerable. This is due to many causes, not the least important of which is the comparative severity of the climate to which the Japanese cannot always adapt themselves, especially those Japanese from the Southern provinces accustomed to mild and temperate and even warm climates.

From another part of the article which is here summarised we learn that in this region small holdings are most numerous, while, on the other hand, large holdings cover most of the area. But under the special economic conditions of agriculture in this region, even farms of more than 50 hectares may be considered large, and thus large holdings assume an even greater importance. This leads to the inconvenience of the lease of farms by large proprietors to small farmers.

While in 1886, in fact, farms worked by the owners represented 82 per cent. of the total number of farms, in 1912 the proportion had fallen to 43 per cent.

Korea.—Land in Korea also is cultivated only partially or imperfectly; the population is sparse; the supply of water is badly utilised; and, while large areas have been denuded of timber, there are still extensive forests. Colonisation is limited almost exclusively to reclamation work without any special attempt to create small or medium-sized farms; and important work for the better utilisation of the water supply is being carried out.

The encouragement of emigration from the mother country is also characteristic of the work of colonisation in Korea, the Japanese Government being anxious to establish as large a number of colonists as possible in the newly-acquired territory.

INDIAN TOBACCO.

A Bulletin just issued by the Agricultural Research Institute, at Pusa, by Mr. and Mrs. Howard, who have done much valuable economic botanical work in India, recalls the strides that in recent years have been made in the improvement of tobacco cultivation in India, particularly in Bihar. There are none in India now who remember the Chinsurah cheroot, the manufacture of which, apparently, languished after the Dutch disappeared from India; but if it was made from the crude Indian tobacco, it could not have been a very delectable weed. There may be some, though, who remember the attempt of a Calcutta firm who, about thirty years ago, tried to introduce at Pusa the manufacture of pipe tobacco from indigenous leaf. The best that can be said of the result is that, as a smoke, it left much to be desired, and attempts to popularise it in Calcutta failed. Since then we have heard of more than one attempt to grow and cure a tobacco in India, both in Bihar and South India, that will take the place of the American tobacco that forms so large a part of the cigarette and pipe tobacco imported into this country. . . . In 1910 or thereabouts several of the tobacco factories came into existence, and cigarettes made from Indian tobacco began to find their way into the market. The best known of these is the Peninsular Tobacco Co., with factories at Monghyr, Bangalore, and other places. Having the huge and wealthy Trust, the Imperial Tobacco Co., behind it, the Peninsular Tobacco Co. has been able not only to undertake the manufacture of cigarettes on a gigantic scale, but to experiment on its own account and to co-operate with the Department of Agriculture in trying to secure a tobacco of fixed and uniform grade suitable for the making of cigarettes. The Bulletin under notice, and a previous one by

the same authors, are largely an account of these experiments. After many discouragements and in the midst of many difficulties of cultivation and curing, it has been possible to secure what was desired. A type of Indian leaf has been discovered which has the light colour, the fine texture, and the necessary elasticity when cut to make good fillings for cigarettes, and the flavour and aroma are said to be fair. In making these experiments imported varieties of American tobacco did not, under the altered conditions, reproduce the qualities desired, and the Indian varieties gave more promising results. The main reason for this was that the American varieties were not quick growers, an imperative necessity in Bihar, where the tobacco must be planted and cut in a few months towards the end of the year. In securing a tobacco of sufficiently high grade for the manufacture of cigarettes, it goes without saying that promising results have been secured in the improvement of other varieties of tobacco, which was a consummation much to be desired, because we are reminded that from an economic point of view there are obvious drawbacks to the production of a high grade cigarette tobacco only. The only customer in Bihar for this tobacco is the Peninsular Tobacco Co., as the local dealers do not require this product.—*Madras Mail.*

PHILIPPINE COPRA.

A recent report prepared by the Bureau of Insular Affairs, War Department, Washington, states that the Philippines a few years since were the leading source of the world's copra supply. But the coconut plantations were so seriously injured in 1912 that this youngest and heretofore most rapidly developing of the leading export industries of the islands received a check from which even now it is only beginning to recover, and Philippine copra is still far below its tonnage record of the past.

The unprecedented drought in the early part of 1912 interfered with the flowering of the palms, while storms of great violence swept the plantations during the autumn. As about a year is required for maturing the nuts the double disaster of that year has had a far-reaching effect on exports, which, from 140,536 long tons in 1912, dropped to 80,920 in 1913, with only a nominal recovery to 85,965 in 1914. While war conditions have doubtless tended to check normal trade movement and obscure this recovery in production, exports from August to December, 1914, amounted to 46,836 long tons, against 37,967 in the same period of 1913, and but for price conditions and the disturbed demand of the world market, the forecast is favourable for early resumption of normal output.

In the matter of prices during 1914 the industry fared badly, and the value realised on the slightly larger quantity, amounting to \$7,980,270, was \$1,565,454 below that of 1913. The increasing demand for coconut oil, and its growing use for food preparations in addition to its employment for industrial purposes, which has led to the rapid extension of Philippine copra production, has been characterised by a remarkably steady advance in copra export prices from about 2 cents per lb. a decade ago to over 5½ cents in the closing months of 1913. But a decline was already noticeable in the opening months of 1914, with prices that by July had reached 4½ cents, and the war was doubtless the leading factor in further declines that took export prices below 3½ cents—a reduced remuneration that may tend to affect production of copra even though indications point to an early normal yield of coconuts.

The reduced copra trade of the past two years is subject to some qualification, in view of the development of an export manufacture of coconut oil, which figured as a new item in the trade in this period. A manufacturing plant newly installed at Manila began to make shipments in the early part of 1913, and this new export item has steadily grown in importance, amounting to over \$2,500,000 in 1914. The exports of oil may be roughly estimated to represent the consumption of some 8,000 tons of copra in 1913 and 20,000 in 1914, and these amounts should be considered in connection with the small copra tonnage of those years. The oil trade has been almost exclusively with the United States from the beginning. Exports of the by-products of oil cake have also been a feature of this new manufacturing industry, and were exclusively to Germany, but ceased entirely in July.

OBITUARY.

ROBERT FELLOWES CHISHOLM, F.R.I.B.A.—Mr. Robert F. Chisholm died at his residence in Southsea on May 23rd. He was born in 1839. His father was a black-and-white artist, and he inherited artistic abilities and was a draughtsman of a high order. He was apprenticed to an architect, but an attractive offer having been made to him when he was about twenty years of age, he went out to Calcutta as a railway engineer in 1859. A few years later the attention of the authorities in Madras was drawn to him by his success in an architectural competition, and shortly afterwards he was appointed consulting architect to the Government of Madras. Thenceforward his work was mainly architectural, although he continued to take a keen interest in everything artistic, music, painting, pottery, etc. He remained in Madras till his retirement, when for a short period he worked privately in Bombay and for the Gaekwar of Baroda. The Gaekwar's palace, which he designed, is generally regarded as one of the sights of the city.

Mr. Chisholm was distinguished by his singularly keen appreciation of Indian art, and he has been mentioned as one of the two Government architects who have done more than anyone else to adapt Indian architectural styles to the requirements of modern Government departments. His Christ Church at Cuddapah is considered one of the prettiest of the Madras country churches. He finally left India about 1900, and spent some years in London. His last architectural work was the Christian Science Church in Sloane Street. He retired some five years ago to Southsea.

Mr. Chisholm was elected a member of the Royal Society of Arts in 1896. He took a keen interest in the work of the Indian Section, and frequently spoke in the discussions, especially in those which dealt with artistic subjects. In 1911 he read a paper on "The Taj Mahal, Agra, and its Relations to Indian Architecture," for which he received the Society's silver medal.

JOHN AMORY TRAVERS. — Mr. John Amory Travers, of Tortington House, Arundel, died suddenly of heart failure on the 4th inst., at the age of sixty-seven. He was formerly a member of the well-known City firm of Messrs. Joseph Travers and Sons, Ltd. He was also Chairman of the North Borneo Trading Company, Ltd., and a Director of the Komata Reefs Gold Mining Company, Ltd.

As a prominent member of the Worshipful Company of Fishmongers, Mr. Travers took a deep interest in the Company's charities, being at the time of his death Deputy-Chairman of the Governors of Gresham's School at Holt, in Norfolk. This school was founded in 1554, and is carried on for the higher education of boys under a scheme of the Charity Commissioners.

About ten years ago, when negotiations were proceeding for the proposed amalgamation of the Society of Arts and the London Institution, Mr. Travers was a strong supporter of the scheme, and he was one of the six representatives of the Institution on the joint committee, composed of representatives of the two bodies, which was appointed to consider the matter, and which reported in favour of amalgamation. He was at that time a member of the Society of Arts, having been elected in 1894.

NOTES ON BOOKS.

THE BOOK OF THE FLY. By G. Hurlstone Hardy. London: William Heinemann. 2*s*. 6*d*. net.

Just over a year ago Dr. E. Halford Ross read a paper before the Society on "House-flies and Disease." It was followed by an interesting discussion and some correspondence, to which Major Hardy contributed, and this volume owes its existence in some part to that discussion.

We are hearing a good deal at present about flies and their insanitary habits, which are likely to prove more than usually dangerous at a time when war is being waged over the greater part of Europe, when camps are scattered over a continent, and when the usual sanitary precautions can hardly be taken. The *Journal* has done what it could to spread a knowledge of these injurious creatures, and in a recent number was described the excellent Fly Exhibition now open at the Zoological Gardens, where the visitor may obtain an admirable object-lesson on the ways of these disease-spreading creatures. It is not everyone, however, who can get to Regent's Park, and one must give a cordial welcome to a book which gives so good an account of the fly as Major Hardy presents to us.

Although the fly has long been suspect among men of science, to the uninitiated it has been a harmless, or at worst an annoying, insect. It is high time that the general public should be educated to understand the perils it may bring with it. This task Major Hardy's book is well fitted to perform. It is written in a popular and readable style, and conveys a great amount of information about the various species of fly without being in any way overburdened with technical terms.

Readers of the *Journal* will hardly need to be reminded of the foul habits of the domestic fly how it haunts the most obscene places, and then makes its way, its hairy legs covered with germs and filthiness, direct to our breakfast tables, to leave a trail of possible disease and certain pollution over the sugar basin and the butter dish. All this is well described by Major Hardy, together with a clear physiological account of the various species of fly and their methods of reproduction. It gives one to think when the author mentions that the progeny of a single pair of house-flies may number 500 after one month, 125,000 after two months, and after three months many millions.

INDUSTRIAL TRAINING. By N. B. Dearle. London: P. S. King & Son. 1914.

This book is one of the monographs on subjects connected with economics and political science issued by the London School of Economics under the editorship of the Hon. W. Pember Reeves. It is the result of a laborious and exhaustive investigation into the problems of unemployment in the London building trades, and afterwards extended into the general conditions of technical education in London. It contains a vast amount of information which will be of serious value to all students of these important subjects. It deals not only with industrial education as generally understood, but with all the methods by which the supply of labour is provided in London industries, including apprenticeship, technical instruction in various forms, and the common practice of picking up knowledge of a trade by mere imitation and seeing skilled workers at work.

The author must have given considerable time and careful thought to the acquisition and classification of the varied information he has collected.

This information might perhaps have been more serviceable had it been a little more condensed, for the subject is treated with such minute detail that it is really a little difficult to get anything like a general view of the whole. Still, any student who will take the trouble to follow Mr. Dearle through his long and careful inquiries will be rewarded by the amount of information provided.

THE YEAR-BOOK OF WIRELESS TELEGRAPHY AND TELEPHONY, 1915. London: The Wireless Press, Ltd. 3*s*. 6*d*. net.

The third issue of this useful year-book is a thick volume of some 800 pages, and contains an immense amount of information relating to wireless telegraphy. The great bulk of this, naturally, is of a purely technical kind. Thus we have some 200 pages devoted to laws and regulations of various countries, from the Argentine Republic to Uruguay; about 200 pages are filled with particulars of the various wireless telegraph stations (land and ship) throughout the world; and a long alphabetical list is given of the call letters allotted to these stations. But in addition to these technical details there are a number of articles of more general interest which will appeal to the scientific reader. Professor J. A. Fleming, F.R.S., writes on "The Function of the Earth in Radiotelegraphy"; Mr. H. J. Round on "Wireless Telephony"; Dr. W. Eccles on "International Wireless Telegraphic Research during 1914"; Mr. Archibald Hurd on "Wireless and War at Sea"; Colonel F. N. Maude on "The Influence of Wireless Telegraphy on Modern Strategy"; Mr. A. H. Morse on "Some Applications of Radiotelegraphy"; Mr. R. G. K. Lempfert on "The Application of Wireless Telegraphy to Meteorology," and Mr. Arthur R. Hinks, F.R.S., on "Wireless Telegraphy in Survey."

The year-book has now established its reputation as a thoroughly sound and practical publication, the value of which is well recognised in the wireless world.

MICROMETERS, SLIDE GAUGES, AND CALIPERS. By Alfred W. Marshall, M.I.Mech.E., and George Gentry. London: Percival Marshall & Co. 6*d*. net.

This little handbook forms one of the excellent "Model Engineer" series. The information contained in it has already appeared in the pages of *The Model Engineer*, having been written in reply to inquiries from readers for instruction in the use of fine measuring appliances. It is impossible to exaggerate the value of minutely exact measurement to the engineering mechanic of to-day, and a thorough knowledge of accurate measuring instruments is essential to his success. The principles of micrometers and verniers are very clearly and practically explained by the authors; and the ways are indicated in which mistakes are liable to occur. The illustrations are numerous and good, and help materially to make the text easily comprehensible to the student.

GENERAL NOTES.

AGRICULTURE IN ENGLAND.—Some interesting facts bearing on the great agricultural industries of this country are to be found in a return issued by the Board of Agriculture and Fisheries on "Acreage and Live Stock Returns of England and Wales." From this it appears that of the 37,139,153 acres which make up the total area of England and Wales, 27,114,004 acres were under crops and grass on June 4th last. This is 15,378 acres less than in 1913, and the smallest total returned in any year since 1877. The decline is attributable in the main to the increase in the urban area, and to the constantly expanding demand for land for industrial purposes. A noticeable point, however, is the slackening of the rate of decrease. In addition to the area strictly under crops or grass there are two other categories of land of an agricultural character, namely woodlands and mountain or heath land, which, while the herbage is too sparse or of too poor a quality to be regarded as pasture, is nevertheless utilised for grazing. This latter area was returned in 1914 as 3,781,565 acres, or some 23,500 acres less than in 1913. The inquiry as to the acreage of woodlands was not repeated in 1914, but, assuming that the figure of 1,884,068 acres returned in 1913 has remained practically constant, it would appear that 32,779,637 acres, or 88 per cent. of the total area of England and Wales, is either under cultivation, grazed, or woodland. The total number of agricultural holdings of over one acre in 1914 in England and Wales, viz., 435,124, shows a reduction of 553 as compared with the previous year, a diminution naturally accompanying the decline in the total agricultural area. Holdings of the two smallest classes (1 to 5 and 5 to 20 acres) both show some reduction, but all the other remaining groups show slight increases. The total area under wheat, barley, and oats in England and Wales in 1914 was 5,241,895 acres, or 6,751 acres greater than in 1913. Wheat showed an increase of 105,910, while barley and oats were reduced by 54,085 and 45,074 acres respectively. The acreage under potatoes, 461,621 acres, was 19,586 acres greater than in 1913, and 29,587 acres above the average of the previous ten years. The total number of cattle in 1914 was 5,877,944, an increase of 161,000 as compared with 1913, and the largest number in any year, except 1911, since the returns were first collected. The number of sheep in 1914 was 17,259,694, an increase of 129,408 as compared with 1913, and, apart from that year, the smallest number on record. Of pigs the total number was 2,481,481, which was 379,379 greater than in 1913, and under one per cent. less than in 1912.

FOREIGN MACHINERY IN THE YANGTSZE VALLEY.—According to the American Consul of Chungking, there is an increasing demand in the Mienchow district (Szechuan Province) for articles of foreign manufacture. More sewing machines are sold

than ever before, and there is a good field for knitting machines. Pumping plants could be used not only for irrigation, but for pumping out flooded mines and for raising brine from the salt wells. Modern evaporating machinery could be used to advantage. With present methods it takes three to fifteen years to bore the deepest salt wells; with modern equipment the same work could be done in a few months. There is not likely to be much demand for agricultural machinery, as farms are all too small and labour is too cheap to make such an innovation profitable. Machinery for silk and cotton spinning and weaving could be used to advantage. The greatest obstacle to the development of the district is lack of capital. The Chinese recognise that many improvements are needed, but they seldom have the money necessary to instal them. As the profitable nature of many of these enterprises is well known, it should be possible for foreign companies to sell machinery accompanied by a loan that would be amply secured by the equipment.

New Rubber-curing Process.—A new departure in rubber-curing is described in the *Malay Mail*. The process does not embody any revolutionary changes from present practice so far as coagulating, crêping, or sheeting are concerned. These stages are carried out as before, but a great reduction in the time is claimed to be effected by turning out the sheet or crêpe much thicker than now. The crêpe, or sheet, to quote the specifications, is taken and introduced on top of a movable belt which, rotating in a particular direction, passes under a specially shaped jaw of a hinged top plate, thus imparting a rolling action to the sheet or crêpe. The commencement of the roll having now been attained, this action continues until the formed roll of rubber reaches a certain point in the machine and is ejected. The roll is smoked overnight, and is then ready for shipment. It is claimed by the co-inventors, Mr. Shelton Agar, manager of Kamuning Estate, and Mr. W. T. Platt, of Messrs. Guthrie & Co., Limited, that by the adoption of this machine and the attendant necessary slight changes from prevailing smoking methods, not only will drying sheds become unnecessary, but the finished product will be a better quality. An estate's whole output can be despatched forty-eight hours after tapping. In addition, grades of rubber are reduced to two, viz., one grade for the latex section and one for the scrap.

Asbestos in Tasmania.—The results of the geological reconnaissance of the country between Cape Sorell and Point Hibbs, on the west coast of Tasmania, are given in Bulletin No. 18 of the Geological Survey of that State. Asbestos occurs in this area in a belt of serpentine rocks which outcrop on the southern shore of Macquarie Harbour, at a locality known as Asbestos Point, and a company has been formed to investigate the extent of the asbestos-bearing zone. Trenches cut across the deposit show ramifying veins of chrysotile asbestos varying in width from an inch down to a mere paper-like film. The asbestos fibre is of good quality, and is stated to compare favourably with Canadian asbestos.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 14...Geographical Society, Burlington-gardens, W., 8.30 p.m. Dr. Filippo de Philippi, "Expedition to the Karakoram and Eastern Turkestan."

Tuesday, June 15...Statistical Society, 9, Adelphi-terrace, W.C., 5 p.m. Messrs. B. Mallet and H. C. Strutt, "The Multiplier and Capital Wealth."

Wednesday, June 16...Meteorological Society, 70, Victoria-street, Westminster, S.W., 4.30 p.m. 1. Professor H. H. Turner, "Discontinuities in Meteorological Phenomena." 2. Mr. C. Harding, "Battle Weather in Western Europe, nine months, August, 1914, to April, 1915."

Microscopical Society, 20, Hanover-square, W., 8 p.m. Mr. F. Enock, "On the British Trap-door Spiders."

Thursday, June 17...Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. B. Cummings, "Colonel Montagu, Naturalist." 2. Dr. G. Henderson, "The fibre of *Calotropis procera*, and the cultivation of the plant from an economic point of view." 3. Mr. J. Hopkinson, "The structure of the Rhizopod test." 4. Mr. E. T. Browne, "Medusæ from the Indian Ocean, collected in 1905" 5. Professor A. Dendy, "Report on the Hexactinellid Sponges (Triaxonida) collected by H.M.S. 'Sealark' in the Indian Ocean" 6. —, "Tetraxonida." 7. Mr. J. C. Robson, "On the Cephalopoda obtained by the Percy Sladen Trust Expedition to the Indian Ocean in 1905."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Messrs. T. M. Lowry and P. C. Austin, "The rotatory dispersive power of organic compounds. Part VIII.—Tartaric acid and the tartrates." 2. Mr. B. B. Dey, "A study in the coumarin condensation." 3. Mr. H. K. Sen-Gupta, "The formation of heterocyclic compounds from hydroxymethylene ketones and cyanoacetamide." (Part I.) 4. Messrs. T. M. Lowry and V. Steele, "Nitrocamphor and its derivatives. Part VIII.—The action of formamide on nitrocamphor." 5. Messrs. G. Senter and H. Wood, "Reactivity of the halogens in organic compounds. Part VIII.—Interaction of alkalis and alkali bromoacetates and bromopropionates in methyl alcohol solution and in mixtures of methyl alcohol and water." 6. Messrs. T. M. Lowry and R. G. Parker, "The properties of cold-worked metals. Part II.—Methods of measuring small changes of density produced by annealing."

African Society, Hotel Cecil, Strand, W.C., 8 p.m. Mr. H. W. Fox, "Rhodesia and the War."

Friday, June 18...Water Engineers, Institution of, at the Geological Society, Burlington House, W., 3 p.m. 1. Mr. H. Dewey, "The Effect of Springs upon Water-levels in the Chalk of Eastern Surrey." 2. Mr. P. Griffith, "The Hydro-Geological Conditions of Newbald, East Yorkshire."

Astronomical Society, Burlington House, W., 5 p.m.

Historical Society, 22, Russell-square, W.C., 8.30 p.m. Colonel E. M. Lloyd, "Some Episodes of Waterloo as Illustrations of Historical Evidence."

Journal of the Royal Society of Arts.

No. 3,265. VOL. LXIII.

FRIDAY, JUNE 18, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Sixty-first Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new Fellows, will be held, in accordance with the By-laws, on Wednesday, June 30th, at 4 p.m.

(By order of the Council),

HENRY TRUEMAN WOOD, *Secretary.*

SPECIAL WAR LECTURES.

The Council have arranged with Professor Vivian B. Lewes to give a short course of special lectures during the recess on "Modern Munitions of War." Three lectures will be given at 4.30 p.m. on Wednesday afternoons, July 7th, 14th, and 21st.

The first lecture will deal with "Guns and Propellants," the second with "Mines, Shells, and High Explosives," and the third with "Poison Gases and Incendiary Bombs." The course will be given under the Fothergill Trust.

The lectures will be open to all Fellows of the Society, who can admit their friends personally, or by the usual tickets. Any Fellows requiring further tickets can apply to the Secretary, who will furnish them with any number they may desire for distribution. Tickets will also be issued gratuitously to any persons interested in the subject who may apply to the Secretary.

EXAMINATIONS, 1916.

The first Examinations in 1916 will be held from April 10th–19th, and the second from May 29th–June 7th, inclusive. The last days for receiving entries will be March 13th and April 28th, respectively.

THE VALUE OF BIRDS TO MAN.*

By JAMES BUCKLAND.

NUMBER, FECUNDITY, AND VORACITY OF INSECTS.

Man imagines himself to be the dominant power on the earth. He is nothing of the sort. The true lords of the universe are the insects. While it is true that man has invented and perfected so many destructive agencies that he has attained to a predominance over the most fierce and powerful mammals and the most deadly reptiles, it is also true that in face of an attack of insects he and all his works are set at naught.

Few people know how enormous is the number of insect species or how amazing is their power of multiplication. The number of insect species is greater by far than that of the species of all other living creatures combined. Over 300,000 have been described, and it is considered not improbable that twice that number remain to be described. Practically all living animals, as well as most plants, furnish food for these incomputable hordes.

The fecundity of certain insect forms is astounding, the numbers bred reaching such prodigious proportions as to be almost beyond belief. Riley once computed that the hop aphis, developing thirteen generations in a single year, would, if unchecked to the end of the twelfth generation, have multiplied to the inconceivable number of ten sextillions of individuals. Noting the preceding, Forbush says if this brood were marshalled in line, ten to the inch, it would extend to a point so sunk in the profundity of space that light from the head of the procession, travelling at the rate of 184,000 miles per second, would require 2,500 years in which to reach the earth.

Kirkland has computed that one pair of gypsy moths, if unchecked, would produce enough

* Reprinted from the Report of the Smithsonian Institution.

progeny in eight years to destroy all the foliage in the United States.

A Canadian entomologist states that a single pair of potato bugs, or Colorado beetles as we call them, would, without check, increase in one season to 60,000,000. At this rate of multiplication the disappearance of the potato plant would not be long delayed. The chinch bug, a fecund and destructive pest, has been found in a clump of grass 8 in. in diameter to the number of 20,000. The progeny of this colony alone, if unchecked, would soon become incomputable hordes, devastating wide areas of the earth's surface. Those of you who have been in South Africa probably have seen locusts in flight which filled the air and hid the sun. What a potency for evil lies hidden in the tiny but innumerable eggs of these ravening pests! If every egg was permitted to hatch and every young locust to come to maturity, the consequences would be too dreadful to contemplate.

The voracity of insects is almost as astounding as their power of reproduction. The daily ration in leaves of a caterpillar is equal to twice its own weight. If a horse were to feed at the same rate, he would have to eat a ton of hay every twenty-four hours. Forbush says that a certain flesh-feeding larva will consume in twenty-four hours 200 times its original weight, a parallel to which, in the human race, would be an infant consuming, in the first day of its existence, 1,500 lbs. of beef. Trouvelot, who made a special study of the subject, affirms that the food taken by a single silkworm in fifty-six days equals in weight 86,000 times its original weight at hatching. What a destruction this single species of insect could make if only a one-hundredth part of the eggs laid came to maturity!

Mission of the Birds in Organic Nature.

Who or what is it that prevents these ravening hordes from overrunning the earth and consuming the food supply of all? It is not man. Man, by the use of mechanically applied poisons, which are expensive, unnatural, and dangerous, is able to repel to an extent the attacks on his orchard and garden. Out in the fields and in the forests he becomes, before any very great irruption of insects, a panic-stricken fugitive. Neither is it disease, or the weather, or animals, or fungi, or parasitic and predaceous insects within their own ranks. However large may be the share of these particular natural agencies in keeping insects in check, experience has shown that it is lamentably insufficient. Then what is it? The bird. Bird life, by reason of its predominating insect diet, is the most indispensable balancing force in nature.

Man at War with Nature's Laws.

Yet man has been engaged in the past half century in the blind and wanton destruction of this essential part of nature's great plan. He has taken no thought of the needs of the hour, nor concerned himself with the wants and claims of those to come. Within the space of a few years, under no constraint of necessity, he has carried out a policy of destruction more effective than that accomplished in centuries by the slow processes of nature. Armed with a weapon that annihilates space, he has constituted himself the master and the ruler of the animal world, and has delegated to himself the right to adopt a utilitarian standard by which he measures the value of all other forms of life. It is not for man to say what shall live and what shall be destroyed. The whole system of nature is in exquisite poise, and it is not possible to lay rough hands upon it without disturbing it in directions and on a scale which at the time may not be guessed at. If we remove or reduce the working power of one living organism which acts as a check on another, the latter, freed from restraint, will inevitably multiply. As we destroy the insect-eating birds the insects on which they prey will multiply to scourge us as Egyptian plagues.

Serious Consequences of Bird Destruction.

Some years ago the agriculturists of Hungary, moved to the insane step by ignorance and prejudice, succeeded in getting the sparrow (*Passer domesticus*) doomed to destruction. Within five years the country was overrun with insects, and these same men were crying frantically for the bird to be given back to them, lest they should perish. The sparrow was brought back, and, driving out the hordes of devastating insects, proved the salvation of the country.

In the Island of Bourbon once, because of the same ignorance and prejudice, a price was set on each martin's head. The birds all but disappeared, and grasshoppers took possession of the island. The edict of banishment was hurriedly revoked and the exile recalled. Fortunate, indeed, was it for the Island of Bourbon that the bird was not beyond recall.

During the year 1861 the harvests of France gave an unusually poor return, and a commission was appointed at the instance of the Minister of Agriculture to investigate the cause of the deficiency. By this commission the deficiency was attributed to the ravages of insects which it was the function of certain birds to check. These birds, it appeared, had been shot, snared, and trapped throughout the country in such numbers that but little repressive influence had been exerted upon the insects. It was concluded that by no other agency than the birds could the ravages of insects be kept down, and the commission called for prompt and energetic remedies to prevent the destruction of birds.

For some years prior to 1877 vast numbers of red-winged blackbirds were poisoned in the spring and autumn around the cornfields of Nebraska. This was done in the belief that the blackbirds were damaging the crops, especially the wheat. Great numbers of prairie chicken, quail, plover, and various other insect-eating species were destroyed at the same time by eating the poisoned grain. Then came 1877, and with it Nemesis. The locusts appeared in countless numbers. There were no birds to eat them, and Nebraska mourned.

In 1895 the ravages of two species of cut-worms and some ten species of locusts produced a famine in the region of Ekaterinburg, which is in Russian Siberia. The local Society of Natural Sciences inquired into the cause which had permitted such a numerous propagation of insect pests, and reported that it was due to the almost complete destruction of birds, most of which had been killed and sent abroad by waggon loads for millinery purposes.

Those grass ticks which now make the keeping of most breeds of cattle impossible in Jamaica are not mentioned in the records of the early nineteenth century. The appalling destruction in more recent years of insect-eating birds, chiefly to supply the demands of the millinery market, has led to an inordinate increase of the ticks and to the dying out of all but Indian cattle. This correlation of birds and ticks - to say nothing of mosquitoes and other insect plagues in Jamaica—was put fully and circumstantially before the Secretary of State for the Colonies by a deputation in 1909.

E. D. Morel has recently pointed out how the reckless destruction of the guinea-fowl (*Numida*) in French West Africa is coincident with the increase of certain germ diseases, and, above all, with ravages to crops on the part of the larger insects, especially beetles, the grubs of which were devoured by the guinea-fowl, which scratched them out of the ground.

Though I could give a hundred cases similar to the foregoing, I must rely on the few I have cited to show that the wholesale destruction of birds is surely followed by disaster to man.

Value of the Bird in checking Insect Irruptions.

When the Mormons first settled in Utah, their crops were destroyed utterly by myriads of black crickets that streamed down from the mountains. Promising fields of wheat in the morning were by evening as bare as though the land had not been sown. The first year's crop having been destroyed, the Mormons had sowed seed the second year, and again the crop promised well. But again the crickets appeared, devouring every blade of wheat, and the followers of Joseph Smith were on the verge of starvation. At this juncture Franklin's gull came by hundreds of thousands, and, feeding greedily on the crickets, freed the fields of the pest. The settlers at Salt Lake regarded the advent of the gulls as a heaven sent miracle, and practically canonised the birds.

Since that hour this black-headed gull has remained a faithful servitor of the farmers of Utah. A monument to this bird has been erected in Salt Lake City, thus showing a befitting and seemly sense of gratitude for its inestimable services in guarding the State from the ravages of insects.

It is a common practice with all settlers in a new country at once to set about killing the native birds in a thoughtless and foolhardy manner. This stupid practice is all the more deplorable, because an enormous increase of insect pests invariably attends the operations of the pioneer agriculturist. Finding in cultivated crops new and more succulent sources of food supply, insects change their primitive habits, to swarm and multiply exceedingly upon the fertile fields of man's creation.

When the farmers in New Zealand began to break the virgin soil on an extensive scale, a certain caterpillar, which hitherto had gleaned a somewhat meagre sustenance from the scanty native verdure of the open lands, disappeared from its old haunts and attacked the cultivated areas. So speedily did it increase by reason of a more favourable environment that it soon became a blasting plague. It came not singly, nor even in battalions, but in mighty armies which laid waste the land. I have seen these atoms cover the pastures in such numbers as to make the green one brown. I have seen countless millions of them pass out of one corn-field, having stripped every stalk bare, cross the road in solid phalanx, and pass into another. I have seen big mobs of sheep mustered in hot haste and driven to and fro over these serried ranks that they might crush them with their scurrying feet. I have seen every horse roller in a district brought up hurriedly, like steam engines to a fire, and drawn backward and forwards over the crawling masses until the cylinders stuck fast in a mire of squashed insects. I have seen huge ditches dug in an attempt to stop the invaders' progress. The effort was as futile as that of a child who builds a bank of sand by the sea, thinking it will stem the oncoming tide. Even railway trains were brought to a stand-still, the wheels of the engines being unable to grip the rails owing to the hordes of caterpillars which were crossing the line.

In time it became abundantly clear that if this disastrous condition of affairs continued it would be useless to attempt to carry on agriculture in New Zealand. Realising that any attempt which they might make to rid the smitten land of the plague would be but a mockery, the farmers turned their eyes longingly to the natural enemy of the caterpillar—the bird. But the native

birds—though they had lived in closest companionship with the Maoris—had been taught the treachery of the white man in a school that reeked with blood, and those that had not been killed had retreated from the vicinity of the settlements, visiting the insect-ridden fields occasionally only.

Wherefore insectivorous birds from the old country were introduced, and the one that multiplied most rapidly was the common house sparrow. And *Passer domesticus* soon cut short the career of the caterpillars.

As digestion is exceedingly rapid in birds, and as they feed for the most part throughout the day, they are peculiarly adapted for the suppression of abnormal outbreaks of vegetable as well as of animal life.

That formidable imported weed, the Scotch thistle, threatened at one time to overrun the whole of New Zealand. Much time and money was spent by the settlers in cutting off the plants close to the ground, and in pouring turpentine upon the split stumps, hoping thereby to kill the roots. Vain labour. The wind-driven clouds of thistledown, which were planting the weed far and wide, grew yearly denser and more frequent. At length the fields became a packed growth of prickly plants, which nothing could face.

The sparrows took to eating the seed. In tens of thousands they fed on it, giving it the preference of all other hard food, and the weed was conquered.

To-day in New Zealand the sparrow is looked upon as an impudent thief without a redeeming feature in its character. No one, of course, can say what would happen if the bird was dismissed from the country, though it is probable that the Dominion would be again overrun with caterpillars and thistles. Setting aside this hypothetical question, the good the sparrow does must far outweigh the evil. This statement receives confirmation in the bountiful harvests with which New Zealand is blessed. Never were the sparrows more numerous; never the complaints against them more bitter; yet the yield of grain is without precedent.

The growling of the New Zealand farmer at the sparrow justifies Virgil's complaint of the "miserly husbandman." Miserly, indeed, and blind. Not a grain will he give to the bird which has laboured unceasingly with him for the production of his crops; but whole fields of wheat to the caterpillar.

Parenthetically I may mention that, though I have written here in defence of the introduction of the European sparrow into New Zealand, I am not an advocate of acclimatisation. It is true that one can point to cases where a foreign bird has been introduced to perform the function of a native species that has been driven out, and where that function has been performed satisfactorily. But, as a rule, such substitutions are fraught with danger. Birds so rapidly change their habits in new surroundings that few species remain loyal to the reputation for honesty which they enjoyed in the land of their origin. Like most aliens, it would have been better had they remained in their own country. Although the spread of civilisation unconsciously demands some victims, man and indigenous birds can, speaking generally, occupy the same territory without much difficulty. If one requires proof of this, one has but to turn one's thoughts to British India, where native birds of all kinds, owing to the protection accorded them by the Hindu doctrine of the sanctity of all life, are found living in closest proximity to dense human populations.

The moral of all of which is that it behoves every man who has the welfare of his country at heart to do all in his power to foster native birds.

In Australia a plague of grasshoppers periodically visits the fields to devour the crops. The ruin they would otherwise bring on the farmer is averted by the good offices of ibises and other native birds. As a destroyer of grasshoppers, the straw-necked ibis (*Carphibis spinicollis*) has no equal among birds. Dudley Le Souef, the director of the Melbourne Zoological Gardens, some years ago visited a rookery of this bird in the Riverina, and, after a careful estimate, came to the conclusion that the minimum number of birds breeding there was 200,000. He procured a number of specimens, and ascertained by actual counting that the contents of an average crop of an adult bird were 2,410 young grasshoppers, five fresh-water snails, and several caterpillars, which, multiplied by 200,000, amounts to a total of four hundred and eighty-two million and odd grasshoppers, as well as vast numbers of caterpillars and snails. "Then, again," says Mr. Le Souef, "the average number of young is about two and one half to each pair of parent birds, and the contents of their stomachs must reach an enormous total, as they all seemed gorged with food."

As this enormous amount of food is being eaten every day by ibises in Australia during the hatching time of the grasshoppers, some little idea can be formed of the immense utility of those birds to the farmer. Without them the balance of nature would be disturbed and successful agriculture would be impossible.

In addition to its great value as a destroyer of all devouring insects, the straw-necked ibis feeds with avidity on the fresh water snail—the host of the dreaded liver fluke, which sheep so easily get in certain damp localities.

Were it not for the locust birds, who breed in localities in which the locusts have deposited their eggs, and who spend their lives in combating the locust peril, there are whole districts in South Africa in which agriculture would perish.

THE VALUE OF BIRDS IN FORESTS.

Omitting all mention of many another instance of the quelling of insect outbreaks by birds, I will pass at once to the consideration of those perennial services which act as a constant check on the undue increase of insects, rodents, weeds, and other pests.

Birds attain their greatest usefulness in the forests, because the conditions there closely approach the primeval.

Forest trees have their natural insect foes, to which they give food and shelter, and these insects in turn have their natural enemies among the birds, to which the tree also gives food and shelter. Hence it follows that the existence of each one of these forms of life is dependent upon the existence of the others. But for the trees the insects would perish, and but for the insects the birds would perish, and but for the birds the trees would perish; and, to follow the inexorable laws of nature to the conclusion of their awful vengeance, but for the trees the world would perish.

Consider for a moment the life of a tree in connection with the insects that prey upon it. At the very beginning, before the seed or nut has germinated, it may be entered by a grub which destroys it. Should, however, the seed or nut be permitted to grow, the roots of the seedling may be attacked by beetles. Escaping this danger, a worm lays its eggs in the cracks of the bark. On hatching, the worm or borer perforates a hole in the stem. This hole, admitting water from every passing shower, causes a decay in the wood to commence, from which the tree may never recover. Other borers feed upon the bark, eating the soft inner layer and the sap. The twigs are affected by the larvæ of certain beetles, which act as girdlers, sometimes destroying limbs over an inch in diameter. Weevils bore under the bark and into the pith, making excavations in which the eggs are laid. For the same purpose the cicada makes a terrible wound, which often proves fatal. The limbs of trees are affected by aphides, which puncture them and feed upon their juices, exhausting the sap. Many species of plant lice and scale insects infest trees, doing great damage, while over one hundred different species of gall flies are parasitic upon them. The buds of trees are entered and destroyed by the larvæ of certain moths, while the leaves are devoured by caterpillars. To take the oak as an example, it is known that altogether over five hundred species of insects prey upon it. Finally, be it remembered that in the bark and in the underlying tissues lie the vital energies of a tree.

It is difficult to perceive the usefulness of these insects which feed on the different parts of the tree, though they may, perhaps, when in normal numbers, exert a useful influence by a healthful and necessary pruning. It is certain, however, that if they were not in turn preyed upon by birds they would so increase in numbers that the tree could not survive the injuries they would inflict.

How dependent trees are on birds for their existence may be gathered from the following illustration: As many of you probably know, trees breathe through their leaves. Consequently, if the buds of the leaves are prevented from developing, or are eaten, when developed, by caterpillars, the tree is weakened. Many coniferous trees will die if stripped of their foliage for one year. Deciduous trees, if deprived of their respiratory organs for several years in succession, will also perish, though these trees linger as a rule for two or even three years before finally succumbing.

Nor is injury to its breathing organs the only danger to which a tree afflicted in this way is subjected. The tree, being in a weakened condition, is at once beset by beetles and other borers, who, multiplying rapidly under such favourable conditions, tunnel under the bark until all the vital tissues of the poor tree are wasted. Thus a tree which might have recovered from the injury to its lungs falls a victim to the attacks of an insidious enemy which took advantage of its enfeebled state.

Woodpeckers or other birds of similar feeding habits would have flown to the rescue of the tree and possibly saved its life; but when that corrective influence is missing, the tree must die.

This illustration of the dependence of the tree on the bird and of the bird on the tree is, of course, but one of a long series that could be cited, and it is because of this most delicate adjustment between the tree, the insect, and the bird that I regard as profoundly true Frank M. Chapman's statement, "that it can be clearly demonstrated that if we should lose our birds we should lose our forests."

It is an ignorant schoolboy who does not know that if we lost our forests we should lose also the moisture necessary for the production of crops upon which man is dependent for his living.

If, in his arrogance and folly, man exterminated the bird, thinking himself capable of taking its place, he might be able to make shift with his sprays to save some portion at least of his orchards and gardens; but of what avail would be his efforts to protect from the insects the forests of America and Africa, the jungles of Asia, or the bush of Australia? Should he not, then, protect by every means in his power every one of the forest birds, who, as a matter of course and without trouble or expense to him, ordinarily accomplish, on his behalf, the herculean task of saving the lives of the trees? One would think so. Yet in these very regions there are being killed annually millions of the feathered guardians of the tree,

and killed, too, for no worthier purpose than that, dead, they may defame a woman's head.

The Value of the Bird in the Orchard.

For man's purposes the work of the bird in the orchard is not so thorough as that done by them in the forest. Birds are the slaves of nature, and, in the main, nature's endeavours are put forth only to produce such fruits as will insure the perpetuity of each species of tree. With man the case is altogether different. His main object is not the propagation of trees, but the production of a giant gooseberry. Moreover, by introducing arsenical spraying, tarred and greased bands, and other devices to counteract the evil action of insects, he has, to a certain extent, taken upon himself the office of the bird. In this he is wise, for it must be admitted that if he wishes a large crop of fruit he must himself prevent the inroads of those insects which attack the fruit directly. It cannot be expected of the bird that it will become an efficient ally of man in protecting the artificially produced fruit from the attacks of the numerous insects that are drawn to the orchard by a vastly increased quantity of fruit of a vastly better quality than the natural product.

For all that, fruit growers are largely indebted to the bird for a great part of their annual crop.

In the Union of South Africa, for instance, it is found that near towns, where the birds have been more especially persecuted and driven away, the growing of fruit and other market produce has become increasingly difficult, or even impossible, owing to the prevalence of insect pests which are not affected by spraying operations.

But let us suppose for a moment—though the supposition is absurd—that the modern fruit grower could do without the services of the bird. Would that give him a right to slay it? Apart altogether from the agriculturist, what of the millions of people who, as an increment to their ordinary livelihood, grow fruit, but who cannot afford either the time or the money to treat their trees in the most approved and scientific way?

What would happen to this poorer class of fruit growers if they were deprived of the services of the bird is best seen in what happened to Frederick the Great. This worthy, in a fit of passion because a flock of sparrows had pecked at some of his cherries, ordered every small bird that could be searched out to be instantly killed. Within two years his cherry trees, though bare of fruit, were weighed down with a splendid crop of caterpillars.

Call the bird in the orchard an evil, if you will; but it is a necessary evil, and the fruit grower must make up his mind to pay the bird its wages lest worse befall.

The Services of the Bird in the Garden.

The garden is the insect's paradise. It fares sumptuously every day on the most succulent of vegetable foods. Every opportunity is thus offered for its increase. The greatest insect enemy of the garden is a small, dull-coloured, hairless caterpillar known as the cutworm, which is the larva of a Noctuid moth. This chief of the brigand band of garden pests usually hides during the day beneath matted grass or under the loose soil along the rows of plants. It comes forth at dusk to feed. The bird is abroad at the first peep of day, and it finds the robber worm in the morning before it has retreated to its place of concealment.

But the early bird has to come stealthily to the garden to catch the worm. Its visits are regarded by man with more than suspicion, and it is fortunate if it escapes with its life. In consequence it snaps up a caterpillar and is off again, leavings thousands it would have eaten, if unmolested, to run riot amongst the vegetables.

Occasionally a bird more bold than its fellows will visit the garden in broad daylight to dig the cutworms out of their hiding-places. Nature never having begrudged it the reward of its toil, the bird takes a few peas before leaving.

The gardener notices the damage done to his peas, and next morning is up betimes. He sees the bird running along a row of peas, stopping frequently to peck at something on the ground. There is a loud explosion, followed by a puff of smoke. The smoke slowly drifts away to disclose a bird lying dead.

Caterpillars are not gifted with voice; if they were, they would scarce forbear to cheer.

The bird is dead. Mark the sequel. One fine morning the gardener issues proudly forth to cut his mammoth cabbage the one with which he intends to put to utter confusion all other competitors at the local fruit and flower show. Alas for human hopes, and the depredations of caterpillars! The cabbage is riddled like a colander.

The gardener when he shot the bird forgot, if, indeed, he ever knew, that the ancient law forbade a muzzle to the ox that thrashed out the corn.

Utility of Birds in the Meadow.

Each season, until hay-making commences, the grass offers cover and shelter for the nests of such birds as breed on the ground. The fields also provide food for birds, and for the insects on which birds feed. Thus there is established a natural interrelation and interdependence between the bird and its food and shelter—that is to say, the insects and the grass. This simulates the condition of the earth before man made discord in the grand harmony of nature's laws.

Where the birds of the field are undisturbed they tend to hold the grass insects in check. On the other hand, when the numbers of birds in the field are for any reason insufficient, the insects increase.

Here is an instance of this: Some years ago in Bridgewater, Mass., a great battue was held by the ignorant townspeople in the spring of the year, and so many field birds were killed that their dead bodies were ploughed into the land for manure. The following summer whole fields of grass withered away and died. This was due solely to the fact that the number of field birds had been reduced, and in consequence the pressure which nature demands the field birds shall exert upon the field insect had been released.

Again, at one time in New Zealand it was no uncommon thing to see English grass wither up in large parches, as though scorched by fire. This was due to the work of a crane fly and click beetle, the larvæ of both of which were addicted to the habit of eating the roots of the grass, just under the surface. English grass was then comparatively limited in the up-country districts, and, as there are large tracts of land in New Zealand destitute of native grasses, the depredations of these insects became a serious matter to those settlers who had stock to feed and who were relying on the English grass to feed it. It was all the more serious because the insects were without any natural check, the native birds which had kept them in subjection before the advent of the white man having been either killed or driven from the vicinity of the homesteads. So the beetles continued to make merry, to marry, and to multiply. In a corresponding ratio the grass continued to fade, to wither, and to die.

Then came the English starling, and so voraciously did it feed on the larvæ that soon all was green again.

A case similar to the foregoing occurred about five years ago in the Illawarra district of Australia, where, owing to the ruthless destruction of wild bird life, grubs took possession of the land, and, eating out the grass by the roots, transformed what had been a rich pastural country into an unprofitable waste.

Without the aid of birds grass could not be grown. The grub of a single species of beetle, if unchecked in its multiplication, could destroy all the roots in our meadows; or any one of the several species of cutworms, if its reproduction was not restrained by birds, might be sufficient to destroy all the verdure above ground.

Hawks and Owls.

The injury to trees, crops, and grass by insects is not the only evil that threatens man as a sequence to the destruction of birds. Rapacious birds hold a chief place among the forces which are appointed to hold in check small rodents, which breed rapidly, and unless kept within bounds are exceedingly destructive. Yet, notwithstanding the unanimous testimony of careful students of birds and their food habits to the effect that almost all hawks and owls are beneficial, a widespread prejudice still exists against them. They are slain as relentlessly as if they were enemies instead of friends of the farmer.

The destructive habits of the small rodents, which are the natural prey of hawks and owls, are much the same all the world round. They do an incalculable amount of damage to standing corn, to corn in the stock or when stacked, to grain, to root crops when growing or when piled on the ground or stored in pits, to orchards and forest trees, to the roots of clover and other grasses, to ground growing fruit, and to gardens, both flower and vegetable. In addition to this list of crimes, certain rodents are active agents in carrying and disseminating the germs of plague and other diseases.

Here in England though on account of their small size and secretive habits they are often undiscerned by man's dull eyes--they swarm in such numbers in the fields and hedgerows that the damage they do must prove a steady drain on the resources of the farmer.

The number of small rodents eaten by the rapacious birds is almost as remarkable in proportion to their size as is the number of insects eaten by small insectivorous birds. During the summer of 1890 a pair of barn owls occupied a tower in a building at Washington. After their departure there were found in the regurgitated pellets, with which the floor was strewn, 454 skulls of small rodents.

The young of hawks and owls remain a long time in the nest, and require a great quantity of food. During this period the resources of the parents must be taxed excessively in the effort to satisfy the hunger cravings of their offspring, and it is not to be wondered at if some individuals are forced occasionally to snap up a chicken. But what is the worth of the chicken, or of the young pheasant, occasionally taken, compared with the hundreds of thousands of pounds worth of damage that is wrought in the orchards and fields by rodents that hawks and owls, had they been spared, would have fed upon for the maintenance of their species?

In 1885 the Legislature of Pennsylvania passed an Act, known as the "Scalp Act," which provided a bounty of 50 cents each on hawks and owls killed within the State limits, and a fee of 20 cents to the notary taking the affidavit. As the result of this act, \$90,000 was paid in bounties during the year and a half subsequent to the passage of the Act. An irruption of small rodents followed, and did damage to the agricultural interests of the State amounting to \$3,850,000. And even these figures, enormous as they are, do not represent the entire loss.

Years must elapse before the balance of nature, which was destroyed, can be restored.

In Montana the destruction of hawks and owls was so complete that rodents, freed from the pressure of their natural check, became as one of the plagues of the Book of Exodus. Then the legislature passed a law offering bounties for the destruction of these four-footed pests. During six months of 1887 such large sums were paid out in bounties for the destruction of small rodents—a work that the hawks and owls had previously done free of charge—that a special session of the legislature was called to repeal the Act, lest it should bankrupt the State.

In 1907 Nevada went through a very trying experience with mice, while Utah, Wyoming, California, and several States farther east have all had occasion bitterly to rue the day that they shot their hawks and owls.

But the destruction of small rodents is not the only function of rapacious birds in the economy of nature. Several species are voracious insect feeders. Nor is this all. It is well known that when small insectivorous birds increase abnormally in numbers they, too, become a pest. Hawks and owls materially assist those other agencies of nature which act as a check on the undue increase of small birds. If rapacious birds were rigorously protected in this country we should have fewer complaints of the damage done by sparrows.

Birds of prey, if unmolested, not only prevent the overproduction of small birds, but they also confer a salutary benefit on each species on which they prey by checking the propagation of weakness or disease by killing off the sickly and most unfit individuals, for these are the most easily seen and the most readily captured. This is particularly true of game fowl, and one of the most plausible hypotheses explanatory of the occasional outbreaks of disease among grouse has been the removal of this corrective by ignorant gamekeepers.

Yet it is my belief that nothing but a miracle will ever make these men see the error of their ways.

The Economic Value of the White Heron.

The destruction of the white heron for its scapular plumes has robbed half the world of a bird which is most useful to man. It never touches grain, but feeds solely near water and over damp ground, the breeding places of innumerable batrachians, small crustaceans, and pestiferous insects, all of which directly or indirectly injuriously affect crops in the neighbourhood. The presence of the white heron in the rice fields, for instance, is distinctly beneficial to the farmer, and rice is one of the most extensively grown crops of India and of China.

In Australia the slaughter of this and other wading birds for their plumage is causing in that country a decline in its fish resources. It is the destruction of these birds which has led to the ever-increasing multitudes of crustaceans which destroy the fish spawn and the young fish hatching out in the Coorong and in the lakes at the Murray Mouth.

In his report on Egypt for the year 1912 Lord Kitchener stated that the indiscriminate destruction of bird life had allowed an enormous increase of insect pests, steps for the combating of which were to be taken. Lord Kitchener knew that in spite of the improved methods of fighting insects there was only one step that he could take that would be effective. A Khedivial decree was issued forbidding the catching or killing of, or taking the eggs of, Egypt's insectivorous birds. In issuing this decree the fact was not lost sight of that in the valley of the Nile the egret is one of nature's checks on the cotton worm.

White herons consume many flies, as well as the larvæ of insects in water. This fact is well known to those who have watched the habits of oxen and buffalo in Asia or Egypt. There the smaller white herons—the paddy birds of India—live with the oxen or the buffaloes, and pick the flies or the ticks from their bodies.

The late George Grenfell noted once on the Congo how a dying white heron, which he had shot and put into his canoe, roused itself, even on the approach of death, to snap at the tsetse flies which were settling on his boatman's legs.

Value of Birds to Live Stock.

The injury done to domestic animals by biting and parasitic insects is very great. Herds of cattle are often stampeded by these tormenting creatures, which carry disease and death among them. Another great affliction is the warble, which is a small tumour produced by the larva of the gadfly on the backs of cattle, and the constant irritation of which causes considerable depreciation in the value of hides, besides a lessened quantity and poorer quality of beef.

Horses, sheep, and other farm animals are subject to the attacks of similar parasites and other persecuting insect foes.

If it were not for the services the bird renders in alighting on animals in search of these parasites, or in catching the flies on the wing, or in eating them in the embryo state, man would be unable to keep his live stock.

More than this, man himself would be unable to inhabit many places on the earth which he now cultivates, or where he carries on other lucrative industries.

Shore Birds and Disease.

Deadly maladies are carried about by the myriads of mosquitoes and flies that abound on the coasts of tropical and subtropical countries.

Yet the shore birds, which render invaluable services to man by destroying these venomous pests, are thoughtlessly killed by him in countless thousands.

To his honour, be it said, one of the first acts of Mr. Wilson, when he became President of the United States, was to issue an Executive order prohibiting, under heavy penalties for infraction, the destruction of any wild bird in the Canal Zone.

Game Birds as Weed Destroyers.

Unquestionably weeds serve a useful purpose in nature, but that purpose is not the occupation of cultivated land. Without check they would speedily choke all grain to death.

Constant use of harrows and hoes will do much on farm lands and in gardens to keep down weeds, but as most earth is full of weed seed, which retains its vitality for years, the life of the tiller of the soil is one continuous struggle against these troublesome plants. In this battle the bird is of great assistance, for the number of weed seeds eaten by birds on cultivated land must be beyond any assignable quantity.

Game birds generally are the greatest eaters of weed seeds. They are also useful to man in several other ways. Not only do they devour mature locusts, but they scratch up and eat the eggs. They also consume in large quantities termites and other equally pernicious insects. The reckless shooting of game birds is to be deprecated. They are of far more use alive than in swelling the bag of the sportsman.

The quail is perhaps the greatest weed destroyer of all the game birds. It is doubtful, indeed, if the quail is not more useful to man than any other bird. It is very nearly wholly beneficial. During spring and summer it feeds on many of the most destructive of insects, and in autumn and winter it eats an enormous amount of seeds of many harmful weeds.

The report of the United States Biological Survey says :—

"It is reasonable to suppose that in the States of Virginia and North Carolina from September 1st to April 30th there were four quail to each square mile of land. The crop of each bird holds half an ounce of seed, and is filled twice a day. Since at each of these two daily meals harmful weed seeds constitute at least half the contents of the crop, a half ounce daily is consumed by each bird. On this basis the total consumption of harmful weed seeds by quail from September to April in Virginia and North Carolina amounts to 1,341 tons. As destructive insects form about one-third of the bird's food from June to August, quail consume 341 tons of these pests in these States within those two months."

But perhaps the most valuable service that quail render the people of the United States is the greedy way in which—and they stand almost alone among birds in this particular taste—they eat the evil-smelling potato bug.

In addition to this inestimable service, it is partially due to this bird that the cotton boll weevil has not swept over the entire cotton belt of America, bringing ruin to thousands of human beings on both sides of the Atlantic.

While speaking of the services which the quail renders to man, I may mention that there is—now that Great Britain has harnessed the Nile—a plain economic reason for our revolt against the present day practice of killing Egyptian quail, and shipping them abroad by hundreds of thousands to tickle the palate of gourmands.

The Bird as a Scavenger.

The fishing population of these islands has declared war on the gulls, and is demanding the withdrawal of certain species from the list of protected birds, on account of the damage they are alleged to do to the fishing industry. People who believe fishermen's tales are apt to be duped and led into repeated errors. The gull is a surface feeder. It may occasionally levy toll on useful fish, but to say that it does any appreciable injury to the fishing business is absurd.

On the other hand, the presence of the gull is essential to man's health. While the bird fulfils many useful minor offices – such as destroying larvae in land along the seaboard and in eating enemies of fish that are exposed during low tide —its chief function in the economy of nature is that of scavenger of the harbours and of the littoral, just as vultures are the scavengers of the mainland. The wholesale destruction of gulls for their plumage in Yucatan was followed by a great increase of human mortality among the inhabitants of the coast, which mortality was irrefutably due to the loss of the birds that had kept the harbours and bays free from the decaying matter which the sea is constantly casting ashore.

I wonder if these men who wish the gull destroyed ever give a thought to what would happen to their own villages if this bird was not present to eat the refuse they throw about? Or, again, if they ever reflect on that feeling of relief they experience when in thick weather they hear, through the fog, the clamour of these feathered bell buoys, warning them that they are nearing rock or bar?

The Bird as a Guano Producer.

Now that I am on the subject of pelagic birds, I will speak of their value as guano producers.

Undoubtedly the present enormous trade in fertilisers owes its origin to the bird, for the fertilising properties of the phosphoric acid and nitrogen contained in fish was not recognised until guano—which is the excrement of sea

birds mixed with fish—became a stimulus to intensive agriculture.

The value of guano as a fertiliser was known to the people of Peru in the time of the Incas, though the nineteenth century had dawned before the information was carried to Europe by Humboldt. Under the rule of the monarchs of old Peru the birds were rigorously protected and the guano deposits carefully guarded. Three centuries later these protective measures materialised in a source of revenue to the country. Generation after generation of sea birds had placed on their breeding grounds deposits of guano which, in 1853, were estimated by the Peruvian authorities to be worth $620,000,000.

It is our pleasure to think of the Incas as barbarians and to look upon their times as dark and rude. In our own enlightened age we allow the agents of the millinery interest to kill at one fell swoop over a quarter of a million sea birds on an island valuable for its guano deposits.

Value of Wild Bird Life as a Food Supply.

Under certain conditions wild bird life is invaluable to man as a food supply. The pioneer must—at any rate, at the commencement of his farming operations—live in great part on the wild products of the earth. In days gone by the forerunner of civilisation could confidently rely on his gun to keep his larder constantly stocked with edible birds. Now, in many parts of the world, he is confronted with an alarming scarcity of this kind of food. The great straits to which the pioneer of the future will be reduced on account of the present-day slaughter of valuable bird life is foreshadowed by what is happening to-day in Hudson Bay. Fifty years ago the number of wild duck in North America was beyond computation. But man could not slay this bird fast enough to glut his blood lust. Sportsmen, professional hunters, and agents of the millinery interest smote them by the million. Such blind and wanton butchery could have but one result. Ducks are now so scarce along the west coast of Hudson Bay, where there are no moose, caribou are scarce, and the fishing is poor, that the people living there, who had always depended on the ducks they could pack away in the autumn, find it difficult to get sufficient food to carry them through the winter.

The Æsthetic and Sentimental Value of Birds.

Omitting all mention of various other material benefits which birds confer on man, I will, before concluding, notice briefly their æsthetic and sentimental values.

Bird life is the part of the creation in which nature has done more in the way of bestowing mental benefactions on man than in any other of her works. Unconsciously received, yet born of it, there is a spiritual teaching, an uplifting influence, in the study of birds which tends to make a man act more constantly from principle, which tends to give a new and a more wholesome tone to his whole life.

The companionship of birds affords a happiness as pure, perhaps, and as permanently exquisite as man in his present state of being can possibly enjoy. Never came purer joy into my life than when, rising at dawn from my couch of fern, I heard the approach of the coming day heralded by a chorus of glad bird voices. Never have I experienced emotions which have so lastingly impressed my mind as when, in the inexpressible mystery of the darkened forest, with the stars drifting over, I listened to the sublime notes of some feathered psalmist, itself in night invisible.

The world itself is but an outline sketch; it is the birds which fill in the details and complete the picture. Towered vapours of the summer firmament hang on the wall of the sky against a setting of immutable blue; the trees are motionless; the glassy waters of the lake too idle to curve and break upon the shore. Nothing speaks of life or action. Suddenly, hitherto unseen in leafy tracery, a bird rushes out and up into the air, telling the sunshine all its joy. One can almost hear the mechanism start. The world begins to live and move. What artist is there who does not know this? Even when painting either of the two most majestic scenes on the earth—the ocean or the Himalayas—he adds this stimulating power to his canvas.

To turn from the palette to the pen, what poet is there who has not been inspired by birds? From the background of my memory a thousand instances of such inspiration come leaping forth. Shelley, Coleridge, and Longfellow, to mention three only of our singers, have been each rendered immortal in virtue of the power exerted on their minds by the bird. "To a Skylark," "The Ancient Mariner," and "The Birds of Killingworth" are poems that are imperishable.

The Mexicans felt the poetry when they looked upon the humming-birds as emblems of the soul, as the Greeks regarded the butterfly, and held that the spirits of their warriors who had died in the defence of their religion were transformed into these exquisite creatures in the mansion of the sun.

Was all this beauty for no purpose but for the gratification of a passing fashion? Is man constitutionally unable to realise that in the beauty of these feathered jewels there is a value greater than the value that is entered in a ledger? Children gather flowers of the field, and, presently, their fleeting fancy sated, toss them aside to wither and die. But the seeds, the roots, remain. The daisy will bloom another year; the cowslip will stain the meadows yellow

as of yore; but these blossoms of the air will never bloom again. Once gone, they are gone for ever.

Conclusion.

Birds unquestionably are one of man's most valuable possessions, yet it is just the possession on which he sets the least value.

Wherever there are birds whose plumage is suitable for millinery, there will the cruel and rapacious agents of the feather dealers be found engaged in wasteful destruction. Wherever there are birds that are classed as "game," there hastens the market hunter to kill, so long as any saleable thing remains to be killed. Wherever there are species that have been harried by man to the brink of extinction, there will be the collector also, anxious to obtain the last lingering representatives of a race before his rival gets a chance to do so. Wherever there are birds whose eggs are valuable, there hurries the egg collector to destroy not only the embryonic life, but often the mature life as well, by shooting the bird that laid the egg for the purpose of identification. Wherever in the wild places of the earth there are birds which are considered to be "good sport," there saunters that vandal of creation, the hunter of means and leisure, to expend on the most beautiful and the most harmless works of nature his instinctive desire to kill.

It is the nature of infamies, as well as of disease whose progress is not checked, daily to grow worse; and if the present-day wasteful and depraved practice of denuding the world of one of its most valuable natural resources is not checked, there will be wrought a mischief, a universal disaster, more awful in its results than words can express.

THE PERSIAN GULF IN 1913-14.

Trade of Bushire.

As our occupation of Mesopotamia and the probability of its extension northward at no distant date is concentrating public attention more and more on the Middle East and the ports of the Gulf, the progress of the trade of Bushire is of considerable interest. The town itself is situated at the northern end of a long peninsula running parallel to the mainland and joined to it by a sandy spit, which in winter more resembles a marsh. The population of the town is estimated to be 18,000, composed chiefly of Persians and Arabs, the former of whom tend to diminish in number. The inhabitants consist almost entirely of merchants, brokers and shopkeepers, seafaring men and coolies. Most of the important merchants hold agencies for Manchester firms, while the European official and mercantile community numbers some forty persons. Bushire has neither monuments nor relics of antiquity. The narrow and tortuous passages amid the overhanging mud-houses are filthy and ill-ventilated, but a self-supporting municipal organisation is now taking shape and the sea walls were rebuilt during the year ended March, 1914, and some of the thoroughfares were lighted and a small police force instituted recently provided with uniforms, blue for the winter and khaki with red facings for the summer. The proceeds of municipal taxes are allowed to be available for local improvements, and are not appropriated by the central treasury, and if this freedom from interference by an unappreciative capital be allowed to prevail much good may be expected. There is in Bushire one school for 350 Mohammedan boys, organised on modern lines. English is taught by an Armenian educated at Calcutta, and the three upper classes spend an hour daily at the language. Other subjects taught are Persian, Arabic, arithmetic, geography, Mohammedan law and Persian history. Many of the larger Bushire firms can correspond in English; French is almost unknown. Persian is the usual medium of correspondence.

With regard to the part played by Bushire in the distribution of foreign trade, its importance lies in its situation at the terminus of the great caravan route running through the middle of Persia by way of Shiraz and Isfahan to the capital, Teheran. The prosperity of the port thus depends largely on the up-country markets, on the security of the roads, and on the available means of transport.

The Kazarun route from Bushire to Shiraz continued in use throughout the year, and though traffic was interrupted on two occasions in consequence of attacks on the gendarmerie, it was not found necessary to divert caravans to any of the alternative routes, as has from time to time been the case in the past. In January and February a strong anti-gendarmerie feeling began to manifest itself, some of the neighbouring khans were plotting against the force, and muleteers were complaining of the over-regulation of the road, and on February 26th an outbreak took place which came near destroying a considerable proportion of the gendarmerie, and from the effects of which the force will take many a long day to recover. The only Swedish officer at Kazarun was shot dead, trying to make an arrest there, whereupon the whole countryside rose and besieged the gendarmes in their barracks. On the latter being rescued, they ran amock in the town, looted indiscriminately and committed the most horrible atrocities. British firms in Bushire alone estimated their losses at Kazarun at £4,850.

As regards the volume of trade, the total imports for 1913-14 decreased by £125,953, as compared with the previous year, there being a considerable drop of 38 per cent. in the value of ordinary cotton piece goods. Specie imported

exhibited a decrease of £62,000, and the progress of the Anglo-Persian Oil Company at Mahommerah also much reduced the market for foreign kerosene. The exports also exhibit decrease, owing to the failure of the harvest.

IRISH KELP INDUSTRY.

The Twenty-second Report of the Congested Districts Board for Ireland, recently issued, gives some particulars of the Irish kelp-making industry. It appears that the rise in the price of kelp which was mentioned in the previous report has been maintained. This increase, it is stated, was necessary if the Scottish and English manufacturers of iodine and its by-products desire to procure supplies of kelp from the west of Ireland, as the price of the fused or charred seaweed known as kelp had sunk to a rate that no longer encouraged the collectors and burners of seaweed to continue to pursue one of the most laborious occupations conceivable, at which the clothes of the workers are generally soaked in sea-water or rain, or in both. The seaweed is snatched from the shore during a storm, or in some places during calm weather is torn with long rakes from the bottom of the sea where there are rocky shoals. The tearing of the seaweed from the bottom of the sea is carried out at considerable risk by crews in open boats, and a fair price is certainly due to the men and women engaged in the task. When the harvest of particular kinds of seaweed is gathered, it has to be turned and dried like hay until it is dry enough for burning in trenches dug in the ground above high-water mark. The buyers of the kelp complain, and often justly we fear, that, when the seaweed is in a molten state, sand and stones are sometimes mixed with it in order to increase its weight, as kelp is bought by the ton All real friends of the kelp-burners urge them to abandon any such method of adulteration, as the purchasers, who make a careful chemical analysis at the time of purchase, find out whether the kelp has been adulterated, and, if they find stones, gravel or sand in the clinker of burned seaweed, a lower price all round is not unnaturally fixed by them so as to protect themselves from the fraud that is uselessly attempted. A new method was tried a few years ago of burning the seaweed to ashes instead of clinker. The kelp-buyers do not, however, at most parts of the coast, wish the new method to be continued, as the ashes have to be put in bags and are more liable to injury from the weather.

AMERICAN PEARL FISHERIES.

Salt-water pearl-fishing in America has been pursued from earliest history, and while these fisheries may not be as ancient as those of Ceylon or the Persian Gulf, Columbus and his successors often found uncivilised nations of the West wearing pearls of great value. Indeed, so many pearls were found off the Venezuelan coast that early explorers gave the name of "El Gulfo de las Perlas" to the most prolific fisheries there. Nowadays Margarita Island, off the Venezuelan coast, is frequented by hundreds of boats every autumn, and the divers reaped such a harvest that the Government had to resort to special precautions to prevent the extermination of the beds. Many of the expert divers of Venezuela have engaged themselves to an Ecuadorian company which is developing pearl-fishing along the coast of that country. Near the little port of Manta the results have proved quite satisfactory, and during a recent year about £4,000 worth of pearls were shipped to European markets. Along the shores of the islands of Panama Bay there are pearl-fisheries, the exploiting of which, however, are much hampered by the heavy tides in these parts. A boy accidentally picked up an oyster a few hundred feet from the shore which yielded a pearl that brought locally £600. Later on the same pearl was sold in Paris for £2,400. It is said that, speaking generally, an ordinary fishing-boat party expects to secure several tons of shells a day, and possibly one shell in a thousand contains a pearl. The Mexican waters in which fishing takes place are from 30 to 50 ft. deep, and the expedition, which is at work for from four to six months, often costs from £2,000 to £3,000, and even if the pearls do not always pay for this outlay the mother-of-pearl, which is so highly prized for toilet articles and the like, should be of sufficient value to repay the general outfitting expenses.

It is said that pearls from American waters are to be seen in the crowns of most European rulers. One of the most valuable pearls ever obtained in Mexican fisheries was sent to Paris, and there sold to the Austrian Emperor for £2,000. On another occasion the Government of Spain presented to Napoleon III. a black Mexican pearl valued at £5,000. The combination tints of black, blue and green are quite rare, and the Mexican and Panama pearls often combine these colourings to the height of perfection. Many valuable pearls are secured by ignorant divers who, not knowing their true value, part with their finds for a mere pittance; often beautiful gems are sold for two or four pounds, only to be resold in the markets for £2,000 or £4,000.

Many of the world's most beautiful pearls have come from Venezuela, and it is said that in 1579 King Philip of Spain obtained from near Margarita Island a pearl weighing 250 carats, which was variously estimated to be worth from £8,000 to £14,000. The most perfect pearl in the world is said to be the "La Pellegrina," a rare gem preserved in the Zosima Museum in Moscow; it weighs 28 carats, is globular in form, and originally came from Indian waters. The world's largest pearl is in the Hope Collection in the Victoria and Albert Museum, which

weighs 3 oz., and has a circumference of 4½ in. According to one of the chief authorities, a pearl of the finest grade should have "a perfect skin, fine orient or delicate texture, be free from specks or flaws, and be of translucent white colour with a subdued iridescent sheen. It should be perfectly spherical, or, if not, of a symmetrical shape. White or pink pearls are the finest, owing to their delicate sheen." In China and Japan pearls are mentioned in history as early as 1,000 B.C., and nowadays a process for the artificial propagation of pearls is to be seen at a pearl farm at Argo Bay, whereby a serum is injected into the shell and, irritation being set up, the oyster is encouraged to coat the offensive foreign matter with layer after layer of calcareous deposits. A few years pass and the same oyster is fished up from the waters and his pearl-making work examined. Possibly a beautiful pearl may have been formed.

River or fresh-water pearls are found quite generally in temperate climes of the Northern Hemisphere, especially in the British isles, Saxony, Bavaria, Bohemia, Canada and in many parts of the United States. In many of the rivers of Ohio and other States mussels have been found from time to time that contained good pearls, but the general public is said to be disinclined to purchase these.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The War and Production.—The limiting effects of war make themselves more noticeable, and it is probably safe to say that the total productive powers of the British textile industries have, for the time, passed the zenith. There are sections which are not too fully employed, but those who most want men cannot find them, and the joint demands of the Army and the munitions factories forbid the idea of any material total expansion of textile work. The proximity of the limits is felt otherwise than in the direct inability to secure men. Industries rely upon each other, as manufacturers have been sharply reminded by a recent rise in coal. Costs of all supplies advance either because of the shortage of men to make them or of the exceptional demand for other purposes, and upon the whole this process seems likely to continue. Until the emergency arose nobody realised how many essentials in one sort of manufacturing are indispensable to some other, or how the rival demands might clash when there was no longer unlimited room for increasing the production of any article which chanced to be wanted. Even though the pressure is borne in good part, it is unmistakably felt, and there is perhaps to be more squeezing to fit into a narrower world. Nobody escapes the practical difficulties, which are naturally more annoying to those who are faring badly in profits than to producers who are more handsomely compensated for their troubles.

The Demands upon Machines.—The limitation of consumption began with the war, during which stocks in hand in all markets have been decreasing, while machinery has been occupied largely in making goods different from those needed for normal purposes. Eventually these reserves will have to be restored to a certain level, and until that has been reached replenishments will be wanted with more than the usual urgency. A state of affairs that on the one hand restricts production and upon the other admits of some quickening of demand, is not essentially an unfavourable one for parties in a position to produce manufactured goods. There are accordingly promises of an uncommonly good time coming for those fortunate enough to own machinery. Textile machinery is, of course, dearer than it was, and all facilities for obtaining new machines have been reduced. If new building is not absolutely out of question, there still remains the inadequacy of the labour supply. Machine-makers find that such new business as reaches them is traceable in almost all cases to war work. The circumstances seem all to point to the desirability of increasing the capacity of such machines as exist, and to favour the adoption of auxiliary labour-saving devices. The habit still persists of measuring the value of time by experience gained in days before the war, although that world-shaking event can hardly do less than require the use of a new set of standards.

The Dyeware Famine.—The want of dyestuffs remains one of the serious troubles of the manufacturer of dyed goods, and, unfortunately, not a diminishing one. As dyers' colours and the high explosives, for which there is an illimitable demand, draw upon the same raw materials and reagents, the prospects of an increased supply are not too good. Consumers have to be thankful for colours at any price, and are paying something over six shillings for dyes that sold freely at fivepence or sixpence less than twelve months ago. Reports of a prospective increase in the output of anilines have only a secondary interest to men whose wants are immediate, but their number is not without significance. It was reported lately that a Bill to provide a subsidy for manufacturing aniline and alizarine colours was being introduced in Japan, where there are at least cheap labour and commercial organisations for pressing the sale of colours throughout the East where the German companies have had a profitable business. The efforts in England, America, France and Russia, added to the enlargement of the works in Switzerland, point to at least a considerable dispersion of an industry that has hitherto been remarkably concentrated. Without anticipating events too far, it may be noted that the years immediately following the Franco-Prussian War were those in which the German colour trade found its feet. The Continental war next following has prompted more or less every nation to undo the concentration of the colour supply. In a view of the case presented in a German journal the textile

industries of the new colour-making countries are destined to suffer for their obligations towards the new colour works. Even so, the fate marked out for them is not harder than that allotted by the writer to those Germans who have to provide a home market for colour by manufacturing inland the dyed goods formerly made abroad. As colour represents at most 5 per cent. of the value of the dyed commodity the case can be summed up in a homely illustration. On our side the dog would have to wag a weighted tail, and on the German side the tail would have to swing a burdened dog.

Troubles of Marketing. - The notion that American industry was bound to profit from the disabilities laid upon manufacturers in the Old World readily gained acceptance as an axiom. The president of the American Cotton Manufacturers' Association has, however, had to admit to a disappointment. Instead of running night and day, as expected, a good many American cotton-mills are actually upon short time, and few of them are doing what can be called a profitable business. It may thus be supposed that, broadly, the same influences have operated in the United States as in our own country, for the description applies about equally to either. The effects in America have been ascribed to other causes—to defects of the American export distribution system, to ignorance of foreign wants, to faults in the American tariff, to the want of an American mercantile marine, and to the absence of general advertising devices. Improvement in some or any of these respects might have assisted Americans to make the most of their own opportunities; but it is not apparent that they would have relieved customers of their disadvantages, and the disabilities of buyers are matters deserving of being taken into serious account in any consideration of the question. Those who have been led to form an opposite impression may be astonished at the confession made by a manufacturer described as one of the best-posted in America. The confession is that "we" (meaning American cotton manufacturers and their commercial agents) "are undoubtedly the poorest merchants in the known world." How much of this self-abasement is due to chagrin over a failure to obtain business not readily obtainable by anybody, and how much to long-established conviction, does not immediately appear. It would not be easy to apportion the causes of English success in the cotton trade as between the manufacturing and the merchanting branches. The two are distinct, and there is no denying that much is due to the division of functions, the activities of merchants, and the facilities afforded by our banks. The Americans are not, however, advised to follow the Lancashire system of trading. The Assistant Professor of Marketing in the Harvard School of Business Administration recommended each manufacturer to make his own studies of the foreign field for himself. The example of a playing-card manufacturer was commended—a manufacturer who engages men to play cards with all classes of people in specific countries for weeks and months, learning the favourite games of the people, and their preferences in designs for the back of the cards, with their wish in the matter of "body" and "slip." It does not reflect upon the enterprise of those who utilise these methods to point out that the measures must come in somewhat expensive when the manufacturers in point can be numbered in thousands. Free from the responsibilities of the machine-owner, the merchant is able to devote more attention to the fluctuations of foreign fancy than the manufacturer can reasonably be expected to spare, and the merchant has the incidental facility of going further to meet incipient changes, for he can offer a wider variety of goods than any one manufacturer can economically produce.

Textile Research Work.—The devotion of new public funds to the furtherance of industrial research should stimulate manufacturers to consider the points upon which they most need illumination. Evidently it is for them to determine their needs and to press for their favourable consideration. A disposition has been noted to connect research exclusively with chemistry, and to conclude hastily that the money cannot be better applied than to the problems surrounding dyewares. Some separate provision has been made for those last, and it seems desirable to inquire whether there is nothing in the line rather of physics than chemistry, and of textile materials rather than of chemical products, deserving of special endowment. There doubtless was a time when the devotion of funds to the study of the nature of steel seemed quite as quixotic as minute attention to the small characteristics of textile fibres may seem to-day. At present there is comparatively little to go upon in the way of practical demonstration of the utility of scientific investigation applied to textile fibres and processes, but this should not constitute a barrier. The object is the discovery of that which remains unknown, and which, if known, might lead to unrecognised consequences. The whole matter being one of the finest of fine points, it follows that there may readily be disagreement as to the work that should be undertaken first. But there is probably nobody who has not encountered the inexplicable in course of his own technical work, and a recapitulation of the things one wants to know should afford a fair basis for the guidance of investigators. Every department has its own problems, to some of which more private research has been applied than to others. To take a fairly obvious and crude example, many are concerned to know the exact effects of increasing the twist in yarns. Up to a point increase of twist gives increase of strength, and beyond that point the tensile strength diminishes. So much is established by private

experience, and it is apparent that the variation, although not uniform, conforms to certain rules which are doubtless capable of elucidation by experiments conducted upon an adequate scale. In other connections there must be relatively simple facts waiting to be liberated, to the general advantage of all concerned, and it cannot be gainsaid that more revolutionary discoveries may be lying hidden and unsuspected.

CORRESPONDENCE.

DESIGN AT THE BRITISH INDUSTRIES FAIR.

In the interesting notice of the Design Exhibition in the *Journal* of the 4th inst., you comment on the absence of the work of younger and less known men, and express regret that so few are coming forward as designers. I think this may be accounted for in the first place by the limited time given the promoters of the exhibition to make it more widely known; in the second place, by the few young men who find the vocation of design production at all attractive under the present conditions of trade. Add to these two reasons the reluctance of many designers to exhibit their work to the public, and the fact that many manufacturers are slow to sanction a show of work in which is divulged the names of those on whom they rely for their "specialities." The last is a very real difficulty with promoters of exhibitions of this kind, and it will always prevent a very attractive and "up-to-date" show from the point of view of the buyer of designs and the trade decorator, resulting in something drab and *passé*.

I am fully in agreement that British design, as compared with German and Austrian, is very easily first in more ambitious decorative pattern; this is quite evident to any who know the production of the looms and printing-mills of this country, and the very large export trade we are doing in printed fabrics and wall-papers.

Now that London has firmly established a reputation for design production—although still a long way second to Paris—I am confident it will grow in importance when better co-operation is effected between Art education and trade. Industry without profit is impossible, and design apart from industry is impossible. Let us frankly admit this, and we shall make further headway.

ARTHUR WILCOCK.

NOTES ON BOOKS.

ENGINEERING. By Gordon D. Knox. London and Edinburgh: T. C. & E. C. Jack.

This book forms part of Messrs. T. C. & E. C. Jack's "Romance of Reality" series, of which four other volumes have already appeared, dealing with "The Aeroplane," "The Man-of-War," "Modern Inventions," and "Electricity."

Mr. Knox has selected, as he says, almost at random, a page here and there from the history of engineering. He begins with canal cutting, and gives an interesting account of the construction of the Duke of Bridgewater's canals and his connection with Brindley. The story of this work, with its great and often unforeseen difficulties, such the crossing of the Sale Moor Moss, makes as fascinating reading.

From the Manchester-Liverpool Canal Mr. Knox jumps to the latest and greatest of canal works. Much has been written about the Panama Canal, and the main features of it are familiar to the general reader, but in the same number of words it would be difficult to get a better description of it than is here given.

Irrigation, waterworks, and aqueducts are the subject of the fourth chapter, which includes an account of Myddelton's enterprise in constructing the "New River" in James I.'s reign, and of the building of the Assuan dam Next we have chapters on bridges, on railway construction, tunnels, mining, ships and salvage, lighthouses, docks, harbours, telegraphy, telephony, roads and materials, and a final section on engineering in war.

Without going into technical details, Mr. Knox contrives to give a very readable account of the various works which he describes, and he certainly makes out a very good case for engineering as a romantic career. It is the kind of book which, if put into the hands of a boy of a mechanical turn of mind, should inspire him with a desire for a deeper and more serious study of the subject.

THE ENGLISH COUNTRYSIDE. By Ernest Pulbrook. London: B. T. Batsford, Ltd. 7*s*. 6*d*.

Mr. Pulbrook is one of those enthusiasts for whom the English countryside has an irresistible charm. "Prehistoric trackway, ancient village, sleepy town, the farmhouse in the hollow, the sheep-fold on the hill"—all these inspire him with the passion for rambling, nor, presumably, is he above enjoying his pot of English beer at the "Chequers" or the "George" when his day's ramble is done. The result of this enthusiasm is a chatty book in which he takes us wandering haphazard from Cornwall to Cumberland, now stopping to look at a harvest scene on the Chilterns, now pausing to study the snow on a Yorkshire moor.

But pleasant as is Mr. Pulbrook's writing, he will, perhaps, hardly find fault with us if we say that the part of his book which has given us the greatest pleasure and recalled most vividly those nooks of England in which he rejoices, is the illustrations. With one exception these are photographs; some are from the author's own camera, but the majority are from the well-known series of Messrs. F. Frith and Co. of Reigate. It would be difficult to give some of these pictures more praise

than they deserve, and the manner of their reproduction leaves nothing to be desired. On more than one occasion we have felt called upon to compliment Messrs. B. T. Batsford on their share in the books which they publish. This volume is, in its way, as good as anything they have done, and as a piece of book-making is a thoroughly artistic production of which any firm might be proud.

GENERAL NOTES.

Egret and Heron Rearing in Madagascar. - An article in the *Bulletin Économique de Madagascar* gives an account of the domestication of herons and egrets in that island, whereby it has been found possible to obtain the plumage of these birds without any of that horrible cruelty which has come to be associated with the plume hunters. In the Vohemar province egrets and herons are reared and tamed by the natives, who keep them merely as pets and without an eye to profit. They are turned out by day to seek their food in the marshes or from the ticks and parasites of the cattle, and return home to roost at night. The plumes begin to appear when the bird is about six months old, but they should not be taken until it is sixteen months, or perhaps not until it has produced its first brood. They are finest at breeding-time, and are cast after this to appear next year. They should be taken by cutting near the base, and the stumps should be removed later, when they have dried up. The time to cut them is when the young begin to leave the nest and feed themselves. The article contains information as to the treatment and feeding of the birds. There are considerable difficulties in managing them—for one thing, strange birds are apt to fight furiously with one another, even to the death—but the plumage, if in good condition, is so valuable that it might well pay to start the domestication of the birds on a considerable scale.

Indian Indigo.—The contribution of Mr Howard, the Imperial Economic Botanist, to the annual report of the Board of Scientific Advice for India, contains a ray of hope for the indigo planter. The Sirsiah experiment station was closed in 1913 because the selection work on Java indigo could not be satisfactorily conducted there, owing to the fact that the plant could not be induced to form seed. The non-success of the experiments was due to "wilt," which was also the means of reducing the area under the Java plant in Bihar from 70,000 bighas in 1910 to 15,000 bighas in 1913. The botanical section at Pusa has now,' however, discovered the cause of the "wilt," which is the product of the long continued, constantly wet condition of the soil. It seems that if Java indigo is sown for seed early in August on well drained land in good condition, the disease is avoided and good crops of well developed seed are produced in February. The indigo plants can be again cut for leaf the following monsoon. These results have been repeated, Mr. Howard says, under estate conditions, and one of the chief causes of the decline in the area under Java indigo has been removed. The success of other experiments made at Pusa leads Mr. Howard to add "that the future of the indigo industry is by no means so hopeless as is often believed."—*Statesman*.

The Onion.—The larger Spanish onions are brought from France to England by boat, and are hawked throughout our South coast towns by the boat-people. It is probable that the French supply will be needed for their own use. The smaller wild species of *Allium* have been eradicated from the dairy pastures of the Midlands by the English farmer. In the botanic garden of Oxford the European and Asiatic species may be seen, and some twenty years since the cultivation of the onion was largely improved at Banbury in Oxfordshire and at Rousham. The repute of the kinds is yet maintained, but the cultivation does not get beyond that of the market garden. In an old edition of the "Encyclopædia Britannica" it is stated that the Arabs and inhabitants of the arid parts of the East use the onion for rubbing the lips and nostrils to protect them from the sun when exposure to the day's heat is necessary. The troops employed on duty in the East may find a native custom to be worth following.

Exhibition of German Trade Catalogues. The importance attached by German manufacturers to the production of catalogues printed in the language and currency of the country to which their goods were exported is well known, and has frequently been emphasised in the reports of His Majesty's Trade Commissioners and Consular Officers. In order that British manufacturers may have an opportunity of inspecting catalogues of German origin, the Board of Trade have collected over 700 specimens, illustrating a great variety of industries, and these may be inspected at the Foreign Samples Section of the Commercial Intelligence Branch, 32, Cheapside, E.C. In a number of cases goods similar to those illustrated in the catalogues are on view in the adjoining sample rooms.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 21.. Victoria Institute, Central Hall, Westminster, S.W. Annual Address by Professor E. Naville, "The Unity of Genesis."

British Architects, Royal Institute of, 9, Conduit-street, W., 8.30 p.m. Presentation of the Royal Gold Medal.

Thursday, June 24...Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Friday, June 25...Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Journal of the Royal Society of Arts.

No. 3,266. VOL. LXIII.

FRIDAY, JUNE 25, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

FINANCIAL STATEMENT FOR 1914-15.

The following statement is published in this week's *Journal* in accordance with Sec. 40 of the Society's By-laws:—

TREASURERS' STATEMENT OF RECEIPTS AND PAYMENTS FOR THE YEAR ENDING MAY 31st, 1915.

Society's House, Adelphi, 23rd June, 1915.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Sixty-first Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new Fellows, will be held, in accordance with the By-laws, on Wednesday, June 30th, at 4 p.m.

(By order of the Council),
HENRY TRUEMAN WOOD, *Secretary.*

SPECIAL WAR LECTURES.

The Council have arranged with Professor Vivian B. Lewes to give a short course of special lectures during the recess on "Modern Munitions of War." Three lectures will be given at 4.30 p.m. on Wednesday afternoons, July 7th, 14th, and 21st.

The first lecture will deal with "Guns and Propellants," the second with "Mines, Shells, and High Explosives," and the third with "Poison Gases and Incendiary Bombs." The course will be given under the Fothergill Trust.

The lectures will be open to all Fellows of the Society, who can admit their friends personally, or by the usual tickets. Any Fellows requiring further tickets can apply to the Secretary, who will furnish them with any number they may desire for distribution. Tickets will also be issued gratuitously to any persons interested in the subject who may apply to the Secretary.

BRITISH MALAYA.

ENGINEERING AND GENERAL TRADE POSITION AND PROSPECTS.

By GEORGE D'ALMEIDA,
Portuguese Consul in Singapore.

A region receiving considerable attention from manufacturers and commercial men prior to the outbreak of the war was Malaya, particularly that portion which is under the aegis of the British flag, and it is not a fanciful deduction that when the nations return to sanity and men are turning their swords into ploughshares, Malaya

will receive much more attention than it has done in the past. The potentialities of China are greater, for it is a large country with a huge population; but it lacks the stimulus that British officialdom has given to private enterprise in the southern Settlements and Protectorates, and has not shown the same rapid movement towards self-development. It rejoices the heart of the engineer to see the measures adopted to develop British Malaya. The dock improvements at Singapore have converted that port into a first-class *entrepôt* as well as a naval base, and its position on the ocean highway between Europe and China ensures to it permanency and further development. Already an important terminus of the Malayan railway system, its harbour facilities will be enhanced when the bridge is constructed across the Straits of Johore. At Penang and Port Swettenham improvements are in progress, all making for the rapid transit of goods inward and outward, and the transhipment of cargo from local vessels to the ocean leviathans that make these places ports of call. In the interior the administration of the Federated Malay States has made improvements of incalculable value for the future of the country. The railway system compares favourably with any in the world, and is being extended to open up new areas throughout the whole of the Peninsula. The road system has won the highest encomiums, the best proof of their quality and condition, perhaps, being the steady increase in the import of motor-cars and vehicles. Public buildings and public works of every description tend to make life in the interior more attractive to native and European alike, while the expansion of the two main industries—tin-mining and rubber-planting—has added materially to the wealth of the country and the prosperity of its inhabitants. The total amount spent on public works in 1913 was £1,145,509, and in five years over four and a half millions sterling were expended. For 1914 the Federal estimates provided for an expenditure of £2,839,809 on railways against £2,168,966 in 1913.

Great Expansion of Trade.

In 1913 the Federated Malay States absorbed machinery to the value of £340,113, and railway and tramway materials valued at £324,882. In the case of machinery, the increase over the value for 1912 was £112,200, while in the case of railway and tramway materials there was an increase of £233,248. In four years the value of the trade of the Malay States almost doubled itself, the aggregate for 1913 being £27,425,843, against £14,287,936 in 1909. The increase in the import of manufactured articles was nearly 40 per cent. over 1912, the increase under this head accounting for over 75 per cent. of the total increase in imports.

Prospects for Machinery.

It is not to be wondered at that the prospects of machinery are very good, when consideration is given to the necessities of the new rubber plantation factories, the growing use of machinery in mining, and the spread generally in the use of mechanical appliances wherever they can compete successfully against the cheap native labour. For instance, the total horse-power of steam, gas, oil, hydraulic, and electrical plant employed in mining in 1913 was estimated at 25,756, compared with 23,188 in 1912. The following statistics from the Federated Malay States should have a special interest to our readers, as they show the value of some of the principal manufactured articles imported and the increase in round figures over 1912:—

	Value.	Increase
Ironware	£363,517	£149,100
Machinery	340,113	112,200
Railway and tramway materials	324,882	233,200
Cycles, motor-cars, and accessories	237,610	52,970
Cement	91,661	35,470
Steel	68,108	49,930
Telegraph and telephone materials	67,753	42,460
Tools, instruments and implements	59,974	17,200
Corrugated iron	57,877	25,300
Gas and electric lighting materials	34,375	10,090

There are many branches of trade where British manufacturers could improve their position in Malaya at the expense of some of our pre-war competitors, but few in which those enemy countries hold the superiority in the aggregate amount of trade done. Most of these, however, lie outside the scope of this article. The moral that might be drawn from an investigation of the official statistics issued by the Straits Settlements Government is that both Germany and Austria-Hungary have been represented in Malaya by energetic and far-

seeing agents, who have missed no opportunity of securing a footing and fostering and developing whatever business connection they succeeded in establishing. An idea of the relative positions of the trade of the United Kingdom and Germany in Malaya may be gathered from the following statistics taken almost at random:—

	1912.	1913.
Ironware (excluding Cooking Utensils, which come chiefly from Austria-Hungary).		
United Kingdom	£198,583	£269,782
Germany	16,895	20,883
Machinery—Electrical.		
United Kingdom	32,160	58,415
Germany	9,109	9,474
Machinery—Miscellaneous.		
United Kingdom	81,753	127,763
Germany	6,262	8,068
Cycles, Motor-cars, and Accessories.		
United Kingdom	143,935	153,756
Germany	11,125	4,831
Tools, Instruments, and Implements.		
United Kingdom	46,123	95,163
Germany	3,381	4,590

The railway and telephone and telegraph materials imported by the Government come almost exclusively from England. Statistics, though perhaps less attractive, are more satisfying than rhetoric to the business man, and if this short article has convinced our readers of the growing importance of British Malaya as a field for articles of purely British manufacture, its object will have been accomplished. Recent years have seen great changes in the Malay Peninsula. Greater changes are unquestionably in store, for the way is being prepared by the engineer for the development of this tropical Protectorate as one of the richest portions of the British Empire. Manifestly, it remains with the manufacturers and the man of commerce (backed up at all times by the press of the entire country) to ensure that British trade and commerce shall hold supreme sway in this region.

PROSPECTING FOR OIL AND GAS IN NORTH AMERICA.

By Chas. N. Gould.

In the early history of the petroleum and natural gas industry in North America there was very little done in the way of scientific investigation as to the most likely places at which to drill for these products. For many years those engaged in the oil industry had no knowledge of any relationship between the structure of the rocks and the accumulation of oil and gas. Some twenty years ago, however, geologists began studying the structure of the oil-fields, with the idea of finding out whether it might be possible to determine, in advance of drilling, where oil was most likely to occur. During the past twenty years many scientists, both in Europe and America, have studied this problem, until at the present time petroleum geology is a recognised branch of the science of geology, and the subject is taught in many of the larger universities.

The geologist's methods of work are not always understood, but they are perfectly plain and simple. They include, chiefly, good eyesight, good judgment, and years of experience. In attempting to outline these methods, and to show how the geologist goes about his work, I must first sketch very briefly the conditions under which oil and gas are found.

Long experience in many lands has shown that, in order that oil and gas should occur in paying quantities in any particular region, at least four things are necessary: a source of supply, a reservoir rock, a cap rock, and some form of structure which will hold the oil.

Whatever be the origin of oil or gas (and no one knows to a certainty how these substances have been formed), there must be some source of supply, some rock in which the oil and gas have originated. Experience has shown that the source of supply is usually a ledge of limestone. Many of the largest oil-fields in the world obtain their supply either directly from heavy limestones, or within a short distance above such formations.

A reservoir rock is also necessary in order to contain the oil. In the oil-driller's parlance this reservoir rock is called an "oil sand," because it is usually a porous sandstone, which has been filled with oil. In some cases, however, the reservoir rock is a limestone, as, for instance, the Trenton limestone of Ohio and Indiana, and the Tamasopa limestone of Mexico. The Wheeler "sand," of the noted Cushing field of Oklahoma, is a limestone. In many pools of the mid-Continent field, oil and gas have been found in or near the top of the "Mississippi lime."

A cap rock is a third essential, for there must be some substance to hold the oil and gas down and prevent their escaping. This cap rock is sometimes a hard, brittle limestone, or dolomite, as, for instance, the dolomite above the oil sand at Beaumont. Usually, however, it is a soft, fine-grained clay or shale impervious to liquids, which prevents these substances from escaping.

The fourth essential, and the one in which the oil geologist is particularly concerned, is some form of structure which will cause the oil and gas to accumulate in a certain region. Oil and gas are volatile substances and tend to rise in the rocks and to escape to the surface. If there is any way by which they can pass upward through the rocks, either along a bedding-plane or along a crevice or fault, they will do so, and will soon be dissipated into the air. If they cannot escape to the surface they will at least find their way to the highest point of the rocks in which they are contained, and will there accumulate.

Geologists, then, in prospecting for new oil and gas fields, look for high places in the rocks. The name given to an arch or upfold in the rocks is "anticline." An anticline is a place where the rocks have been folded up in an arch something like the waves of the sea. The corresponding downfold or trough is called a "syncline." An anticline may be of almost any length or width. A short oval-shaped anticline is usually known as a dome.

An anticline is not necessary for the accumulation of oil and gas, for any form of geological structure which will cause a high place in the rocks may form a suitable reservoir to hold these substances. In the California fields, and many other parts of the world, oil and gas are found alongside fault lines, at places where rocks have slipped up on one side and down on the other. In Mexico oil accumulates at places where the rocks have been raised by intrusions of basalt. On the gulf coastal plains of Texas and Louisiana, the oil occurs under what the geologist knows as "salt domes," places where the rocks have been raised up something like a great blister on the surface.

The form of structure is not essential, but the thing necessary is that at some places the rocks must have been elevated higher than at surrounding points. The oil and gas will then flow to the highest point of the uplift, where they may be reached with the drill.

What the geologist tries to do then is to locate the high points in the rocks, and to keep the oil-man from drilling on the low places, knowing that if he does so he will probably get nothing but salt water.

For many years geology was not in good repute among the oil-men. Twenty-five years ago they had never heard of it. Ten years ago there were not a dozen active professional oil geologists in the United States, and even to-day there are many of the old-time oil-men who learned the business before oil geology was invented, and have no use whatever for geologists. Within the last three years, however, there has been a marked change of public opinion on the subject among oil-men. The words anticline, syncline, arch, dome, dip, strike, fault and axis, all good geological terms, have become part of the vocabulary of the oil-man.

All the larger oil companies now employ geologists and have a geological department, just as they have a leasing or operating department. The methods pursued by these larger companies in locating new territory are something as follows: At least five preliminary steps are taken before any drilling whatever is done. First, reconnaissance; second, leasing; third, surveying; fourth, preparing a map; and, fifth, locating the wells. Whenever one of the larger oil companies desires to open up an untried field, the first step will be to send a corps of geologists to scout out the region. Sometimes these men are on the regular staff of the company, sometimes they are professional men who are employed for this particular work alone.

This first scouting is known as a reconnaissance. The geologist travels across the country, on foot or on horseback, sometimes in a buggy, or it may be in an automobile, carrying with him his aneroid barometer and hand-level. With these instruments he takes careful observations on the outcrops of all the ledges he can find, comparing the dip, strike, and elevation of the various formations, in the endeavour to locate what, to his mind, may be an anticline or a dome. This work is often done rather rapidly, and he can frequently cover several square miles in a single day. He may spend weeks or months in a region without finding any indications that look good.

The second step consists in leasing the land. If, as the result of scouting, the geologist is able to find a locality that shows sufficient evidence of containing an anticline to justify spending more money, he so reports to the company. The lease-men are then sent into the field, and they secure, on as favourable terms as possible, as much property as may be in the area which the geologist has recommended.

The third step consists in surveying the area and running exact levels on it. Men with surveying instruments, known as alidades, go into the region, and often spend several weeks in tracing out the various formations and plotting them on field maps. This work is done slowly and carefully, and the surveyor may often spend several days on a single square mile.

The fourth step consists in preparing the map. The surveyor goes into the office and transfers to a tracing the results of his field work, showing the outcrops and elevations of the various ledges of rock on the area examined. The object of this work is to attempt to locate, as nearly as possible, the exact axis or high point of the anticline.

This preliminary work having been done, the next step is to locate the wells. The head geologist will go carefully over the map with the manager of the company, and they together will select the most favourable site at which to drill the first well. Usually this will be very near the high point or axis of the anticline. The experience has been that, by drilling at this high point, one will be most likely to encounter gas. If gas is found in the first well on the axis, the next one will be drilled down the slope of the anticline several hundred feet away from the axis, with the hope of finding oil. In some cases it is necessary to drill three or four wells before oil is finally encountered.

The question is asked, What percentage of wells so located are successful? There are no absolute data in the matter, and for that reason the question cannot be answered accurately. The best estimates available, however, would indicate that of the wells located without geological investigation not more than five per cent. are successful, while of the wells located by geologists as the result of

careful reconnaissance and alidade work, about 65 per cent. yield fine oil or gas. Not all of these, however, find these products in paying quantities, because there are certain things which neither the geologist nor any other man can tell from the surface.

For instance, the geologist cannot be absolutely sure that reservoir sands, capable of storing oil, will be found in drilling, neither can he be sure that these sands, if found, will produce oil or gas. All that he can do is to attempt to keep the oil-man away from the improbable or impossible places, and give him a fair chance for getting back his money. In other words, there is always a risk to be taken in drilling for oil, and it is the work of the geologist to minimise the risk.

ELEPHANT CATCHING: THE PIT METHOD.

It is rather a puzzle to the general public how such a huge animal as the elephant is caught in a pit. The questions arise: How is he got out of it? How does he escape getting hurt? When out of the pit, how is he tied up, etc.? It is with the object of explaining how elephants are caught and trained that this sketch is written. In Mysore, and in other places where there are large herds of elephants and where the configuration of the country permits it, elephants are captured according to the kheddah system. In the Native State of Travancore the kheddah system was once tried in a small way and abandoned as being too expensive and difficult, as the nature of the undulating country is not suited to successful driving, without which the capture in a kheddah enclosure is more or less unprofitable. The pit system obtains in Travancore, and if the divisional forest officer is keenly interested in animals, and exercises careful supervision, this method of catching the elephant is not only successful, but does not harm the animals. The least carelessness in the arrangements often results in an elephant breaking his neck or otherwise injuring himself badly. The hot weather is the elephant-catching season, for elephants leave the higher ranges of the hills and come down to the rivers, the sides of which they haunt for the luxury of bathing, of which they are very fond. After the monsoon is well over, the vegetation affords succulent nourishment, and the *Eta* reed (*Beesha Travancorica*), (*Beesha Rheedii*), the bastard sago palm (*Caryota urens*), the bamboo, and other forest growth which elephants delight in, are in vigorous edible condition, and furnish abundant food.

A little experience tells the forest officer where the animals most do congregate, and the pits, three in a bunch, leach-bite fashion, are placed adjacent to the paths which elephants make for themselves, and which they follow invariably year after year. As little disturbance as possible is made in digging the pits, which are of one uniform dimension more or less. Some officers make them a foot or two deeper, some a foot or two less in diameter than others, but the pits are so constructed as to receive a full-grown elephant. The usual dimensions are 12 ft. deep by, say, 10 ft. to 12 ft. in diameter, gradually, very gradually, narrowing down to the bottom. The earth from the pits is carried and deposited not far away—and elephants love to throw loose earth over their bodies to keep off flies—and a very light framework of plaited split reeds is placed over the pits, over which are thrown leaves, a light layer of earth, and again dry leaves, etc., till the most practised eye is unable to tell the difference between the soil over the pits and that of the surrounding ground. Before this is done, however, the bottom of the pit, to quite one-third, is filled loosely with leaves, shrubs, and ferns to break the fall of the heavy brute. Fifty or sixty pits, new and old, are thus prepared in a range, and watchers are appointed, whose duty it is to sneak about the place and report immediately the fact of an elephant falling into a pit. All preparations have, of course, to be made safely to house captured elephants in what is fitly termed a cage. This is constructed of roughly-squared teak, or thembavu logs—teak for preference—as uprights, with solid crossbars connecting them. Uprights of the same kind divide the partitions, generally six, in each cage, with movable bars, which, when drawn, allow of the elephants being moved from one partition to another and also give them entry. The roof is lofty and is covered with a thatch of cocoanut leaves, and the floor is paved with teak planks firmly fixed and well drained.

As soon as the falling of an elephant into a pit is reported, the special officer appointed for the purpose hastens to the scene, and with him go a number of axemen, coolies with ropes and cables, and a couple of mahouts on two big and strong decoy elephants. On arrival some small trees are cut down and their trunks are laid across the mouth of the pit, and an estimate is formed of the age of the animal captured. If above forty years of age he is liberated, as it is difficult to train him. If under that age the animal is allowed to stay a day or two in the pit, and is fed very scantily, and on putting up his trunk through the interstices of the logs water is poured down, which the animal sucks down with his trunk and pours down his throat. When the animal is more quiet and does not fear the near approach of man—elephants are very sagacious and quickly recognise that no harm is intended them—a few of the logs over the pit are drawn away, and the mahouts let slip-knots down into the pit, and secure each hind leg in a noose. The noose of a small rope gives way to the noose of a cable, and the two cables are tied to trees near the pit. The whole of the cross logs are then removed, the decoy elephants are brought near the pit, and earth and brushwood are thrown into the pit, which, as they increase in height, permits of the elephant gradually

approaching the surface. On rising to the ground above, the decoy elephants close in and hem in their wild companion, and with their assistance a strong rope is quickly passed round the elephant's neck while the leg cables are tightened by a lot of coolies. The wild creature struggles at first, but the decoys do not spare him and punish and show him his limitations, and after a while the captive submits and is hauled along by his companions, any sudden effort being checked by the coolies hanging on to his leg ropes and the decoys.

It is extraordinary how soon the newly-captured creature understands that if he goes quietly along all will be well with him, and as the cage is not far off he is soon taken to the sliding bars, which are withdrawn, and he is finally shoved into his partition with a last butt from the decoy. The partition is so built as not to give the elephant room enough for a charge, though there is ample room for him to turn round and move about comfortably. The animal at first makes a rush or two, and only hurts himself, while the coolies outside shout and try to make him desist. After a little experience of this kind he becomes quiet, and is always ready to grasp at a bit of succulent food. There are wooden troughs in the partitions filled with water. Of course, as soon as the elephant is about to enter the cage the leg cables and neck ropes are removed. These ropes often cause abrasions difficult to heal, as remedies cannot be applied without danger to the mahout. Big syringes with carbolic lotion and medicated oil are used, and help to keep the wound healthy till the mahout is able to venture into the cage. I have known young elephants who became amenable to the mahout's attentions after twelve or fifteen days, while others remained recalcitrant for a month or forty-five days. There is a type of elephant with broad intelligent head formation which soon submits to discipline. A narrow build of head denotes a stubborn unintelligent brute that long resists the mahout.

After a month or two the elephant is taken out of the cage, and in six months' time he learns the words of command and is dragging timber, lies down in the river to be scrubbed and bathed, or takes a coconut from his Divisional Officer by opening his mouth, and then raises his trunk and trumpets a salaam like any old stager. It is exciting work, and I once had about ten elephants newly caught in the cage together, with a cow elephant which gave birth prematurely to a calf. The little one was too small to reach his mother, and was fed with cow's milk, but did not survive long.—"*A.P.S.*" *in the Madras Weekly Mail.*

BRITISH EAST AFRICA PRODUCE.

Some interesting details regarding the produce of the East Africa Protectorate are contained in the annual report by Mr. F. W. Major, the Chief of Customs of the Protectorate, dealing with the financial year ended March 31st, 1914.

During the year under report the revenue from duties on domestic exports amounted to £15,956, of which hides and skins yielded £13,350; ivory, £1,300; and rubber, £400. The total shows an improvement of £3,000 over the previous year's collection.

The total value of the exports of domestic produce from British East Africa amounted to £443,624, showing an increase of £22,540, or 5 per cent. over the previous year. Of this total £265,904, or 60 per cent., was due to two items—viz., hides and skins, £147,474; and grain, £118,430. Next in order of importance were copra, £35,587; coffee, £18,502; fibre, £16,608; live animals, rubber (wild and plantation), wool, ivory, and potatoes.

Hides and Skins.—The trade in hides and skins is one which has held an important place in East African commerce for the last four years. In that period the value of the exports has risen from £62,258 to £147,474, the increase in 1913–14 over the previous year being £59,801, or 68 per cent. High prices prevailed during the year under report, and in the local market there were ready buyers. The largest purchaser of hides was the United Kingdom, which bought 13,363 cwt., valued at £62,884. The chief customer for skins was the United States, which purchased 4,953 cwt., valued at £17,724, the next best customer being France.

Grain and Oil Seeds.—The second largest item of export is under the head of grain and oil seeds. There was a falling-off in this trade during the year of 61,462 cwt. in quantity and £28,959 in value. As British East Africa is distinctly a grain-producing country, and as rapid strides were being made in the production of maize for export, the decline in this trade proved a great disappointment, the falling-off being due to smaller shipments of almost every item of native produce. It is hoped, however, that the deficit will be met before long by an increase in the output from European farms.

Copra.—The exports of copra (31,725 cwt.) failed to reach the high level of quantity of 1910–11, but a substantial rise in the average price has increased the value to a figure not hitherto recorded. The figures for the past four years show that the exportable surplus has remained stationary, in spite of new areas coming into bearing. This points to growing local consumption. Copra is largely used in the production of vegetable butter, the manufacture of which, it is reasonable to expect, will increase. France, as usual, took the bulk of the copra exported.

Coffee.—There was a highly satisfactory increase in the export of coffee—viz., from 2,469 cwt., valued at £7,431, to 5,501 cwt., valued at £18,502. The figures show an increase of 130 per cent. in quantity and 149 per cent. in value. The United Kingdom was easily the chief buyer of East African coffee, taking

4,190 cwts. The quality of coffee grown in British East Africa is increasing in favour in European markets, and the price obtained places locally-grown coffee among the best produced in any part of the world. The industry should prosper under ordinary conditions, but the lack of labour and the presence of leaf fungus cause a certain amount of anxiety to settlers.

Fibre.—Exports of fibre have increased from 11,848 cwt., valued at £8,150, in 1912-13, to 28,478 cwt., valued at £16,608, in 1913-14. The fibre industry was entirely initiated by European settlers. Preliminary trying difficulties have been most successfully met, and it has at last been brought to a stage which leaves no doubt as to its early future prominence in the export trade of the Protectorate.

Rubber.—Shipments of rubber amounted to 1,165 cwt., of a value of £10,532. As compared with the preceding year, the quantity receded from 1,528 cwt. to 1,165 cwt., which figure includes 687 cwt. of plantation rubber. The net export of wild rubber was, therefore, 478 cwt. only, the lowest figure on record.

Wool.—The exports of wool increased from 1,689 cwt., valued at £7,908, in 1912-13, to 2,082 cwt., valued at £9,718, in 1913-14; 2,039 cwt. were consigned to the United Kingdom. The prices realised at the London Wool Exchange sale were satisfactory, and compare very favourably with those realised for wool from other parts of the world.

Ivory.—Up to the year 1903 ivory was the staple export from the country, but it has now dwindled down to a mere trifle. Ivory shipments during the year amounted to 132 cwt., valued at £8,764, as compared with 678 cwt., valued at £24,039, a decade ago.

Bark.—Shipments of mangrove bark amounted to 8,062 tons, as against 6,774 tons in the preceding year, thus showing an increase of 1,288 tons, or about 19 per cent. The value has risen from £6,433 to £8,062.

Germany bought 5,168 tons, followed by the United Kingdom with 1,500 tons; and France, with 1,370 tons. Wattle bark exported during the year amounted to 202 tons, valued at £1,917; this is an improvement of 151 tons, valued at £1,408. One hundred and twenty-one tons were shipped to Germany, and 80 tons to the United Kingdom. The Chief of Customs is informed that over 10,000 acres of land have been planted with wattle.

Cotton.—Contrary to expectations, cotton exports receded from 2,636 cwt. to 1,204 cwt. during the year under review. The cause was unfavourable climatic conditions. As usual, the United Kingdom was the largest buyer of British East Africa cotton, and received 1,117 cwt. The growing of cotton has not proved so successful in the East Africa Protectorate as in Uganda, but strenuous efforts are now being made on the banks of the Juba River to improve matters by means of irrigation.

New Products.—Noteworthy new features were the shipments of 14 cwt. of mica, valued at £219; 21 cwt. of raw silk, valued at £60; and 9 gallons of lemon-grass oil, valued at £2, all of which were consigned to the United Kingdom. For the first time there was an export of tobacco, weighing 9,133 lb., valued at £154; 3,892 lb. were shipped to Italian East Africa; 2,330 lb. to Zanzibar, and a consignment of 2,630 lb. went to the United Kingdom. Tobacco culture in East Africa is in its infancy, but it is hoped that favourable results may be obtained in course of time. The Director of Agriculture is of opinion that there is a future for this industry in certain parts of the country yet undeveloped.

Miscellaneous.—Items of export, such as beeswax, carbonate of soda, coconuts, gum copal, horns, ostrich feathers, hippo teeth, wood, etc., amount to £30,015, showing a total increase of £2,938 over the previous year. Others, such as chillies, ghee, oil-cake, cotton-seed, fine wood, cowries and other shells, give a total export of £7,188, as against £14,727 in the previous year. These increases and decreases are of minor importance, and may be attributed to fluctuations in trade.

OIL TANK-SHIPS.

In the course of a paper recently read before the Institution of Petroleum Technologists, Mr. H. Barringer gave some interesting details of the evolution of the oil tank-ship. Although there is no written history of the earliest bulk oil-carrier, the Chinese Newchwang junk, originally built for the carriage of water in bulk, and afterwards used for oil, must be amongst the earliest examples of this class of vessel. The Chinese junk was provided with an expansion-trunk, the object of this, as in the modern steamer, being to allow for expansion of oil by rise of temperature, and also to keep the main hold always full, the wash of oil from the movement of the vessel being confined to a limited space about a third of the beam.

At the same time there is a record that special instructions were issued as to the carriage of oil up the Volga about the year 1723, and in 1754 the Persians collected oil on Holy Island (near Baku) and conveyed it in sailing vessels, evidently in bulk, as it is mentioned that the sea was sometimes covered with oil for leagues, owing to the leaky state of the vessels. It is curious to note that in the early days wooden barges were employed on the Volga to carry oil in bulk direct to the skin of the vessel, but great difficulty was experienced in keeping these tight, and considerable losses from leakage were experienced. An interesting method, adopted to reduce this loss, consisted in loading the barges when full of oil with a deck-load of stones. This gave the barge a greater draught, and thereby

caused the pressure of water outside to be greater than the pressure of oil inside, the balance of pressure being in favour of water entering the barge, instead of oil leaking out, and as the decks were kept low and the hatches were made oil-tight, this did not allow much water to enter.

Although these earlier examples of bulk-oil carriage are mentioned, it was in 1875 that the first organised attempt to transport petroleum in bulk without the use of tanks was made by Nobel on the Caspian: he appears to have loaded a wooden barge with residuum, and despatched it from Baku to Astrakhan. The venture was successful, the leakage being much less than was expected, and the saving in time of loading and discharge was an immense advantage gained. But it was not until 1878 that the first steamship, the "Zoroaster," was adapted for carrying oil in bulk: at first tanks were fitted in the holds, but later on these were removed, and the oil carried to the skin of the ship.

For some years ships carrying 6,000 to 7,000 tons were favoured, but lately the tendency has been to build larger vessels; in 1912 to 1914 the average was about 9,000 to 10,000 tons, although ten vessels each of 15,000 tons capacity were built. There are now about 434 bulk-oil, ocean-going steamers afloat, representing a total tonnage of 1,637,000. Of these vessels, 192 are fitted for burning liquid fuel. In addition to these there are fifty-seven sailing ships representing 99,788 gross tons. Many of the recent ships are on the Isherwood principle of longitudinal framing.

THE COCONUT INDUSTRY.

The Canadian Department of Trade and Commerce has received from H.M. Consul-General at Rio de Janeiro a copy of a memorandum which he has prepared respecting the coconut industry, with particular reference to Brazil. The information given in the following extracts from the memorandum is of interest as indicating the many uses and the diversified nature of the products of the coconut palm, which are rapidly assuming an important place among trade products.

The Coconut Tree.

The coconut tree (*Coco Nucifera*) is indigenous to the warmer regions of both hemispheres. The tree pertains to the palm family. Opinions are divided as to the origin of the cocoa palm, some botanists holding that Asia is the original habitat thereof, other authorities (and they are in a majority) holding that the origin of the tree is South America.

In Brazil the coconut palm attains a height of 25 to 26 metres. The roots form a voluminous mass, conical in shape, composed of short, tough fibres. The bark is grey in colour. The foliage consists of fifteen to twenty digitated leaves, from 3 to 5 metres in length, and about one metre in width.

The Fruit.

When young the coconut furnishes a delicious and healthy beverage known as coconut water-milk. The pulp of the mature nut is used for various culinary purposes, and for confectionery. The exportation of fresh coconuts from Brazil is but small in amount, since the supply has heretofore been sufficient only for local demand.

Copra.

Copra is the most important product of the coconut palm; it is in world-wide demand, and it constitutes the principal source of wealth for certain countries.

The preparation of copra is very simple. The ripe nut is split open with an axe, and the contained pulp is removed by means of a knife. There exist mechanical appliances for cracking the nuts and extracting the "meat," but the axe and the knife continue to be the most practicable implements for such purpose.

The pulp, after having been removed from the shell, is set to dry, either in the sun or in specially contrived ovens. The sun-drying process occupies some three days, whereas the furnace effects its purpose in one day.

Rain and damp must be avoided, since copra while still soft becomes rapidly mildewed, and as a result loses much of its value.

Copra lends itself admirably to the manufacture of vegetable butter. In that connection the utmost cleanliness must be observed in preparing the copra, since the whiter the article the higher the price realised.

In order to obtain good quality copra the nuts selected must be fully matured. The copra yielded by young trees is much less rich than that yielded by trees from fifteen to thirty years of age. Those latter yield, on an average, from 200 to 300 grammes of copra per tree. Thus, in order to obtain one ton (metric) of copra, the product of from 5,000 to 6,000 trees is required.

Copra serves many industrial uses, such as manufacture of margarine, stearine, soap, etc.

Germany alone imported annually copra to the value of some four millions sterling. The market value of copra in Europe averages some £30 sterling per ton.

Coconut Flour.

Coconut flour is obtained from fresh copra by means similar to those adopted in the case of manioc. The copra is first ground, and afterwards placed in a pan of galvanised iron heated to a certain temperature. The flour is kept constantly stirred and sugar is gradually added, in the proportion of 10 kilogrammes of sugar to 30 kilogrammes of copra flour. The resultant product is of very agreeable flavour, and is much used for culinary purposes.

Coconut Oil.

Sun-dried copra contains 55 per cent. of oil; the furnace-dried copra contains from 60 to 65 per cent. of oil. The average yield of oil is from 4 to

6 kilogrammes per tree. Extraction of the oil is effected by means of presses, either mechanical or hand-worked.

BAGGASE.

The residue of copra, after the oil has been expressed from same, constitutes what is known as "baggase." The product in question serves principally for cattle food, and it is an excellent aliment. The average yield of baggase is from three to five kilogrammes per tree.

COIR.

The fibrous mesocarp of the coconut is known as "coir." The manufacture of coir is of simple nature and does not entail the employment of complicated or expensive apparatus.

The manufacture of coir rope is effected in the following manner: A stout knife is set in the earth, point upwards. The operator, seated, seizes the coconut in both hands and passes it four or five times longitudinally—across the point of the knife, thus stripping off the tough fibrous covering of the nut. The fibre is then strongly beaten, twisted, and cut so as to free it from foreign matter. The fibre is then ready for being made into rope, brushes, matting, and various woven materials.

One kilogramme of coir is obtained from some fourteen coconuts.

The price of coconut fibre on the London market averages some £30 sterling per ton for best quality. For inferior qualities, prices average from £10 to £20 sterling per ton.

PALM WINE (TODDY).

The spikes of the flowers of the coconut palm produce, when subjected to fermentation, a species of spirit, or wine, known as "toddy," from which in its turn excellent sugar can be extracted.

The so-called palm wine, or toddy, is made in the following manner: The floral peduncle prior to opening of the flowers that is, from five to six months after its first appearance is bound round with twine—spirally—from base to apex, in such wise as to prevent its opening. After having been well beaten with a stick, morning and evening during three or four days, with a view to stimulating the flow of sap, a cut is made in the upper part of some 5 or 6 centimetres in length. Through said cut the "wine" begins immediately to flow.

The flow of the sap continues during some four to six weeks. One floral peduncle in good condition will yield 4 to 5 litres of "wine" daily. A good palm tree will yield from 250 to 300 litres of "wine" per annum.

Excellent vinegar can be made from the palm "wine," to obtain which it is merely necessary to expose the "wine" to the action of the sun during a period of from eighteen to twenty hours.

Toddy, when distilled, yields good alcohol, the average being 25 litres of alcohol from 100 litres of sap.

The yield of alcohol per tree per annum averages some 45 litres. As before mentioned, palm "wine" can be made to yield sugar, to obtain which it is only necessary to evaporate the "wine" slowly, taking care to add a little lime for the purpose of avoiding fermentation. As soon as the "wine" has become transformed into a syrupy paste it is spread over a surface of wood or of metal, and when the evaporation is complete there remains a sugar analogous to the raw sugar obtained from the sugar cane.

COCONUT SHELL.

The shell of the coconut has no great commercial value. It is used principally for the manufacture of buttons and of fancy articles of various kinds.

In Brazil the shells are used as fuel for the furnaces employed for drying the copra. They are very useful for such purpose, since they yield much heat with but little smoke.

TRADE IN COCONUTS.

The countries which receive most of the coconuts exported from Brazil are Argentina and Uruguay. Other important purchasers of Brazilian coconuts are Chile, the United States, the United Kingdom, France, Italy, and Portugal. The States which export the most coconuts are Pernambuco, Bahia, and Rio de Janeiro. The following statement shows the quantity and value of the export of coconuts from Brazil for the years 1908 to 1912.—

EXPORT OF COCONUTS.

Years.	Quantity.	Value.
1908	141,700	£1,235
1909	213,000	1,424
1910	136,900	912
1911	172,600	1,160
1912	236,900	1,930

VALUE OF COCONUTS.

The yield of coconuts per tree varies considerably according to the nature of the land. The average yield per tree in the various parts of Brazil varies from 100 to 150 coconuts per annum. In certain exceptional cases trees have been known to yield 200, and even 300, nuts per annum. It is calculated that one hectare of land can support some 158 coconut trees.

ENGINEERING NOTES.

Hydro-electric Power in Sweden.—The famous Elfkarleby Falls, which the *Times* describes, are situated on the Dal River, some five miles from its mouth in the Bothnian Gulf. They are divided into three branches by two islets, Laxo and Flako,

and their height at low water is about 15 metres. Higher up the river there are some other falls of varying height. A reservoir is formed by dams across these three branches above the falls proper, and from this the water is taken by a canal some 350 metres long to the power-station, which is situated on the right river bank. The dams can raise the level of the water to about 21 metres above the level of the sea. The volume of the water in the Dal River in ordinary circumstances varies from 1,300 cubic metres per second at high water, to 100 cubic metres at low water. The dams produce an increase of the water volume of 50 cubic metres per second during six or eight hours out of the twenty-four, and at the power-station a mean-water volume of 200 cubic metres per second can be reckoned upon during nine months of the year. The regulation of Lake Siljan and other lakes up the river will materially increase the amount of water available. The power-station, which is designed for 200 cubic metres of water per second, will contain five turbines, each having a nominal and maximum capacity of 11,250 h.p. and 13,000 h.p. respectively. They are of the horizontal type, with four wheels, and to their axles are directly coupled three-phase generators, each with a normal and maximum capacity of 10,000 and 12,500 k.v.a. 50 periods, and 10,000-11,000 volts. The energy is to be transmitted and distributed through 20,000, 40,000, and 70,000 volt lines. At present there is in course of construction a 70,000 volt line, 154 kilometres long, to Westeras, with a branch, 50 kilometres long, running south-east to Hallsta from Dannemora. Sub-stations will be built at Dannemora, Upsala, Enkoping, and Westeras. A 40,000 volt line, 87 kilometres long, to Hofors and Stjornsund, is under consideration. A reserve steam station will be built at Westeras. The station starts under favourable conditions, as nearly the whole of its energy has already been disposed of. The money voted for the undertaking amounts altogether to over three-quarters of a million sterling.

Hydro-electric Power Scheme in Ireland.—A more ambitious undertaking has been mooted in the *Irish Industrial Journal.* It involves the combination of two power-houses utilising the waters of the Shannon and the Erne, and capital expenditure amounting to £1½ million. The drainage area of the Shannon is 6,000 square miles, and the average discharge is given as 1,320,000 cubic ft. per minute at an available head of 40 ft., equivalent to some 60,000 h.p. all the year round. It is proposed to utilise Lakes Derg, Rea, and Allen as storage reservoirs. The catchment of the Erne is almost half of that of the Shannon, but a head of 60 ft. is said to be available. Comparatively little in the way of dams would be required, although considerable dredging would be necessary below the fall, and a conduit would be required. It is proposed to establish transmission lines to Dublin, Cork, Waterford, Kilkenny, and other centres. There appears to be some difference of opinion as to the financial prospects of the scheme in its present form.

Irrigation in India and Burma.—The total area of country under irrigation in India in 1912-13 (the latest returns) was 45,574,074 acres. This total was made up as follows:—Bengal, 2,224,125 acres; Bihar and Orissa, 4,804,770 acres; Assam, 355,918 acres; United Provinces, 9,647,374 acres; Punjab, 11,302,184 acres; North-West Frontier Province, 873,615 acres; Upper Burma, 967,770 acres; Lower Burma, 123,856 acres; Central Provinces, 905,894 acres; Madras Presidency, 9,897,750 acres; Bombay Presidency, 1,003,733 acres; Sinde, 3,274,044 acres; and miscellaneous small areas, 159,041 acres. Of the total area of 45,539,074 acres dealt with, 20,256,940 acres were irrigated by canals, 6,825,189 acres by tanks, 12,350,801 acres by wells, and 6,106,144 acres by other means. The writer of these notes has been in many provinces in India, and knows what these figures and the progress made means, especially in the Punjab. The first British work in that district, to water the Baree doab, between the Chenab and the Sutlej, was undertaken in 1850 as a relief work, following the conquest of the country. By this event the Sikh warriors—who then fought against us, and who since have become the most loyal soldiers, as is proved by the present war—were deprived of their warlike occupation, and to find them employment these subsequent great works were carried out. The area irrigated is almost entirely Crown land, which was an absolute desert previously, but is now covered with luxuriant crops. The majority of the irrigated land is held by small proprietors. Several towns, one of which has about 10,000 inhabitants, have sprung up in the district, which has a railway and a network of telegraphs, the latter being chiefly used for water regulation.

The Gas Turbine.—For large powers, the turbine possesses many advantages over the reciprocating engine, such as small floor space and even turning moment, the latter feature being essential in the driving of electrical machinery, but up to the present time turbines have always been steam-driven. It is generally recognised, however, that the internal-combustion engine is more economical in its fuel consumption than the steam engine, owing to the fact that the energy realised by combustion is directly utilised in the cylinder of the engine. A considerable amount of discussion as to the possibility of running a turbine by gas has therefore taken place from time to time. Among many considerations there has been one which appeared fatal to the idea, *i.e.*, that the temperature of the resultant gases formed by the combustion of the fuel would be destructive to the blades of the turbine. Yet we learn from the *Electrician* that the experimental gas turbine is an accomplished fact. Just before the war, a machine of

1,000 h.p. was built in Germany. It is understood, however, that some difficulty was experienced in the operation of the valves, and it was not found practicable to work the whole of the explosion chambers. The turbine is worked on the impulse principle. In the ordinary internal-combustion engine the cylinder is an explosion chamber and power cylinder combined. In the impulse gas turbine the explosion chamber is separate from the power member. There are ten pear-shaped explosion chambers grouped radially round the shaft of the turbine. In each chamber there are entry valves for air and gas. The operation is similar to the existing two-cycle gas engine, and is as follows: Air is forced into each explosion chamber in turn. The gas entry valves are then opened and gas is forced in also under pressure. When liquid fuel is employed a spraying apparatus worked by compressed air on similar lines to the Diesel engine is used. When the explosion chambers are filled with the correct proportion of gas and air, the mixture is fired by electric sparks passing between the contacts placed in several parts of the chamber. On the combustion of the charge the temperature rises, the pressure following. The outlet valve in the neck of the explosion chamber is then opened and the hot gases are forced out through a conical nozzle similar to that used in De Laval and Curtis turbines. From the nozzle the cooled and expanded gases impinge on the rotor. A fan is employed at the exhaust to assist in drawing the hot gases through the rotor. When the pressure in the explosion chamber has been spent, a blast of air is forced through to perform the office of scavenging, as in the two-cycle reciprocating engine after the completion of the power stroke. In the case of the turbine, however, the time available for scavenging is longer, and the result must be more satisfactory. A fresh supply of fuel is forced into the explosion chamber and the process continues. The exhaust gases are employed to raise steam in a small boiler, the steam being used to drive the fan, air and gas pumps, and also for the producer. It is claimed that a gas turbine would occupy only one-third of the space required for a gas engine of equal power, and would be one quarter of the weight.

The Present State of Engineering in Germany.—The Copenhagen correspondent of *Electrical Engineering* writes: "It is wrong to say that the industry in Germany is disorganised. In my opinion it has never been so organised as at present, but the whole organisation has been altered to meet the war requirements. The Government has taken over practically the whole supply of brass and copper and other metals useful for war purposes. A vast number of factories are working day and night on Government orders, and, as the German Government pays tremendous prices, the firms having this sort of work do not care for any other. However, in the electrical industry there are a large number of small firms, especially down in the Thüringen neighbourhood. Most of those firms have no Government work, but they cannot supply the usual accessories because all their stocks of metals have been taken from them. Therefore, they have now to make lamp-holders, lamp-sockets, switches, and, in fact, all accessories, of brass-covered iron. With their usual technical thoroughness and cleverness they have succeeded in producing an article of first-class quality. The finished article looks exactly like brass, can be polished like brass, and, I believe, withstands moisture and other rough treatment. For a long time the Germans have been using insulated iron wires instead of copper wires."

Electrical Enterprise in India.—In a paper on electric power in India, Mr. H. R. Speyer gives a few details of the most important power schemes in that country. The largest is that of the Tata Hydro-electric Power Supply Company, whose power-house, which has just been completed at Khopoli, Bombay Presidency, will supply 30,000 h.p., and later 60,000 h.p., to the Bombay cotton-mills. The Cauvery power scheme in Mysore has now a station capacity of 16,750 h.p., and transmits power 92 miles at 35,000 volts to the Kolar goldfields. A further 5,000 h.p. is about to be installed. The Calcutta Electric Supply undertaking has a capacity of 15,000 h.p., and the Bombay Tramways and Electric Supply Company has a station of 12,000 h.p. The largest private generating station is that of the Tata Iron and Steel Works Company at Sakchi, Bengal. There are a number of electrically worked tramways in India, but at present no railway has adopted electric traction. Several schemes are, however, being considered by the Indian state-owned railways.

NOTES ON BOOKS.

Natural History of the Adélie Penguin. By Staff-Surgeon G. Murray Levick, R.N. London: British Museum (Natural History), and Longmans, Green & Co. 5s.

No bird is more delightfully human than the penguin, and no bird is more easily studied, when once you have reached his almost inaccessible habitat; for he shows but little fear of man, and suffers him, if not gladly, at least with a tolerant indifference. Staff-Surgeon Levick, who was a member of the British Antarctic ("Terra Nova") Expedition of 1910, had unrivalled opportunities of becoming acquainted with the Adélie penguins, and in this fascinating monograph he has presented a faithful and photographic picture of them which will be a thing of joy to every lover of birds.

He begins by describing their arrival at the rookery at Cape Adare. On October 13th, 1911, a solitary bird was visible; on the 15th two were walking about on the beach; on the 16th there were about a hundred, and on the 17th, "we

could see a long line of Adélies, tailing out in snake-like fashion, as far as the horizon." The mode of progression of the travellers was laborious. "First would come a string of birds toddling along, their little legs enabling them to advance only about six inches at each step; but, going at the rate of about 130 steps per minute, they covered some two-thirds of a statute mile per hour . . . Close on their heels would come another string, tobogganing on their breasts, and using their legs as propellers, the rate of progression being exactly the same as when they walked, so that the procession kept its formation as it passed over the ice. Every now and then those that walked would flop forward on to their breasts and toboggan, and those that tobogganed would as suddenly pop up on to their legs and walk."

Anxious to study the precise manner in which the penguin sets about his courting, the author singled out one particular bachelor cock who had just arrived on the scene, and carefully followed him. "Threading his way through nearly the whole length of the rookery, he avoided the tenanted knolls where the nests where, though occasionally he seemed to glance up at them in passing. Every hundred yards or so he stopped, ruffled his feathers, closed his eyes and remained so for about half a minute, when he would rouse himself and continue on his way. Evidently he was tired after his long journey and struggling against a desire to sleep.

"Arrived at length at the southern end of the rookery, he seemed to make up his mind, and boldly ascending a knoll which was well tenanted and covered with nests, walked straight up to one of these on which a hen sat. A cock stood by her side, but the newcomer either did not see him, or refused to notice him. Sticking his beak in the ground in front of the nest, then lifting his head, he made as if to place an imaginary stone in front of the hen . a most obvious piece of dumb show.

"She took not the slightest notice of him, neither did her mate, to my surprise.

"Abandoning this quest, he went straight up to another couple who were established near by, but, seeing him coming, and evidently knowing what he was after, the cock immediately flew at him, and after a sharp fight, in which he used his flippers energetically, the interloper was driven down the side of the knoll and away from the nests, when the victor returned to his hen. With the persistence of his kind, the newcomer came straight back to the nest, but weariness seemed to overcome him, for he settled himself for a doze, in which he continued until I was too cold to await further developments."

Apart from the fighting, in which the cocks indulge very freely, the whole of the mating season is an arduous time for both parents. From the moment they arrive at the rookery until the eggs have been laid, both birds fast entirely. The reason for this is probably that while nests are being built everywhere, and the unprincipled thieves are trying to steal the stones that the more industrious birds have gathered, they dare not leave their property unprotected. Sometimes this fast is continued for as much as twenty-eight days, and yet, in spite of the fact that they have undergone a long and wearisome journey, and a long period of battle and anxiety, they seemed to be but little the worse for it.

It is pleasant to learn that, besides their hardships and anxieties, the Adélie penguins can also enjoy their sports. Bathing parties are among their favourite recreations. "To watch these parties was interesting and instructive. On leaving their nests the birds made their way down to the ice-foot on to the sea-ice. Here generally they would wait about and join up with others until enough had gathered together to make a little party, which would then gaily set off for the water. They were now in the greatest possible spirits, chattering loudly and frolicking with one another from time to time, playfully chasing each other about, or indulging in a little friendly sparring with their flippers. Arrived at length at the water's edge, the same procedure was almost always gone through.

"The object of every bird in the party seemed to be to get one of the others to enter the water first, and they would crowd up to the very edge of the ice, trying by various tricks to push each other in. As a closely packed bunch of birds stood on the brink, those behind would try to rush the front rank over, who then, barely recovering themselves, would rush round to the rear and endeavour to turn the tables on the others. Occasionally one would actually get pushed in, only, by a lightning turn under water, to bound out again on to the ice, with a movement so quick as to resemble an indiarubber ball hitting the water and bouncing out again.

"Then for some time they would chase one another about, seemingly bent on having a game, but each bird intent on avoiding being first in. Sometimes this would last a few minutes only, but often for an hour or so, until suddenly one of the number started to run at full tilt along the edge of the ice, the rest following closely on his heels, until at last he took a clean header into the water. One after another the rest of the party followed him, each taking off from the spot where he had entered, and following one another so quickly as to have the appearance of a lot of shot poured out of a bottle into the water. Then for a few seconds not a ripple would be made, and a dead silence ensue, till they would all appear some twenty or thirty yards out and start rolling about and splashing in the water, cleaning themselves and making a noise that resembled a lot of boys calling out and chaffing one another. Seemingly reluctant as they had been to enter the water, when once there they evinced every sign of enjoyment, and would stay in for hours at a time."

Another game of which the birds seemed very fond was what is called by Staff-Surgeon Levick

"excursion boats." Small ice-floes were carried by the tide past the rookery at the rate of some six knots an hour. As one of these approached it would be boarded by numbers of penguins, who sometimes crowded on to it until it could hold no more. As they sailed past close to the shore they would shout remarks to other penguins who stood on the ice-edge, and these would in turn shout back at them, so that a running fire of chaff seemed to pass between those on the bank and those on the "excursion steamer." As soon as the floe reached the lower end of the rookery, the birds would suddenly plunge into the water and swim back against the stream, only to board a fresh floe for another sail. In this way some of them would spend many hours of the day.

Another remarkable feature in the conduct of the penguins is the drill which they carry out with almost military precision, before they leave the rookery for their winter quarters. The manœuvres lasted for many hours, and seemed to be carried out on the orders of some leader.

Staff-Surgeon Levick's monograph is an extremely interesting and valuable study of these delightful penguins, who are at least as human and entertaining as the birds of Aristophanes or the inhabitants of Anatole France's Penguin Island. Its value is increased by twenty-one admirable photographs depicting the birds in various characteristic occupations and poses.

VICTORIA AND ALBERT MUSEUM. REVIEW OF THE PRINCIPAL ACQUISITIONS, 1914. Illustrated. London: H.M. Stationery Office. 1s.

In spite of the war, the year 1914 has been a fortunate period for the Victoria and Albert Museum. Of course, the finest acquisition has been M. Rodin's noble gift of his own sculpture. Next, perhaps, in importance is the Studley silver-gilt bowl, presented by Mr. Harvey Hadden, which is the earliest, and probably the most interesting, piece in the department of metalwork. In addition to this, a good many valuable pieces have been acquired. The department of textiles has been enriched by a notable Turkish carpet of the sixteenth century and a Sheldon tapestry, while Sir William Ingram has presented to the collection of illustrations a selection from 5,000 original drawings made for the principal weekly illustrated papers during the last generation.

Many of the acquisitions are illustrated in the catalogue, and very excellently are the blocks reproduced. The directorate are to be congratulated on the manner in which the book is presented: it not only serves to inform the public as to the acquisitions to the museum for the period under review, but is a record of permanent interest to the connoisseur.

CHATS ON JAPANESE PRINTS. By Arthur Davison Ficke. London: T. Fisher Unwin. 5s. net.

The history of the Japanese colour print is among the romances of art. The artists belonged, as a rule, to the Popular School of Japanese Painters, and were socially of the rank of artisans. They received little or no recognition from the aristocratic school of painters or their patrons. "Even as artisans," says Mr. Edward F. Strange, "they were graded below the swordsmiths, metal-workers, and makers of lacquer. Many of them lived in extreme poverty, and occasionally they were driven to the practice of various other humble callings in order to get a living. Thus, Hokusai had at one time to take to selling calendars and red pepper in the streets; Hokkei was a fish-hawker; Kunisada kept a ferry." They looked for patronage to the lower classes, and catered for the theatres, the tea-houses, and the *Yoshiwara;* and consequently their prints were sold for a few pence in the streets.

Up to fifty years ago these works were practically unknown in Europe. Among the first European collectors were Whistler and Rossetti, who found examples in Paris about the year 1859. In 1862 much interest was aroused in Sir Rutherford Alcock's collection, which was shown at the International Exhibition of that year, and since that time the cult of the Japanese print has rapidly extended.

Mr. Ficke, who has devoted much time and study to the subject, writes an interesting history of the art, dividing it into five periods: the Primitives, the early Polychrome masters, Kiyonaga and his followers, the Decadence, and the Downfall. From considerations of convenience, all the examples with which the book is lavishly illustrated have been taken from American collections; but this restriction matters the less, as many very fine specimens have found their way to the United States.

Not the least useful chapter of the book is the last, in which Mr. Ficke writes of the collector. He gives some sound advice to the buyer of Japanese prints, suggesting the general lines that should guide him in making his selection, and adding some valuable hints about prices. The reader who has assimilated the knowledge here contained will be able to face the dealer with little fear of suffering for his temerity.

GENERAL NOTES.

TECHNICAL RECRUITS FOR THE ROYAL ENGINEERS.—A number of young men between the ages of 17½ and 19 are required to join the Royal Engineers for the purpose of training as telegraph and wireless operators. The men required are those who have attended polytechnics or technical schools throughout the country. Those joining will be required to enlist in the Royal Engineers at the usual rates of pay. They will then be sent to the General Post Office, or one of its branches, for the course of training, after which they will be attached,

according to the exigencies of the service, to the Royal Engineers or to the Royal Aircraft Corps. As the session in many of the institutions has closed, it is difficult to acquaint those who may desire to avail themselves of this opportunity. Mr. Robert Mitchell, director of education at the Polytechnic, Regent Street, W., will therefore be glad to forward full particulars to any young man wishing to join this special branch of the Army.

CUBAN SUGAR OUTPUT.—A recent issue of the *Cuba Review* gives the following figures, showing the output, in bags of 325 lb. net, of the active sugar plantations of Cuba during 1914, and the estimates for 1915, by provinces:—

Provinces.	1914.	1915.
	Bags.	Bags.
Habana	2,117,026	2,077,000
Pinar del Rio. . .	352,002	317,000
Matanzas	3,634,294	3,853,000
Santa Clara . . .	5,175,559	5,360,000
Camaguey . . .	2,062,998	1,995,000
Oriente	4,515,939	4,414,000
Total . .	17,857,818	18,016,000

GREEK MERCANTILE MARINE.—One of the most remarkable phases in the development of Greece, according to His Majesty's Consul at the Piraeus, has been the steady expansion of the Greek mercantile marine within recent years. At the end of 1903 the number of vessels comprising the merchant fleet of Greece was 210 steamers, with a combined tonnage of 202,140 tons; at the end of 1914 it was 440 steamers, with a tonnage of approximately 900,000 tons. The increase in shipping rates since the South African War has contributed largely to this expansion, and certainly has had an extraordinary influence on the economic situation of the country. According to statistics published by a local journal, 85 steamers of 219,450 gross tons were added to the Greek flag between July, 1913, and the end of December, 1914. The value of these steamers, reckoned at an average of £8 per ton gross, amounts to £1,755,600, and the total value of the Greek mercantile marine amounts to about £6,800,000. It is estimated that the savings which the Greek mercantile marine will realise in 1915, as a result of the war, will exceed £3,000,000.

INDIAN INDIGO.—At the Indigo Conference held in Delhi in February last the possibility of assisting the industry was considered from three points of view: agricultural, research, and commercial. It was generally agreed that on the agricultural side everything possible was being done by the Government, and that the outlook was distinctly promising. Valuable discoveries have been made by Mr. and Mrs. Howard, and if their recommendations be followed and an adequate supply of good seed could be secured, the plant would be less liable to wilt and the outturn would be increased. In regard to the difficult question of research, the conference considered that if indigo was to be placed on the market in excess of the present demand for cake, a chemist should be appointed who would work on the standardisation and purification of natural indigo, and on its preparation in the form most suitable to consumers. This recommendation is now being considered by the Government of India. The most important commercial question discussed was the preferential treatment of natural indigo, and the preferential treatment which might be given to synthetic indigo manufactured in England. The proposal is now under consideration. In this connection it is announced for general information that in view of the shortage of indigo, and in order to prevent the speculative withholding of stocks, His Majesty's Government have purchased supplies of natural indigo through the ordinary trade channels and in the open market.

COAL IN THE UNITED KINGDOM IN 1914.—The General Report on Mines and Quarries for 1914 shows that the output of coal from mines under the Coal Mines Act, which was 287,411,869 tons in 1913, fell to 265,643,030 tons in 1914, a decrease of 21,768,839 tons. For the period January to July the number of persons ordinarily employed at these mines was 1,133,746, an increase of 5,856 on the figures for the whole of 1913; but, owing to the heavy depletion of labour due to recruiting in the last five months of the year, the number of persons employed fell to 981,264.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 28...Geographical Society, Burlington-gardens, W., 8.30 p.m. Mr A. R. Hinks, "The Map of Europe and the Near East, compiled by the Society for the General Staff."

TUESDAY, JUNE 29...Asiatic Society, 22, Albemarle-street, W., 4 p.m. Professor P. Van Den Ven, "Byzance et les Perses à l'Époque de Justinien."

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, W., 4 p.m. Viscount Bryce, "The Influence of Religion in the Rise and Continuance of the Roman Empire."

East India Association, Westminster Palace Hotel, S.W., 4.15 p.m. Dr. J. Pollen, "Russia and India."

WEDNESDAY, JUNE 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Annual General Meeting.

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Professor G. Baldwin Brown, "Was the Anglo-Saxon an Artist?"

FRIDAY, JULY 2...Royal Historical Society, 22, Russell-square, W.C., 8.30 p.m. Professor C. H. Firth, "Military Ballads."

Journal of the Royal Society of Arts.

No. 3,267. VOL. LXIII.

FRIDAY, JULY 2, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

SPECIAL WAR LECTURES.

The Council have arranged with Professor Vivian B. Lewes to give a short course of special lectures during the recess on "Modern Munitions of War." Three lectures will be given at 4.30 p.m. on Wednesday afternoons, July 7th, 14th, and 21st.

The first lecture will deal with "Guns and Propellants," the second with "Mines, Shells, and High Explosives," and the third with "Poison Gases and Incendiary Bombs." The course will be given under the Fothergill Trust.

The lectures will be open to all Fellows of the Society, who can admit their friends personally, or by the usual tickets. Any Fellows requiring further tickets can apply to the Secretary, who will furnish them with any number they may desire for distribution. Tickets will also be issued gratuitously to any persons interested in the subject who may apply to the Secretary.

EXAMINATIONS.

The results of the Advanced Examination (Stage III.), held from May 10th–19th, were sent to the centres on June 29th. It is hoped to issue the Intermediate (Stage II.) results about the middle of this month, and the Elementary (Stage I.) early in August.

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The one-hundred-and-sixty-first Annual General Meeting for receiving the Report of the Council, and the Treasurers' Statement of Receipts and Payments during the past year, and also for the Election of Officers and New Fellows, was held in accordance with the By-laws on Wednesday last, June 30th, at 4 p.m., COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Chairman of the Council, in the chair.

THE SECRETARY read the notice convening the meeting, and the Minutes of the last Annual Meeting.

The following candidates were proposed, balloted for, and duly elected Fellows of the Society:—

Amenomori, Kikutaro, Nakanocho, Higashi-Sambongi, Kyoto, Japan.

Armstrong, Sir Charles H., care of The Chartered Bank of India, Australia and China, 38, Bishopsgate, E.C.

Armstrong, Sir Walter, Hon. R.H.A., 63, Carlisle Mansions, Victoria-street, S.W.

Bashiram, Sabgal, M.A., Assistant Engineer, P.W.D., Amritsar, India.

Blackmore, Henry Spencer, P.O. Box 145, Mount Vernon, New York, U.S.A.

Chandavarkar, Sir Narayan Ganesh, B.A., LL.B., Pedder-road, Bombay, India.

Chetty, T. N. Nacheapa, Ramachandrapuram, Pudukkottai State, S. India.

Davies, Rev. A. W., St. John's College, Agra, India.

Dawson, James Alfred, 18, Princess-street, Quittah, Gold Coast Colony, British West Africa.

Denning, John Renton, Punjab Chamber of Commerce, Delhi, India.

Devlin, Thomas, Lehigh-avenue, American and Third Streets, Philadelphia, Pa., U.S.A.

Dutt, Upendra Nath, 2, Puttuldanga-street, Calcutta, India.

Fox, Thomas, *Times of Malaya* Office, Ipoh, Federated Malay States.

Fujioka, Ichisuke, 21, Higashimachi, Azabu, Tokyo, Japan.

Gibb, Andrew, Messrs. Bathgate & Co., 19, Old Court House-street, Calcutta, India.

Grant, Alfred Charles, Montego Bay, Jamaica, British West Indies.

Gray, Joseph Milton, J.P., Georgetown, St. Vincent, British West Indies.

Gurney, Sir Eustace, Sprowston Hall, Norwich.

Horn, David Wilbur, A.M., Ph.D., Bryn Mawr, Pennsylvania, U.S.A.

Khan, Haziq-ul-Mulk Hakim Mahomed Ajmal, K.I.H., President, Anjuman-i-Tibbia, Delhi, India.

Leslie, Lieut.-Colonel F. M., Volunteer Headquarters, Strand-road, Calcutta, India.

Mishra, Pandita Damodardas, Hardwar, United Provinces, India.

Nakamatsu, Morio, Araijuku, Triarai Mura, near Tokyo, Japan.

Palanpur, His Highness Nawabzadah Taleymohommed Khan Saheb of, The Palace, Palanpur, North Gujarat, Bombay, India.

Porter, Thomas, Lilsdaal, Greenwood Park, Natal, South Africa.

Pybus, Ernest H., Liapari, Villa Lavella, British Solomon Islands.

Pyne, Charles A. Beynham, Grosvenor House, Calcutta, India.

Rau, J. Krishna, B.A., Napier-park, Madras, India.

Seshadri, Principal P., M.A., The Salem College, Salem, India.

Singh, Raja Durga Prosad, Lajbari, Jharia, Behar and Orissa, India.

Spackman, Mrs. Samuel, The Goring, Grosvenor-gardens, S.W.; and Philadelphia, U.S.A.

Starkey, Harold Augustus, A.M.I.E.E., care of Messrs. W. T. Henley's Telegraph Works Company, Ltd., 7, Hummum-street, Bombay, India.

Stone, Henry, British Consular Agent, Cerro de Pasco, Peru, South America.

Stringfellow, Charles Albert, British Consular Agent, Talca, Chile, South America.

Sutton, E. Stanley, care of Manáos Harbour, Ltd., 11, Adelphi-terrace, Strand, W.C.

Thornton, Thomas, Department of Agriculture, Ilorin, N. Province, Nigeria, British West Africa.

Wadleigh, Francis R., 426, Real Estate Trust Building, Philadelphia, Pennsylvania, U.S.A

Williams, David D., 17, Montpelier, Edinburgh.

The Chairman appointed Mr. Harold Oakley and Mr. H. B. Wheatley, D.C.L., F.S.A., scrutineers, and declared the ballot open.

The Secretary then read the following—

REPORT OF COUNCIL.

Before the commencement of the present session a notice was issued to all the Fellows indicating the line of action which it appeared to the Council the Society should pursue under the changed conditions in which the session opened. The notice pointed out that, as far as the Society itself was concerned, a condition of warfare was in its early years no novelty. Though the Society was started in a brief interval of peace, the first half century of its work was an almost uninterrupted period of war, and although not many references to war are to be found in the earlier volumes of the *Transactions*, the series of which commenced in 1783, yet in the very earliest records of the Society there are numerous indications of the effect of war upon the industries of the country. After Waterloo we had in Europe a century of peace, broken only by the short interval of the Crimean War; and now we are approaching the end of the first year of a conflict such as our country has never before known.

When this notice was issued at the beginning of last November, it was anticipated that the Society would suffer very heavy losses of numbers and consequently of revenue, and that there would be great difficulties in the way of carrying out its usual programme. As regards the business of the Society, it may be said that these anticipations have been in no way realised. The ordinary work has been carried through in the ordinary way, and, so far as regards the papers read and the attendance at the meetings, the present session compares quite favourably with any of recent years. As regards personal and pecuniary losses, the anticipations have not been realised to the extent which was expected. There has naturally been a heavy falling off in the number of new Fellows, only 148 having been elected in comparison with 227 last year. But the number of resignations caused by the war, though considerable, has not been as heavy as was feared. The total number of deaths and resignations for this session amounts to 287 as compared with 241 last year. The actual result is that there is a falling off in numbers of 139, and financially a reduction as compared with last year of £460 in annual contributions, besides £86 in Life Subscriptions.

As the Fellows are aware, the Society's revenues have fallen away during the past few years, and the additional losses caused by the war have brought the balance between expenditure and receipts to the wrong side. It was evident, therefore, that the Society had to fall back upon the accumulations of past years, which during the period from 1880 to 1905 reached the sum of over £20,000. Rather fortunately it happened that one of the Society's investments—£1,400 of Queensland

4 per Cent. Bonds—was paid off at the beginning of June, and the Council were thereby saved from the disagreeable necessity of realising any of their investments by a forced sale on a low and falling market. The transfer of the amount realised from capital to revenue has placed the Society in a satisfactory financial position for the time being. But the Fellows must understand that, unless further public support by the addition of new Fellows can be obtained, the Society cannot be continued on its present footing for any great number of years. That the Society has not suffered more than it has during a year of war is a matter for legitimate congratulation; but after the war is over, and normal conditions are again attained, the Society will have a certain amount of leeway to recover, and unless its Fellows make up their minds to support it, it may have to face a period of insufficient revenue, inadequate resources and impaired efficiency.

I. Ordinary Meetings.

The programme for the Society's evening meetings was, like everything else, gravely affected by the war. Several papers, already promised, had to be abandoned in consequence of their authors having joined the Army, or being occupied in national service at home. Eventually it seemed best to devote a certain number of evenings to subjects more or less connected with the war, and at the same time to continue the usual practice of providing a selection of papers of the ordinary character. In the outcome, a large proportion of the papers —nearly half, in fact—dealt with matters connected with industrial and economic questions arising out of the war, while the remainder were devoted to the usual topics with which the Society is concerned.

The opening Address of the Chairman, Sir Thomas Holdich, after dealing at some length with the Society's Examinations, turned to the discussion of a topic on which Sir Thomas is admittedly one of the best living authorities, that of surveying and map-making, and gave some interesting information about the newest details of that science.

The first two papers after the opening Address dealt with that question of industrial supplies to which attention was first devoted after the breaking out of the war, namely, the supply of chemicals. It has been for long a matter of common knowledge that almost the whole of the chemical reagents employed in industries in this country came from Germany. This is especially the case as regards drugs and the "fine chemicals" used for photographic and other similar purposes. Like conditions prevail in the case of industrial products produced by chemical methods. A typical instance of this last case is the supply of dye materials. The story has been told over and over again how the infant industry of the development of coal-tar colours originated in England, and, after being carried on to a considerable point of success, was transplanted to Germany, and there, by a combination of skilfully applied capital and wisely directed chemical research, developed into by far the greatest scientific industry which the world has ever known. The natural result was that the manufacture of coal-tar dyes, with all the innumerable products associated with their manufacture, came to an absolute cessation in England, which has been allowed to rely wholly upon Germany for all the chemical products required. The whole subject was very ably dealt with in the two papers above mentioned, one by Sir William Tilden, when Sir William Ramsay presided, and the other by Dr. W. R. Ormandy, when Lord Moulton was in the chair.

Of the similar papers which have been read since Christmas, there is nothing invidious in saying that by far the best was the admirable paper by Professor W. J. Ashley on "The Economic Position of Germany," which was read at the end of February. It was a masterly exposition by one of the most competent authorities in the country of the actual economic state of Germany, so far as it was known or could be known at the time. It received well-merited commendation from the press, both metropolitan and provincial, and performed a most useful service in providing the public with such information as was available about the present condition and future prospects of the enemy country.

Another extremely useful paper was the one read by Mr. J. A. Hunter on "The Textile Industries of Germany and Great Britain." Mr. Hunter pointed out very clearly what were the respective classes of goods which were mainly produced in the two countries, and showed what the goods were which we could produce in the most economical manner, and what others there were the manufacture of which we could perhaps take up in view of the probable altered conditions at the end of the war. On the whole, Mr. Hunter argued that we might look rather for a change than for the

extinction of trade, and he thought as British industry was financially better able to carry the burdens of war than German industry was, it was more likely to attract to itself trade hitherto German than is German industry to carry away business hitherto British.

A little later in the year Mr. Octavius Beale dealt generally with the expansion of British industry after the war, and suggested means by which a regular system of manufacture could be developed in the Dominions and Colonies. Another general paper was that by Mr. J. W. Gordon, who laid stress on certain points in the existing Patent Law which in his opinion hindered the transfer and development of hostile industries. A third was by Mr. Moreton Frewen, who suggested that the development of certain colonial fisheries might provide useful employment, not only for the surplus of our own fishermen, but for a considerable number of discharged soldiers after the war was over.

Lady Lugard's paper on "The Work of the War Refugees' Committee" should be mentioned in this category, as an interesting record of the vigorous and successful attempt which was made to grapple with the sudden emergency caused by the influx of Belgian refugees into this country.

The remaining papers read this year were of the ordinary general character, and it is satisfactory to be able to report that in value and interest they were quite on a level with those of recent sessions. It cannot, therefore, be said that in this respect the Society has suffered from the war. At the second meeting in December, Mr. W. A. Young, who was largely instrumental in the organisation of the attractive collection of British metalwork in the Victoria and Albert Museum, read a very interesting paper on "The Domestic Metal Work of the Eighteenth Century," the time when probably the greatest development took place in the manufacture of household wares, including stoves, kitchen utensils, and all the various wares of brass, tin, and pewter, which about this time, to a large extent, took the place of the utensils made of wood for poor folk, and of silver for rich ones.

At the last meeting before Christmas Sir William Abney gave the results of a long-continued series of experimental observations begun many years ago in order to test pigments for permanence of colour. His paper, which did not profess to contain much new information, was valuable as affirming or correcting various ideas as to the permanence or instability of certain colours. It is obvious that tests of this sort must extend over a long period of time, as it was not safe to assume before the fact had been verified that the effect of strong light for a short period on the fading of a tint is identical with the results produced by long exposure to a fainter light.

The Hon. John Collier's paper on Portrait Painting gave a clear and most interesting exposition of the technique of certain selected Great Masters, and showed how the principles founded on a study of that technique had influenced modern painters.

Mr. Vincent Brooks, than whom no one has a longer experience of the subject, gave an account of British Lithography in 1915, which may be looked upon as an interesting supplement to the valuable course of Cantor Lectures given last session by Mr. Joseph Pennell.

In his paper on "The Decorative Textile Industries and the Designer's Relation thereto," Mr. Arthur Wilcock seemed inclined to take a somewhat gloomy view of the designer's position. The most that the designer should expect was that he should be recognised by his fellow designers and a few experts in the trade. He need not look for general recognition, and his artistic aspirations must always be strictly subordinate to the dictates of fashion and commercialism. Mr. Wilcock also discussed the question of the education of the designer, and deprecated the present tendency of the Art Schools of the country, which, he urged, gave too little specialised training, and made no effort to connect the work of the students with trade conditions, the result being that large numbers of so-called designers were turned out every year who had no practical knowledge of the industries for which they proposed to design.

Mr. William Poel's paper on Shakespeare's Profession had the special interest of dealing with an art which has received but scant attention from the Society—a disregard which may be excused from the fact that the art of the actor is hardly capable of being associated with industrial applications. Having regard to the general condition of things in the country, the author showed a certain boldness in comparing, rather to our enemy's advantage, the management of German theatres as regards the production of masterpieces with those of this country. But Mr. Poel's views as to the importance of the actor's share as compared with the extraordinary development of scenic

appliances were thoroughly appreciated by the audience.

In his paper on "The Industrial Uses of Coal Gas," Mr. H. M. Thornton gave an exhaustive account of the numerous applications of gas to purely manufacturing purposes. It must have been more or less a revelation to all who are not specially cognisant of the developments of gas manufacture to know in how very many cases gas has taken the place of solid fuel for industrial purposes. This application of gas is of comparatively recent introduction, and the Chairman of the meeting mentioned the fact that when Sir Corbet Woodall took the chair at a meeting of the Society thirty-five years ago, he stated that at that time not more than 5 per cent. of the gas used was employed for purposes other than lighting. At present about 40 per cent. is so used, and yet it was the opinion of those best qualified to speak on the matter that this only marked the beginning of the era of the industrial application of gas.

It must be admitted that in his paper on "The Industrial Uses of Radium" Mr. Thorne Baker rather dealt with the future than with actual achieved results. He, however, gave a very interesting account of the experiments which had been made to test the effects of applying solutions of radium salts to aid vegetable growth, and held out considerable prospect that these experiments justified the expectation of valuable results in the immediate future.

Mr. A. S. E. Ackermann's paper on "The Utilisation of Solar Energy" was a very complete account of the various experiments made with a view of employing the direct heat of the sun for the production of power, and showed very clearly how far these results had been satisfactory. There seems every reason to hope that before long we may get in tropical countries engines driven either by steam generated directly by the sun's heat, or by some more direct application of solar energy.

Dr. Augustus Vernon Harcourt's contribution was mainly intended to describe a simple instrument he had constructed for the measurement of radiant heat from domestic fires, and a grate he had himself devised for the economical combustion of coal. It, however, contained also a good deal of information on the subject generally. An interesting side issue was his demonstration of the futility of expecting to increase the amount of heat generated from coal by the use of any nostrums applied to the fuel during combustion.

Mr. Charles Darling, in his paper on "Recent Progress in Pyrometry," may be said to have completed the information provided in his Cantor Lectures of 1911, by bringing the matter down to date; and he certainly showed that there had been very considerable progress made in Pyrometry since the admirable course of lectures referred to.

II. Indian Section.

Although the session was a difficult one in some respects, no falling off occurred either in the number or merit of the papers. The discussions also were for the most part quite up to the average, while the audiences throughout were as large as, and in some instances larger than, in normal times. With only one exception, the subjects selected for treatment related directly or indirectly to the war.

It was felt that the programme would be incomplete unless it provided an opportunity for the consideration of the effect of the widespread disturbance of peace on the external trade of India. That trade, so far as exports are concerned, was, until August last, largely carried on with the continent of Europe, Germany being, next to the United Kingdom, India's best customer. Mr. M. M. S. Gubbay, I.C.S., then in England on special duty connected with the war, agreed to read a paper on the subject, but was unexpectedly recalled to India to superintend the purchase and export of the surplus wheat supplies of that country. Fortunately the Society found an eminently qualified substitute in Sir Charles H. Armstrong, recently Chairman of the Bombay Chamber of Commerce, and a former member of the Bombay and Viceregal Legislative Councils. Having only lately arrived from India, Sir Charles Armstrong was in a position to give the Society first-hand information regarding the dislocation of trade brought about by the outbreak of hostilities, and to describe the measures taken to deal with the situation. "Looking back a few months, it is," he said, "wonderful how the Indian trade in merchandise has revived, and how rapidly India has adjusted itself to new conditions, and, in many cases, to much higher prices." There is, he was able to say, no reason at the present time to take a pessimistic view of the future. With respect to the not inconsiderable market in India for many kinds of goods previously obtained from Germany and Austria, he spoke hopefully of the efforts which are being made to capture that trade for English manufacturers.

Incidentally, he asked that the question of appointing a commercial man of fresh Indian experience to a seat in the Secretary of State's Council, a reform much desired by the mercantile community of India, might be favourably considered. The Marquess of Crewe presided, and his presence in the chair was noteworthy not only on account of the importance of the speech he delivered, but because it was almost his last public act as Secretary of State for India. In thanking his lordship for attending at a juncture when the call on his time was so great, the Chairman of the Section mentioned that for twenty years or more it had been the practice of Secretaries of State to show their interest in the work of the Society's Indian Section by on occasions taking the chair at its meetings; and Lord Crewe, in reply, said it was a distinct pleasure to him, as well as his duty, to follow the example referred to.

For some time past a once flourishing Indian industry, the cultivation of indigo, has been tottering to its fall. Formerly the value of the annual production amounted to between three and four millions sterling, and employment was afforded for many hundreds of young educated Englishmen; in 1914 the value of the out-turn was less than £70,000. Synthetic indigo, the successful rival of the natural product, having disappeared from the English market owing to the war, Indian indigo is for the moment at a premium, and this fact has strengthened the hopes, always entertained by at least a minority of their number, that prosperity may yet return to the Bengal planters. The question was fully discussed at one of the earlier meetings of the session, when an excellent paper, dealing with the position of the industry as a whole, was read by Dr. F. Mollwo Perkin. While advising the Indian growers to make the most of their present opportunity by increasing the area of cultivation and improving their methods, he expressed himself cautiously with reference to the prospects, say, three years hence. "If after a few years' trial it is found that the indigo planter is unable to meet the demand, and if it can be proved that better results can be obtained with synthetic indigo, then the natural indigo industry – like the natural alizarin obtained from the madder plant—must cease to exist." Nevertheless, he himself considers natural indigo best for many classes of material, and agrees that its use should be enforced in all contracts executed for State departments. The general tone of the discussion was not altogether optimistic; but one of the Mincing Lane experts who spoke thought that the Indian grower could compete with any synthetic indigo that it may be found possible to make in this country. This opinion is based on the assumption that English synthetic indigo cannot be sold at less than 1*s.* per lb., double the price of the Badische article.

Mr. Perceval Landon's brilliant and picturesque paper on "Basra and the Shatt-ul-Arab," which happened to coincide with important war despatches from the Persian Gulf, aroused much interest. After dealing with the history, geography, and political status of the "solar plexus of the old world," as he described Basra, and of the Shatt-ul-Arab, one of the outer gates of India, he indicated some of the problems that will have to be considered after the war in settling what is to be the future of Southern Mesopotamia. The most important of these problems is our responsibility for the development and good government of these vast alluvial flats. He submitted (1) that we have no right to abandon the regions without seeing that some form of what the Viceroy of India, Lord Hardinge, has called "benign administration" is secured; (2) that we cannot allow the country to return to the administration of Constantinople or Konia; and (3) that we have to protect much more than our own material interests. Earl Curzon of Kedleston, to whom, as Mr. Landon said, is due in a large measure the monopoly we have continued to maintain upon the waters of the Persian Gulf in spite of German intrigue, presided, and in the course of a powerful speech urged that it should be the immediate object of our diplomacy to detach the Arabs from the Turks, and to resume with the former those pleasant relations which have characterised our policy during the last fifty years. With regard to the intrigues referred to, he declared that there must be an end once for all to German influence in Lower Mesopotamia. Sir Hugh Barnes also contributed to a singularly instructive discussion, and brought forward facts, hitherto not made public, to show that until quite recently German gold was still being used to seduce the Arabs from our side to that of the Turkish interlopers.

At a meeting presided over by Viscount Bryce, an interesting paper on "The Indian Army" was read by Lieut.-Colonel Arthur C. Yate, formerly Commandant of the 129th (Duke of Connaught's Own) Baluchis. In setting forth

his "idea of the mould in which the Indian Army has been so shaped that it has become to-day a world power," he surveyed the successive great changes in the composition and organisation of that Army from the time when the nondescript forces of the old East India Company largely consisted, according to contemporary historians, of the "sweepings of the English ports," down to the present day, when their successors are constantly proving their value as fighters on battlefields in three continents. The historical section of the paper included vivid descriptions of famous Indian wars and of the deeds of some almost forgotten military heroes. Lord Bryce paid a fine tribute to the Indian forces at the front. They had, he said, shown themselves worthy compeers of our own troops and the troops of our Allies, not only in courage, but in endurance of hardships and unfailing loyalty. It was, he added, one of the redeeming incidents of a time so full of sorrow for all, that such a spirit of attachment should have been shown by the people and princes and troops of India to the British Empire.

The paper by Mr. H. J. Elwes, F.R.S., giving an account of the visit recently paid by him and Mr. Aubyn Trevor-Battye to Nepal, the home of the gallant Gurkhas, afforded the Society an opportunity such as only now and then occurs of hearing about a country which, though very friendly to the British ráj, is still quite inaccessible to Englishmen, whether travellers, sportsmen or Government servants, unless invited by the *durbar*. Mr. Trevor-Battye supplemented Mr. Elwes's entertaining narrative by supplying some admirable notes on the much-admired architecture and wood-carving of Nepal, specimens of which, as photographed by him, were shown on the screen. So far as circumstances permitted him to judge, the system of government prevailing in this secluded Himalayan State—paternal despotism—appeared to Mr. Elwes to be suited to the people, but, as an arboriculturist, he noticed with regret that the Maharaja's forests are not managed in a way that would enable them to supply the growing deficiency of timber in Bengal and the United Provinces, and thus become a valuable asset.

The remaining paper was read by Sir George Duff Sutherland Dunbar, and gave a very valuable description, based on personal inquiry, of the manners, customs and religious beliefs of the primitive Abor and Galong tribes living in the Brahmaputra Valley. Sir George Dunbar's evidently laborious investigations were chiefly made in the course of adventurous explorations undertaken by him while serving as an officer in the Assam Military Police. So replete was the paper with matter of ethnological and general interest that Sir Thomas Holdich and others acquainted with the North-Eastern border expressed the hope that in the near future Sir George Dunbar would expand it into a book.

III.—Colonial Section.

As usual four papers were read, the programme covering a very wide field, and dealing with many subjects of great interest.

One of the most pressing of the numerous and momentous economic problems that faced our rulers in August last was the threatened serious shortage of sugar, and the rise in the cost of that commodity to double the ordinary amount. The bold and effective measures taken by His Majesty's Government to reduce prices to something like the customary level, to keep the market well supplied, and to prevent a "corner" being created at the expense of the consumer, formed one of the many points discussed by Mr. Edward R. Davson in his able paper on "Sugar and the War." The main purpose of the paper was to direct attention to the danger of again relying upon foreign sources for so large a portion of our supplies—previous to the war 60 per cent. came from Germany and Austria—and to propose certain remedies. Speaking with intimate knowledge of the trade, Mr. Davson maintains that of the two million tons of sugar annually consumed in these isles, the major part ought to be, and in certain conditions can easily be, obtained within the confines of our own Empire. Those conditions briefly expressed are State encouragement of beet-growing in the United Kingdom, and the temporary repeal of the duty on Colonial imports. With regard to beet cultivation, he urges the Government to grant or guarantee the amount required, probably £250,000, to establish a factory on a sufficiently large scale to give the experiment a good chance of success. Finally, he asks that the question may be treated "not so much in accordance with the rules of text-books and traditions and creeds as in accordance with the needs of this country which emergency calls forth." In the speeches that followed Mr. Davson's views were generally supported.

In his admirable paper on the economic development of British East Africa and Uganda,

in which for some years past he has taken an active part, Major E. H. M. Leggett showed how the two great "Imperial estates" are complementary one to the other, each supplying something that the other lacks, so that the course of their expansion, in part due to organised effort and in part almost automatic, tends more to dependence upon a centralised programme. Lastly, he indicated something of what he believes to be the inevitable influence of these fertile territories as governing the economic future of about a third of tropical Africa, this power following from the fact that the port of Mombasa is the gateway of the shortest route to the great inland waterways—Lake Victoria, Lake Chioga, Lake Albert, and the head-waters of the Nile.

One attractive feature was the paper on "The Northern Territory of Australia," read by Mr. David Lindsay, well known for his explorations in that neglected but not unpromising region. Four and a half times the size of the Mother Country, endowed with magnificent harbours and rivers, possessing millions of acres of rich agricultural land, abounding in minerals, and with a climate, especially in the hinterland, not unsuited to white men, the total population of this great lone land is scarcely more than 3,500, and of these a thousand appear to be aboriginals and five hundred Chinese, the latter being employed in the mining industry. A little more than four years ago the Northern Territory was transferred from South Australia to the Commonwealth, and since then something has been done towards providing the indispensable railways; but otherwise, according to Mr. Lindsay, the results of the new *régime* so far are rather disappointing. That greater progress has not been made is, he suggests, due to the fact that the Commonwealth officials have not availed themselves of the knowledge and experience gained by South Australia during the forty-five years she had control of the Province. Until the railways recommended by the Royal Commission, of which he was a member, and estimated to cost between seven and eight millions sterling, are constructed, the Northern Territory, he says, will have no chance of being settled and developed. The High Commissioner (Sir George H. Reid), who presided, took a sanguine view of the prospects of the Territory, which he predicts will in time become "one of the most important parts of Australia."

Ten years ago a valuable paper on "The Use of Wood Pulp for Paper Making" was read at an Ordinary Meeting of the Society by Mr. S. Charles Phillips. At the closing meeting of the Colonial Section, on May 4th, the same gentleman read an equally valuable paper on "The Empire's Resources in Paper-making Materials." The advance made by the lucrative wood-pulp industry of Canada in the past decade was referred to, and much useful information given respecting the potentialities, particularly in suitable fibres, of other parts of the Empire. Our dependence on the Scandinavian countries for chemical and mechanical pulp, he pointed out, has not been without a certain amount of risk recently. With a ready market at its own doors and with contracts to fulfil, Canada could scarcely be expected to meet anything like the requirements of this country. Hence the greater need for exploiting and developing all our resources. Sir Daniel Morris, who took part in the discussion, spoke very highly of the possibilities of Newfoundland, whose proximity to these shores, illimitable supply of raw material, and cheap labour, appear to give the oldest of our colonies a "great advantage over any other portion of the Empire in the production of wood pulp and paper."

IV.—Cantor Lectures.

The first of the courses of Cantor Lectures for the past year was on "The History and Practice of the Art of Printing," by Mr. R. A. Peddie, whose interesting paper on the history of Colour Printing read in the previous year will be in the memory of those who are familiar with the subject. To condense into four lectures a history which extends over nearly five centuries was a task of no small difficulty; but by severe compression and careful selection Mr. Peddie accomplished his task satisfactorily. Of necessity, he dealt with the subject chronologically, devoting one lecture to the earlier history down to the end of the eighteenth century, while the second lecture dealt mainly with machinery and typography, the third to a large extent with black-and-white illustration, and the fourth with the later history of colour printing.

Of the three lectures which composed Dr. Mollwo Perkin's course upon "Oils, their Production and Manufacture," the first two were devoted to mineral oils, and the third to vegetable oils. In both cases the lecturer dealt with the sources of production and the treatment of the finished product. The

question of the uses of mineral oils, and of the various products derived from them, has been so fully treated before the Society in various lectures and papers, especially in the recent course of Fothergill Lectures on "Motor Fuel" by Professor Vivian Lewes, that Dr. Perkin was able to condense his remarks in this portion of the subject, and therefore to spare a whole lecture for the important subject of oils derived from vegetable sources.

Mr. M. H. Baillie Scott, in his course of lectures on House Building, dealt mainly with the artistic side of the question, and treated his subject partly historically and partly when he came to deal with houses of the present time—practically. The whole course was very fully illustrated with a number of interesting photographs of existing houses, old and new, many of the latter being of the lecturer's design.

The last course was by Dr. David Somerville on Foodstuffs. It dealt entirely with the biological, physical, and chemical side of the question. Dr. Somerville showed the nature of foodstuffs, and their action upon the human body.

V. FOTHERGILL LECTURES.

A course of three lectures was given last session under this Trust by Professor Vivian B. Lewes, who dealt with the subject of Motor Fuel. His first lecture dealt with the production and character of Petrol, his second with Petrol Substitutes, and his third with "Cracked" Spirits. The whole course was very appropriate to the present time, when the use of petrol as a fuel on land, on the water, and in the air has become so important for warlike purposes.

VI.—ALDRED LECTURE.

The fact of M. Paul Lambotte, Director of Fine Arts under the Belgian Ministry of Science and Arts, being now resident in this country—he, like so many of his compatriots, having been driven out of his own country by the war—led to his being invited to deliver a lecture under the Aldred Trust on Belgian Art. The precise subject selected by M. Lambotte was "L'Evolution de l'École Belge de Peinture (1830–1900)," and the result was a brilliant historical essay on recent masters of Belgian painting, delivered in his own language by the most competent authority on the subject.

The success of this lecture led M. Lambotte to offer to complete the treatment of the subject of Belgian Art by delivering before the Society a second lecture on Belgian Sculpture. The offer having been gratefully accepted by the Council, this lecture, under the title of "Constantin Meunier et les Sculpteurs Belges de son Temps," was given here on May 6th to a large and interested audience. The kindly service thus rendered to the Society has been recognised by the award to M. Lambotte of the Society's silver medal.

The cost of the Aldred Lectures is defrayed out of the funds bequeathed to the Society by Dr. George William Aldred, in 1868. The series was started in 1908, when the first lecture under the Trust was delivered by Sir William Ramsay, his subject being "A Radio-Active Gas." In 1909 Professor Arthur Dendy gave the Society a lecture on the Principles of Heredity, in 1910 Professor H. H. Turner lectured upon Halley's Comet, and in 1914 Sir Sidney Lee gave a discourse upon Shakespeare's life and work.

VII.—JUVENILE LECTURES.

The success of Mr. Plunket Greene's Cobb Lectures last year on "The Singing of Songs" led the Council to invite him to repeat them in a simpler form for the benefit of a juvenile audience last Christmas. The result was a success quite equal to the previous one. The charming manner in which Mr. Greene is able personally to illustrate his views on the proper treatment of vocal music delighted the less critical, but equally enthusiastic, audience of young people no less than it did the more serious students of musical art who had filled the lecture room a year ago.

VIII. ALBERT MEDAL.

The Albert Medal of the Society for the current year has been awarded by the Council, with the approval of the President, H.R.H. the Duke of Connaught and Strathearn, K.G., to Professor Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S., for his researches in Physics and Chemistry, and their application to the advancement of Arts, Manufactures, and Commerce.

The high value of Sir J. J. Thomson's researches in physical science is widely known and appreciated. There is probably no man alive at the present time who enjoys a higher scientific reputation than he does. The nature of his researches is briefly but adequately summarised in the words of the President of the Royal Society, Sir William Crookes, when

he announced the award of the Copley Medal to Sir Joseph :—

"His early work in the investigation of electrical phenomena showed he possessed a high degree of experimental ingenuity and skill; by his study of the passage of electricity through gases he elucidated the nature of the negative electrical particles, thus providing an experimental basis for the atomic theories of the nature of electricity. His treatise on the Conduction of Electricity through Gases won for him a world-wide reputation as a physicist to which subsequent work has added To him is due the investigation of the nature of the positive carriers of the electric charge; his method of positive ray analysis puts a new and extraordinarily valuable tool into the hands of investigators."

The nature of his work has been such, and so great has been the advance made by it in theoretical knowledge, that there has hardly yet been sufficient time for the application of his discoveries to those practical purposes which it is the special object of the Royal Society of Arts to recognise and to encourage. But the Council cannot doubt that before very long Sir J. J. Thomson's labours will have the same effect upon Applied Science as has been the case with the work of many of his illustrious predecessors, whose names will be found recorded in the list of recipients of the Albert Medal.

IX.—Medals.

The Council have awarded the Society's Silver Medal to the following readers of papers during the Session 1914-15.

At the Ordinary Meetings :—

Sir William A. Tilden, D.Sc., F.R.S., F.C.S., "The Supply of Chemicals to Britain and her Dependencies."

William A. Young, "Domestic Metal Work of the Eighteenth Century."

J. A. Hunter, "The Textile Industries of Germany and of Great Britain."

Hon. John Collier, R.O.I., "Portrait Painting: the Technique of the Great Masters."

Professor W. J. Ashley, M.A., M.Com., Ph.D., "The Economic Position of Germany."

Horace M. Thornton, M.I.Mech.E., "The Industrial Uses of Coal Gas."

A. S. E. Ackermann, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

Charles Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

In the Indian Section :—

Captain Sir George Duff Dunbar, Bt., "Tribes of the Brahmaputra Valley."

Lieutenant-Colonel A. C. Yate, "The Indian Army."

Perceval Landon, "Basra and the Shatt-ul-Arab."

Sir Charles H. Armstrong, "Indian Trade and the War."

In the Colonial Section :—

Major E. H. M. Leggett, R.E., D.S.O., "The Economic Development of British East Africa and Uganda."

Edward R. Davson, "Sugar and the War."

Of recent years it has been the practice that no medals should be awarded to readers of papers who had previously received medals from the Society. Acting on this rule the Council were precluded from considering the following papers:—

At the Ordinary Meetings :—

Sir William de Wiveslie Abney, K.C.B., D.C.L., D.Sc., F.R.S., "Testing Pigments for Permanence of Colour."

William Reginald Ormandy, D.Sc., F.C.S "Britain and Germany in Relation to the Chemical Trade."

John W. Gordon, K.C., "Patent Law Reform and the War."

Lady Lugard, "The Work of the War Refugees' Committee"

T. Thorne Baker, "The Industrial Uses of Radium."

In the Indian Section :—

Dr. F. Mollwo Perkin, F.I.C., F.C.S., "The Indian Indigo Industry."

The Council, however, desire to express their high appreciation of these papers.

The Council have also awarded a Society's Silver Medal to M. Paul Lambotte, Directeur des Beaux Arts au Ministère des Sciences et des Arts de Belgique, for his lecture delivered before the Society on "Constantin Meunier et les Sculpteurs Belges de son Temps."

X.—Owen Jones Prizes.

After the death, in 1874, of Owen Jones, a committee was formed to collect subscriptions for the purpose of founding a memorial, and the balance (a sum of £400) was presented to the Council of the Society of Arts upon condition of their expending the interest thereof in prizes to "Students of the Schools of Art who, in actual competition, produce the best designs for Household Furniture, Carpets, Wallpapers and Hangings, Damask, Chintzes, etc., regulated by the principles laid down by Owen Jones." The prizes have now been awarded annually since the year 1878 on the results of the annual competition of the Science and Art Department, and its successor, the Board of Education.

Six prizes were offered for competition last year, each prize consisting of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's Bronze Medal.

A list of the successful candidates has already appeared in the *Journal*.*

The examiners who judged the works submitted for competition report:—

"The general level of merit is higher than that of last year, and a greater variety of treatment is shown throughout. The principles laid down by Owen Jones have been carefully observed, while the individuality of the students has not been fettered by their observance. Among the best examples submitted are designs for woven silks, wood-carving, machine-made lace curtains, cotton prints, stencilled fabrics, illumination, and pottery."

As already announced, the next award will be made in the current year. Six prizes have been offered for competition.

XI. Stock Prize.

In 1781 John Stock left £100 Consols to the Society, with the condition that the interest should be applied for the promotion of drawing, sculpture, and architecture. So long as the Society gave premiums in Art, the "Stock Medallion" was awarded for architectural designs and for sculpture. In more recent years various awards have been made under the Trust. Since 1893 a prize has been occasionally offered, as the accumulated funds permitted. The last award was in 1908.

A Gold Medal, or a prize of £20, was offered last year for competition among the students of the Schools of Art at the annual competition for a design for the best set of designs for an architectural decoration for the interior of a building, to be carried out in painting, stucco, carving, mosaic, or any other process.

The prize was awarded by the Council, on the report of the examiners in the National Competition of the Board of Education, to H. C. Harvey, of the Hackney Institute School of Art.†

XII.—North London Exhibition Trust.

For some years past the interest on the sum of £157, the surplus of the North London Exhibition held in 1864, has been devoted to the award of prizes to students of the Artistic Crafts Department in the Northampton Polytechnic Institute, Clerkenwell. At present an annual sum of £5 is placed at the disposal of the Governors of the Institute. This year four prizes were awarded in the senior section of the Department (one of £2, one of £1, and two of 10*s*.) and two of 10*s*. in the junior section. The awards were made on the recommendation of Mr. Alan S. Cole, C.B.

The names of the successful candidates have already appeared in the *Journal*.*

XIII.—Examinations.

A very important change was made this year in the arrangements for the examinations. Instead of holding the examinations at a single stated period in the year, two dates were fixed, one in March and one in May, at either or both of which any examination authority or local examination committee could hold its examinations.

It has long been felt that, especially as regards the higher grade examinations, the usual date in the early spring was inconveniently early for many educational authorities. When the classes in many subjects are continued up to Whitsuntide, it is obviously undesirable that an examination in those subjects should be held in March or April; the candidates' preparation is incomplete, and naturally it is difficult to induce students to resume their work after the examination has been held. On the other hand, this does not appear to apply with equal force to the elementary stage. The educational session ends sooner, and for various reasons the earlier date is more acceptable. Inquiries made a few years ago of some of the principal examination committees did not elicit a very definite opinion one way or the other; but the offer made by the Society to hold the examinations twice instead of once a year, which was submitted last year to the Education Department of the London County Council, was favourably considered and eventually approved by the Education Committee, but with the stipulation that the Committee should not be asked to superintend two full examinations. Therefore the original proposal was modified, so far as London was concerned, to the extent that the elementary examinations should be held before Easter, and the examinations in the two higher stages about Whitsuntide. This proposal was

* See *Journal*, July 10th, 1914, Vol. LXII. p. 729.

† Some further information about the prize and its founder will be found in the *Journal*, August 14th, 1914, Vol. LXII. p. 817.

* See *Journal*, April 16th, 1915, Vol LXIII p. 489.

also accepted by the principal independent London institutions who send candidates to the examinations. With regard to the rest of the country, it was evident that it would be difficult, if not impossible, to ascertain the views of all the educational authorities, and it was also tolerably certain that they would be divergent.

It was therefore decided that in the provinces the whole of the examinations in all stages should be held twice in the year, the date for the first examination in 1915 being fixed for March 22nd to 31st, and for the second examination May 10th to 19th. Notice to this effect was sent out to all the examination centres in July, 1914. Outside the administrative County of London, therefore, it was open to any authority to hold its examinations in any subject of any stage, either in March or in May, or at both dates if thought desirable. In London the elementary candidates were examined in March, and those of the two higher stages in May. It is satisfactory to be able to state that the new arrangement was greatly appreciated and worked with perfect moothness. The holding of two examinations in place of one caused considerable extra cost to the Society, and involved some additional labour on the part of the Society's staff, but it is certain that the change has been a useful one, and that it has been highly approved.

The arrangements for next year are under consideration, and will be announced at the earliest possible date.

Certain alterations were made in the syllabuses for various subjects. These alterations were intended to meet as far as possible the views believed to be held by the teachers of classes in those subjects.

No new subjects were added, but Accounting and Banking were separated, and now form two subjects instead of being combined in one. Company Law has been made into a separate subject instead of being included in Commercial Law. Commercial History was separated from Commercial Geography, and forms a separate subject under the title of Economic History.

Certain other alterations in the syllabuses were made, especially in the modern language subjects. In all these subjects certificates are now granted in the two lower stages on a general knowledge of the language alone. In Stage III. the candidates will be expected to specialise to a certain extent, and must show a literary, technical, commercial, or scientific knowledge, as well as a good general knowledge of the language.

For some years past the Society has expended a good deal of money in trying to encourage the study of the less popular languages, and has held examinations in Russian, Danish and Norwegian, Hindustani, Japanese, Chinese, Arabic, Swedish and Dutch. The old rule was that no examination would be held in any subject for which less than 25 candidates presented themselves, but this regulation was ignored in the hope that the numbers would increase if the study of the languages could be rendered more popular. As a result, taking the last six years, only 216 candidates entered, at a cost of about £350, and this, after deducting the £27 paid by the candidates in fees, meant a net loss of £323, or say £1 10s. per candidate. It was therefore determined to enforce the strict rule, and in consequence no examination was held this year in any foreign language, except French, German, Spanish and Italian.

The total number of entries for this year's examinations was 32,113 a falling-off of 5,861 as compared with last year, when there were 37,974 entries. Of these there were 14,427 in the March examinations, and 17,686 in the May examinations. The falling-off amounted altogether to 15 per cent. In the County of London there was a deficiency of 28 per cent. In the provinces generally the deficiency was only 11 per cent.

Naturally when the scheme for holding two examinations instead of one was first decided upon, it was anticipated that the result would be a considerable growth in numbers, and it may be considered as absolutely certain that the replacement of this increase by a deficiency is entirely due to the war. So far from a falling-off being surprising, it may fairly be said that much greater losses might reasonably have been anticipated. It is to be remembered that a large proportion of our male candidates in the two higher stages are of military age or just below it; and, further, that as a larger amount of overtime is now being worked candidates have no time to attend evening classes. So far as has yet been ascertained, the falling-off in such classes, especially those principally supported by young men, has been very great. In some of the large London Polytechnics the numbers of students this year are as much as 40 per cent. below those of last year; and in the London County Council Commercial Institutes, which supply a considerable proportion

of the London candidates, there has been a diminution of about 30 per cent.*

It was always a source of complaint that candidates had to wait a long time before they could know the results of their examinations. A new system of publication of the results of the examinations has been started this year and has been much appreciated. The candidates fill in a counterfoil attached to the paper on which they do their work; on these counterfoils the result of the examination is marked, and they are returned to the centres as soon as possible. By this means candidates are informed of the result of their examination some weeks sooner than in former years, when they had to wait until all the papers had been reported on and classified and the printed results issued.

The results of the March examinations were sent to the centres concerned, the Advanced on April 24th, the Intermediate on May 12th, and the Elementary Stage on June 1st. The examinations were held from March 22nd to March 31st.

The results of the Advanced Stage of the May examinations (May 10th–19th) were issued on June 29th, and those of the Intermediate and Elementary Stages will be sent to the centres as soon as possible.

As soon as all the work of examining the papers and classifying the examiners' returns has been completed, the whole of the results will be issued, as in previous years, in pamphlet form.

The usual full report on the year's examinations will be published in the *Journal* later.

XIV.—Practical Examinations in Music.

The Practical Examinations in Music were not concluded last year until June 27th, too late for the results to be included in the report of the Council. They lasted for eight days.

The examinations were conducted by Dr. Ernest Walker, M.A., and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards were given, and candidates were asked to select for themselves which of these subjects they chose to be examined in.

* The lately-issued report of the Board of Education, speaking of the effect of the war in diminishing the number of students at institutions supported or subsidised by Government, says: "For the Technical, Art, and Evening Schools it is not possible to give even approximate figures; but a number of the larger institutions have estimated the drop in the number of students owing to the war at points ranging up to 50 per cent., and averaging about 26 per cent."

The standards ranged from easy to very difficult music. For each standard a list of music was given for study, and from this list candidates selected the pieces they wished to sing or play. Candidates were expected to play or sing the pieces which they had prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 249 candidates entered, and of these 244 were examined, a decrease of 29 as compared with the previous year. There were 196 passes and 48 failures.

The following were the subjects taken up - Piano, singing, and violin. 205 entered for the piano, 162 of whom passed; 33 entered for the violin, of whom 31 passed; 6 entered for singing, of whom 3 passed. No medal was awarded.

The examiners reported that the average quality of the candidates for the lower standards was perhaps slightly higher than usual, but a good many entered for the fourth standard without any prospect whatever of satisfying that severe test. In general, rhythmical vitality, clearness of phrasing, and variety of tone-colour were the chief desiderata among the pianists.

It was stated in the last report that the Council had under consideration the question of discontinuing these examinations, and eventually they came to the conclusion that the steady decrease in the number of candidates entering indicated that the examinations were no longer of much practical value, and they therefore decided not to continue them. This decision was announced in the *Journal* in September last.*

Last year's examinations were consequently the last of the series which began in 1879 and has been continued annually ever since for a period of thirty-six years. It was at the suggestion of Dr. Hullah that the Society first established examinations in Practical Music, that is to say, examinations at which the actual capacity of students to play an instrument, or to sing, could be tested. Dr. Hullah acted as examiner from 1879 till his death in 1884, and was succeeded by Mr. W. A. Barrett, who died in 1891. The work was continued by Sir John Stainer, Sir Joseph Barnby, and Mr. W. G. McNaught. In 1895, Mr. John Farmer was appointed, and he continued to act till 1899, when he was obliged to give up the work in consequence of illness, which, at a later date, terminated fatally. Since his death the examinations have been conducted by Dr. Ernest Walker and Mr. Burnham W. Horner,

* See *Journal*, September 25th, 1914, Vol. LXII. p. 919.

who served as Assistant Examiners to Mr. Farmer.

In the first year of these examinations (1879) 117 candidates were examined. This number increased gradually and intermittently to 276 in 1891, and to 395 in 1895. In 1896 certain changes in the system were introduced. No alterations have since been made. In that year there were 376 candidates; the numbers rose gradually to 546 in 1900, and reached 557 in 1904. That is the highest point ever reached. Since that year there has been an almost continuous falling off, until the low number was reached last year of 244.

In the year 1892 the Society offered to transfer these examinations to the Associated Board of the Royal Academy of Music and the Royal College of Music; but the Board would not undertake to carry them on at the low fee charged (five shillings), and nothing came of the proposal. Eight years later, in 1900, the question of continuing these examinations was again raised, and some further communications passed between the Associated Board and the Society, but again without result.

XV.—Viva Voce Examinations in Modern Languages.

Up to the present date twenty-three examinations have been held this year in London and Manchester, but it is doubtful if any more will be arranged before next spring.

At the examinations held up to the present date 453 candidates presented themselves, of whom 379 passed (173 with distinction) and 74 failed. The languages taken up were French, German, Spanish, and Italian. There is a decrease of 175 in the number of entries this year; this is accounted for by the fact that a large number of students from the London Polytechnics have joined the mobilised forces.

The results of previous years are as follows:—

Year.	Number Examined.	Passed.	Failed.
1902	280	202	78
1903	456	324	132
1904	540	375	165
1905	681	502	179
1906	644	469	175
1907	629	476	153
1908	615	467	148
1909	656	506	150
1910	642	495	147
1911	583	463	120
1912	633	516	117
1913	688	573	115
1914	628	492	136

It is satisfactory to note that the standard is well maintained. The reports of the examiners speak favourably of the knowledge evinced by the candidates. It may be noted that many of the unsuccessful candidates owe their failure to faulty dictation work.

These examinations are held at any of the Society's centres where the necessary arrangements can be made, at any date convenient to the local committee. The examination includes dictation, reading, and conversation, and is so arranged as to test efficiency in colloquial knowledge of the language, without laying too much stress on minute grammatical accuracy. Candidates who are reported upon as highly qualified by the examiners receive a certificate of having passed with distinction.

The Examiners are Mr. S. Barlet (London), and M. J. Bazin (Liverpool), for French; Professor H. G. Atkins (London), and Professor A. Johannson (Manchester), for German; Mr. J. M. Villasante (London), and Mr. W. F. Bletcher (Manchester), for Spanish; Mr. Luigi Ricci (London) for Italian.

XVI.—Honorary Royal Fellows.

In response to an invitation of the Council, addressed to him in April last, His Majesty the King of the Belgians graciously consented to allow his name to be added to the List of Honorary Royal Fellows. His Majesty was therefore, under the provisions of By-Law 61, elected by the Council.

His late Majesty King Leopold was one of the first two Honorary Royal Fellows elected in 1876, the other being His late Majesty the King of Sweden and Norway.

The other Honorary Royal Fellows of the Society are: The King of Spain (1905), The King of Norway (1906), The King of Sweden (1908), King Manuel of Portugal (1909), The Emperor of Russia (1909), and The King of Denmark (1914).

XVII.—Alien Enemy Fellows.

At their meeting on October 19th last, the first after the declaration of war, the Council determined to expunge from the List of Honorary Fellows the names of all persons of German and Austro-Hungarian nationality, and this has accordingly been done.

XVIII.—Barry's Picture of "Adam and Eve."

The picture of "Adam and Eve," by James Barry, R.A., which was presented to the Society

in 1834 by Mr. R. H. Solly, and has been on loan at the South Kensington Museum (now the Victoria and Albert Museum) since 1856, has been given by the Society to the National Gallery of Ireland, and has been accepted by the Governors and Guardians of that Institution.

Not much of Barry's work, except the series of paintings in the Society's Meeting Room, is now known to be in existence. There are very few specimens in any of the London public galleries, and these are all portraits. It is therefore very suitable that so good an example of a celebrated Irish painter's work should find a permanent home in the country of his birth.

The "Adam and Eve" was the first picture shown by Barry at the Royal Academy. The Society possesses an etching of the picture by the painter. The title is given on the plate as "The Temptation of Adam." *

XIX. Peter Le Neve Foster Prize.

Mr. Reginald Le Neve Foster has presented the Society with a donation of £140 for the purpose of founding a prize in commemoration of his father, Mr. Peter Le Neve Foster, who was Secretary of the Society from 1853 to 1879. Six generations of Mr. Le Neve Foster's family have been associated with the Society, and the connection extends from 1761, seven years after its foundation, to the present time. The original gift of £100, already announced in the *Journal*,† was made up to £140 so that an annual sum of £5 may be available.

The cordial thanks of the Council were voted to Mr. Reginald Le Neve Foster for his gift, which will help to perpetuate the memory of one who, during a long period of office, was highly esteemed and respected by the members.

XX.—Special War Lectures.

The Council felt that the Fellows would appreciate an opportunity of learning something about recent applications of modern science to purposes of war, and they have therefore arranged with Professor Vivian B. Lewes to give a short course of special lectures during the recess on "Modern Munitions of War." Three lectures will be given on three Wednesday afternoons next month.

The first lecture will deal with "Guns and Propellants," the second with "Mines, Shells, and High Explosives," and the third with "Poison Gases and Incendiary Bombs."

The lectures will practically be open free to the public, provided they apply beforehand for tickets. Fellows of the Society will of course require no tickets, and they can admit their friends personally, or by the usual tickets. Any Fellows requiring further tickets can apply to the Secretary, who can furnish them with any number they may desire for distribution. Tickets will also be issued gratuitously to any persons interested in the subject who may apply to the Secretary.

XXI.—New Council.

In accordance with the By-law regulating the election of new members of the Council, the following four Vice-Presidents retire from office as being the seniors on the list: Lord Sanderson, Sir Westby Perceval, Sir John Wolfe-Barry, and Lord Cowdray. A fifth vacancy was caused by the death of Sir John Lamb, which, as it occurred only in March, was not filled up by the Council. The vacancies caused by the deaths of Sir Charles Fremantle and Sir Owen Roberts were filled up at the time. To fill these five vacancies the Council now recommend the Right Hon. Arthur James Balfour, Sir Alexander Henderson, Bt., Lord Newlands, Major Percy MacMahon, and Mr. Carmichael Thomas. The first three named have not held office before; Major MacMahon retires from the Council; and Mr. Carmichael Thomas's term of office as Treasurer terminates in consequence of his having served for five years.

The four retiring Members of Council are: Colonel H. C. L. Holden, Major Percy MacMahon, Dr. William H. Maw, and Sir Aston Webb. In their places the Council recommend Lord Aldenham, Dr. Dugald Clerk, F.R.S., Sir Robert Perks, Bt., and Mr. James Swinburne, F.R.S. Lord Aldenham and Sir Robert Perks have not previously served on the Council. In place of the retiring Treasurer, the Council recommend Lord Sanderson.

XXII.—Obituary.

No less than three Members of the Council have died during the current year. The first of these was Sir Charles Fremantle, who died in October last. Sir Charles had been on the Council, with only short intervals, from 1895. Despite his age (he was over eighty), he was a very regular attendant, and his kindly nature and singularly charming manners rendered him very popular amongst his colleagues. Sir Owen Roberts died in January, and in him the Society lost one of the best friends and most earnest

* Some further information about the picture will be found in the *Journal*, May 7th, 1915, Vol. LXIII. p. 569.

† See *Journal*, July 24th, 1914, Vol. LXII. p. 769.

supporters that it has had for many years. From 1880 he served in one capacity or another on the Council, with a single interval of a year, and in 1905 he acted as its Chairman. Sir John Cameron Lamb, whose death took place at the end of March, was first a Member of the Council in 1906; in 1910 he became its Chairman. For some time before his death his serious illness prevented his attendance at the meetings of the Society, or of the Council; but, until his health failed, he was a very active and useful member.

Lord Rothschild was a Vice-President from 1901 to 1905, but he had not since been on the Council. Sir Charles Hartley, the eminent engineer, was a Vice-President for three years from 1903. He had attained the great age of ninety at his death. Lord Merthyr, who was then Sir William Thomas Lewis, served as a Vice-President from 1907 to 1909.

Sir Charles Crosthwaite was for the last nine years a member of the Indian Section Committee, and on several occasions he occupied the chair at the meetings of the Section. At the time of his death Mr. George N. Hooper had been a subscribing member for sixty-five years. He was elected at the beginning of 1850, and was the oldest of the Society's members. When the Technological Examinations were established, Mr. Hooper acted as examiner for carriage-building, and on two occasions he read papers on that subject before the Society. Mr. Walter Hunter, the well-known water engineer, read a paper here in the year 1899. Sir James Rankin, who had been a member since 1877, read a paper on "The Duty of the State towards Emigration" in 1883. Mr. R. F. Chisholm read a paper in the Indian Section on the Taj Mahal in 1911.

Mr. Edward Riley was a very old member of the Society, which he joined in 1875. He was eighty-three at the time of his death, and it was some time since he had attended any of the meetings, at which, earlier in his life, he was a frequent attendant. Mr. J. F. S. Gooday was for many years the General Manager of the Great Eastern Railway Company. Mr. William Willett had a good reputation as an artistic builder, but his name was best known in connection with his energetic recommendation of what he termed daylight saving—a proposal for legally altering the proper time during certain periods of the year, with the object of inducing people to make greater use of daylight by earlier rising. Sir Robert Walton had been President of the British Chamber of Commerce in Paris, and took an active part in many matters connected with the welfare of his countrymen in that city. Sir Charles Seely, for many years the well-known Liberal member for Nottingham, had been a member since 1871. Dr. Samuel G. Smith was an eminent American sociologist and criminologist. He was also well known in this country. Mr. H. B. Hederstedt was an eminent Indian railway engineer. Mr. George F. Pollock was for many years a Master of the Exchequer Court and Supreme Court and King's Remembrancer.

Mr. J. C. Powell was a member of the well-known firm of glass-makers. Mr. Henry Maull was one of the first professional photographers, but he had retired from business some thirty years ago. His membership of the Society dated from 1861. Colonel W. B. Bryan was Chief Engineer to the Metropolitan Water Board, having previously held the post of Chief Engineer of the East London Waterworks. Mr. William de Hertburn Washington was a well-known American engineer. He was a descendant of Charles Washington, a brother of George. Mr. Alfred Sang, an engineer of reputation in America, France, and England, volunteered for the Intelligence Corps on the outbreak of the war, but received a wound from which he died in October last. Mr. Alfred H. Baynes was for long General Secretary of the Baptist Missionary Society, and had been a member of the Society for over forty years. Mr. Charles E. Chrimes was a member of the well-known firm of Guest and Chrimes, foundry and general brass works, of Rotherham. Mr. William Ewing was a director of the African Lakes Corporation, and he rendered considerable service in extending British rule over the territories north of the Zambesi. Mr. James Spicer was a member of the well-known firm of paper-makers. Mr. Bernard Le Neve Foster was the seventh son of Mr. Peter Le Neve Foster, for long the respected Secretary of this Society. Major J. A. Travers was a prominent member of the Fishmongers' Company, and an active supporter of the proposed amalgamation of the Society with the London Institution, of which he was a member.

Notices of all the above, and of some other Fellows who have died during the past twelve months, will be found in the columns of the *Journal*.

XXIII.—Finance.

The annual statement of receipts and expenditure was published—in accordance with the usual practice—in the *Journal* last week.

It shows the revenue and expenditure for the financial year ending May 31st last, the assets and liabilities of the Society, its investments and the Trusts standing in its name.

As mentioned in the first paragraph of this report, the Queensland 4 per Cent. Bonds held by the Society were paid off on the 1st of this month. The amount, £1,400, actually realised £1,413 17*s*. In the ordinary course of events this would have been reinvested, but the Council were compelled to utilise this amount as ordinary revenue, and to apply the money in discharge of the Society's liabilities. The deficiency in the Society's income from subscriptions and life contributions, as compared with last year, amounts to nearly £550, and there is also a large falling-off in the receipts from examinations, which only amount to £3,646 10*s*. 6*d*., as compared with £4,320 4*s*. last year. As the expenses of the examinations appear in the balance-sheet as £4,522 2*s*. 7*d*., there is a loss of about £875 on this head. It should, however, be explained that this is not a loss on this year's working, since the receipts are those of 1915, and the amount on the other side represents the payments on the previous year's examination. The receipts, therefore, are diminished in consequence of the reduced number of this year's candidates, while the payments are those incurred for the larger number examined in 1914.

THE CHAIRMAN (Colonel Sir Thomas Holdich, K.C.M.G., K.C.I.E., C.B., D.Sc.), in moving the adoption of the report—which he considered most excellent and drawn up with very great care by the Secretary—thought that it was, on the whole, certainly encouraging and satisfactory. He wished to draw the attention of the Fellows to the fact mentioned in the report that the Society had as much as £20,000 reserve capital to fall back upon in such times of stress, which spoke exceedingly well for the careful manner in which the Society's finances had been nursed. He also observed that the accumulation began at the time the present Secretary came into office, and this was one of the many services for which they had to thank their Secretary, Sir Henry Wood. The difficulties which the Society had to face were caused by the war, and he particularly wished to call the attention of the Fellows to the paragraph at the commencement of the report, in which it was stated that, although the Society had not suffered as much as was anticipated during the year, which was a matter for congratulation, yet after the war was over and normal conditions were re-established, we should have a certain amount of leeway to recover, and that unless the Fellows made up their minds to support the Society, it might have to face a period of insufficient revenue, inadequate resources, and impaired efficiency. He felt that the Fellows were quite as capable as himself of judging what the effects of the present crisis were likely to be in the future as regards the prolongation of the war. It was, therefore, incumbent upon all the Fellows to do their utmost to support the Society, not only individually, but also in obtaining new Fellows. The Council had been endeavouring that the Society should, by means of its lectures and other work, take some part in matters connected directly or indirectly with the war, which he thought was entirely as it should be. He did not think the Society could expect practical assistance from the public unless some such measures were taken, and partly for this reason the special course of lectures on War Munitions by Professor Vivian Lewes, had been arranged for delivery in July. He anticipated that these lectures, which were open to the public, would attract very great attention. He was very glad to think that it had been possible for the Society to adopt some method of ventilating matters connected with the war, which would appeal directly to the public.

SIR STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., had the very greatest pleasure in seconding the adoption of the report. He also wished to add that the report was one of the best he had read during his twenty years' connection with the Society, and he had found it exceedingly interesting. He commended to the notice of the Fellows what the Chairman had stated with regard to the position of the Society after the war had ended. He also considered that the functions of the Society should be adapted as far as possible to the subject which was in all our minds—that of the war, and he congratulated the Council on having arranged for the special War lectures by Professor Lewes.

After the CHAIRMAN had pointed out that the report was open to discussion by the meeting, the adoption of the report was agreed to.

THE CHAIRMAN proposed a cordial vote of thanks to Sir Henry Trueman Wood (the Secretary), Mr G. K. Menzies (the Assistant Secretary), Mr. S. Digby (the Secretary of the Indian and Colonial Sections), Mr. George Davenport (the Chief Clerk), and Mr. J. H. Buchanan (Accountant), and to the other officers of the Society for their services. It hardly seemed necessary, he said, for him to say how much they were all indebted to Sir Henry Wood and the other officers of the Society for the careful attention they had given to the affairs and interests of the Society, and for the successful way in which the business of the Society had been conducted throughout the past year. He thought the Society was exceedingly fortunate in having had

the ripe experience of Sir Henry Wood to steer them through their present difficulties.

THE SECRETARY returned thanks for this expression of continued confidence in himself and in the other officers of the Society. He said he naturally felt some sorrow that when the time of his term of office as Secretary was drawing to a close the Society would not be in the same prosperous condition as it had been for some time past. The fact, however, had to be faced that the Society was entering upon a period of lean years, after the comparatively fat years he was thankful to say it had enjoyed during the past twenty-five years. But we all hoped that the bad times would soon pass away. The Society during its long career had had its bad days as well as its good, and he could see no reason why, after the war was over and people had time again to think of arts, manufactures, and commerce, it should not be as prosperous as ever it was.

The ballot having remained open for half an hour, and the scrutineers having reported, the CHAIRMAN declared that the following had been elected to fill the several offices. [The names in *italics* are those of members who have not, during the past year, filled the office to which they have been elected.]

PRESIDENT.

H.R.H. The Duke of Connaught and Strathearn, K.G.

VICE-PRESIDENTS.

Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S.
Viscount Alverstone, G.C.M.G., LL.D., D.C.L., F.R.S.
Sir George Ranken Askwith, K.C.B., K.C., D.C.L.
Right Hon. Arthur James Balfour, LL.D., D.C.L., M.P., F.R.S.
Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.
Duke of Bedford, K.G.
Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.
Lord Blyth.
Earl Brassey, G.C.B., D.C.L., LL.D.
Sir Henry Mortimer Durand, G.C.M.G., K.C.S.I., K.C.I.E.
Sir Alexander Henderson, Bt., M.P.
Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.
Lord Inchcape, G.C.M.G., K.C.S.I., K.C.I.E.
Major Percy A. MacMahon, R.A., LL.D., Sc.D., F.R.S.
Sir Henry A. Miers, D.Sc., F.R.S.
Lord Moulton, K.C.B., M.A., LL.D., F.R.S.
Lord Newlands, LL.D.
Duke of Norfolk, K.G., G.C.V.O.
Hon. Richard Clere Parsons, M.A.
Ernest H. Pooley, M.A., LL.B.
Carmichael Thomas.
Professor J. M. Thomson, LL.D., F.R.S.

ORDINARY MEMBERS OF COUNCIL.

Lord Aldenham.
Dugald Clerk, D.Sc., F.R.S.
Alan S. Cole, C.B.
Sir Steyning William Edgerley, K.C.V.O., C.I.E.
Peter MacIntyre Evans, M.A.
Sir Philip Magnus, M.P.
Francis Grant Ogilvie, C.B., LL.D.
Sir Robert William Perks, Bt.
Sir Boverton Redwood, Bt., D.Sc., F.R.S.E.
John Slater, F.R.I.B.A.
James Swinburne, F.R.S.
Alan A. Campbell Swinton, F.R.S.

TREASURERS.

Lord Sanderson, G.C.B., K.C.M.G.
William Henry Davison, M.A.

SECRETARY.

Sir Henry Trueman Wood, M.A.

On the motion of the CHAIRMAN a vote of thanks to the scrutineers was carried unanimously.

SIR PHILIP MAGNUS, M.P., proposed a very hearty vote of thanks to the Chairman, not only for his services in the chair that afternoon, but also for the great attention which he had given to the affairs of the Society during the whole period he had occupied the important post of Chairman of Council. Sir Thomas had always taken the deepest interest in the Society's work, and had been a great help to the Council.

SIR BOVERTON REDWOOD, Bt., D.Sc., F.R.S.E., said he had very much pleasure in seconding the vote of thanks. He felt sure they all fully appreciated the extent of the services of Sir Thomas Holdich, and how much the Society was indebted to him for the active interest he had continuously shown in its affairs. He considered the Society had always been conspicuously fortunate in its Chairmanship, and he should like to be permitted to add that it had never been more fortunate than in the present holder of the office.

THE CHAIRMAN, in acknowledging the vote of thanks, said that not only had it been a great pleasure to him to serve as Chairman of Council, but it had also been a great advantage to him, for although he was getting on in years he was not too old to learn; and he had learned more in the course of the last two years with regard to many and very varied subjects than he could have accumulated as knowledge in any other way.

The meeting then adjourned.

NATAL FISHING INDUSTRY.

In accordance with a desire expressed by the Provincial Council, the Administrator of Natal last year appointed a committee to inquire into various matters connected with the Natal fisheries. The

committee reported in November, recommending the appointment of a Fisheries Advisory Board, and such a Board has now been appointed. The Board considers matters relating to Natal fisheries, and makes its recommendations thereon to the Provincial Government.

The most important matter demanding the Board's attention is the revision of the fisheries laws and regulations of the province, which are in a bewildering condition. A consolidating measure is expected to be introduced in the next session of the Provincial Council.

The efforts of the Board will have to be directed to the opening up of new markets for the industry. The Johannesburg market is by far the most important in South Africa, but fish caught off the Natal coast cannot compete there with fish caught off the Cape. The reason for this is that at the Cape the fish are trawled, but at Durban they are caught by the line, and the latter method is, of course, the more expensive. If fishing-grounds suitable for trawling were discovered off the Natal coast, Natal fish might be expected to enter the Johannesburg market.

In the absence of markets in South Africa to absorb large quantities of Natal fish, the question of curing and canning for export is all-important. According to the Report for 1911 of the Durban Chamber of Commerce, attempts to establish a fish-curing industry at Durban have been made from time to time, but with little if any success. Recently an important fishing concern in South Africa made serious attempts to cure fish in Durban, but found that the treatment employed by them elsewhere could not be applied successfully to Natal fish. The temperature of the sea off Natal is higher than that of the sea off the Cape, and the difference in temperature is reflected in the nature of the flesh of the fish. The Natal fish probably contains less oily substances than the Cape fish. These and many other questions will have to be settled before the rich harvest believed to be awaiting the fisherman on the Natal coast can be gathered in and marketed.

The following is a statement of the fish captured at Durban in the last two years:—

	Quantity			
	lbs	£	lbs.	£
By sea-going craft.	2,399,648	23,717	2,257,191	23,367
By seiners and others	325,701	3,048	322,256	3,108

SUGAR-MILL MACHINERY FOR WEST CHINA.

Some interesting indications are given in a recent report by the American Consul at Chungking as to openings which at present exist for the supply of sugar-mill machinery in West China. He states that large quantities of sugar-cane are grown in West China, one variety of which—reddish-purple in colour and 5 to 8 ft. in height, with a diameter of 1 to 1½ in.—is sold in its natural state for chewing, being succulent and of excellent flavour. The crop is harvested in November, but the canes are buried in such a way that they keep for many months, and are taken up and sold according to the market demand. The cane from which sugar is made is known as white cane, and is considerably taller, though of smaller diameter, than the red variety. It is very rich in saccharose, and is a most important crop in the Neichiang and Tzechow districts. This cane also ripens in November, but is frequently seen in the fields as late as February.

The apparatus used in extracting, evaporating, and refining the cane juice is exceedingly primitive. The cane is passed between stone rollers turned by water buffaloes, the juice being collected in a large vat underneath the rollers, and conducted to a tank connected with the evaporating plant. The evaporating equipment consists of large iron pans of local manufacture heated by a coal furnace, coal being abundant and cheap in the sugar-growing localities. The first process of refining consists merely in removing the scum that gathers on the top of the liquid. After the juice is partially evaporated it is allowed to cool, and is then ready to be placed on the market as "brown sugar"—a viscous mass quite different from the article known to the Western market as brown sugar. It is not only consumed locally in large quantities, but is also shipped to other provinces. What is known as white sugar is manufactured from brown sugar by further refining and by bleaching in the sun. This sugar is much superior to the brown, and is about twice as expensive. There is no doubt that present manufacturing methods could be much improved. A greater recovery of juice per ton would follow the installation of modern crushers, and a much higher grade product would result from the employment of better methods of evaporation, and the introduction of lime and charcoal in the refining processes.

The Chinese sugar producers themselves realise the necessity for obtaining up-to-date machinery. Just prior to the recent revolution several of them combined and sent a delegate to study sugar-growing and manufacture in Formosa. Unsettled political conditions, however, seriously interfered with their arrangements, and the plans were temporarily abandoned. Now that the situation is more settled, there is a reviving interest in the project of purchasing a complete sugar-mill

equipment. This is especially true of the three important sugar-growing centres of Neichiang, Tzechow, and Pachow.

What will first be needed at Tzechow is a centrifugal equipment for making brown sugar, the plant to turn out about 10,000 lb. a day; an evaporator and a crusher of corresponding capacity will also be needed. While there are no individual producers who are at present doing business on this scale, it would be possible for several of them to unite for this purpose.

Manufacturers of sugar-mill machinery should keep two points in mind if they desire to supply equipment to West China. The field is sufficiently important to warrant the sending of a personal representative here; if it is not practicable to send such a man from home some one sent by an agency in Shanghai could canvass the situation. Convincing explanations are very difficult to make by mail, especially to Chinese, who are unfamiliar, except in a general way, with the needs of the industry. British and German firms are ready to solicit trade through personal representatives, and this means has proved to be the most effective.

It is equally important to remember that first orders should be accepted on as favourable terms as possible. A sufficient amount of machinery can be sold later to offset any loss on the first order, and those who secure the first orders are likely--especially in China--to get the rest of the business.

THE SILK INDUSTRY IN BULGARIA.

The silk industry in Bulgaria may be said to be in its infancy, for it was not until the country had thrown off its allegiance to Turkey, in 1908, that any organised attempt was made to encourage the rearing of the silkworm.

From its geographical position, Bulgaria is pre-eminently a favoured region, the climate is dry and warm, and, excepting in the high mountainous districts, the mulberry tree flourishes everywhere, even at an elevation of more than 3,000 ft. above the sea-level.

In the southern provinces the cultivation of the mulberry tree and the rearing of silkworms are among the principal occupations of the inhabitants.

The cultivation of this tree, which, under Turkish rule up to 1908, scarcely covered an area of 1,600 hectares (3,952 English acres), had almost doubled by 1912.

The Government is doing its best to encourage the extension of the mulberry plantations by the gratuitous distribution of seed amongst the landowners and peasantry.

Instruction in the art of silkworm rearing is given in all the agricultural schools throughout the kingdom. Special instruction, both practical and theoretical, is given at the three principal centres of sericulture, namely, Sadovaj, near Philippopolis, at Orhanic, and at Vratza, a town to the north of Sofia, where a school of practical weaving also has been established.

The mulberry tree is generally grown in special plantations. The trees are usually grown as standards on a single stem, one metre in height. They are sometimes grown as shrubs, with a number of stems branching from the roots. They are usually planted at regular distances of about 2 metres (6 ft. 6 in.) apart. The ground is generally cultivated and planted with maize, potatoes, and garden crops, beneath the trees during the first four years. The trees are also grown, as in Italy, in the open fields, in vineyards, and on the sides of roads.

Generally speaking, the rearing of silkworms, as yet, in Bulgaria leaves much to be desired as regards cleanliness and hygiene, and in some cases is very primitive. Where rational systems are adopted, as in Japan, the cocoons produced are of first-class quality, whilst the others are poor and dirty and consequently fetch lower prices. By existing law in Bulgaria, all "seed" (eggs) used for hatching the worms must be prepared by the Pasteur method, and eggs so prepared may be imported from other countries, especially from France, Italy and Turkey.

According to the latest available statistics, Bulgaria imported in 1911 from

Italy	269	kilogs, to the value of	35,836 francs.
France	346	,, ,, ,,	46,168 ,,
Turkey	21	,, ,, ,,	2,800 ,,
Total	636	,, ,, ,,	84,804 ,,

= 22,430 ounces (avoirdupois) . . . £3,392.

The quantity and value of silkworms' eggs imported every year seem to be decreasing, as shown by the following figures:—

	Kilogs.		Francs.	£ Sterling
1907.	724	to the value of	127,985 =	5,119
1908.	723	,, ,,	106,678 =	4,265
1909.	583	,, ,,	64,171 =	2,586
1910.	497	,, ,,	61,085 =	2,443

The climatic conditions in the southern parts of Bulgaria are more favourable than the north for the rearing of silkworms and the production of mulberry leaves.

The eggs produced from the white cocoons give a larger yield than those from the yellow, being at the rate of 60 kilogrammes (132 lb.) of silk cocoons per ounce of eggs for the first and only 40 kilogrammes (88 lb.) for the second.

The chief kinds of silkworms' eggs in demand in Bulgaria are the "White Bulgarian," the "yellow French," from the Department of the Var, the hardy "Salonika" and the "Italian."

The principal markets for the sale of cocoons are at Vratza, Stanimaca, Hazmanli, Sofia, Gumulgina and Ortakeni.

The silk-reeling industry, which, previous to the last two wars in the Balkans, was but little developed, may now be said to be almost extinct. In Old Bulgaria, at Stanimaca, there was one establishment with 80 reels, which

has been closed for the last two years. The same may be said for another at Sofia (New Bulgaria), belonging to an Italian firm, with 40 reels, and also one with 80 reels at the same place.

The principal causes of the depression of this industry in Bulgaria must be attributed to the general state of unrest in Europe, and the low prices which prevail generally on the silk markets of the world.

The imports of manufactured silk goods to Bulgaria tend to increase, and the value of these goods imported in 1911 from the following countries amounted to:—

	Francs
Austria-Hungary . .	90,384
Switzerland	183,874
France	111,411

WATTLE-BARK SUPPLIES OF BRITISH COLONIES.

Certain tanning materials, such as wattle-bark, in ordinary times find on the Continent their chief markets, which are now closed. Large supplies of the bark are therefore available. They are needed in the United Kingdom, which usually imports large quantities of vegetable tanning materials from the Continent.

Wattle-barks are derived from several species of acacia, which are indigenous to Australia and have been introduced into south and east Africa. The production of wattle-bark is an industry of the greatest importance to South Africa, especially to the province of Natal, and, according to a recent report by the United States Consul-General at Capetown, is rapidly increasing in magnitude. The following table shows the exports of wattle-bark from the Union of South Africa and the approximate average price, per long ton of 2,240 lb. for chopped bark in London from 1909 to 1913 inclusive. The figures show that the price has gradually declined as supplies increased:—

Years	Tons.	Price per ton
1909 . .	36,771	£8 10*s*. 0*d*.
1910 . . .	41,344	£8 2*s*. 6*d*.
1911 . . .	49,645	£8 7*s*. 6*d*.
1912 . . .	52,776	£7 5*s*. 0*d*.
1913 . .	65,052	£7 5*s*. 0*d*.

At the close of 1913 the English market prices for bark were about £7 per ton for "fair average quality," and about £4 19*s*. per ton for poorer quality. The price on October 29th, 1914, was £7 15*s*. for chopped bark.

The following statement shows, in hundredweights of 112 lbs., the exports of tanning bark from the Commonwealth of Australia to the principal countries of destination during the years 1911, 1912 and 1913. The term "tanning bark" includes barks other than wattle-bark, so that the exports of wattle-bark cannot be exactly stated.

Countries	1911	1912.	1913
	Cwt	Cwt.	Cwt
Germany .	148,490	49,849	58,011
Belgium .	29,100	10,180	36,250
New Zealand	65,677	63,310	45,013
Other Countries	9,107	4,349	5,078
	252,374	157,688	144,352

The Chairman of the Wattle Growers' Association in British East Africa states that over 12,000 acres have been planted with wattle in that Protectorate. According to the local Department of Agriculture, the extent of the plantations ready to be harvested for bark is not yet large, but during the next two years the annual output is expected to amount to about 7,500 tons.

Extract.—The average amount of tannin in commercial wattle-bark is 32 per cent. Thick wattle-bark is almost invariably richer in tannin and of better colour than thin bark, and realises better prices.

The material is chiefly used in Germany for the production of heavy leathers, but it furnishes a full, soft leather with calfskin, and might well be used for the production of light leathers.

Leather tanned with wattle-bark has a faint reddish tinge, and the colour darkens slightly on continued exposure to light, but not more so than that of leather tanned with oak or hemlock bark or extract.

Concentrated tanning extracts are now being increasingly used in place of barks and other tanning materials in their natural condition. This fact is recognised in South Africa, where a factory for the manufacture of a solid extract from wattle-bark is being erected and equipped.

GERMAN EXPORTS TO RUSSIA BEFORE THE WAR.

Previous to the war, Russia was the great market for every description of goods "made in Germany."

A few extracts from an article in the *Ruskoie Slavo*, reproduced in an Italian paper for the benefit of manufacturers in that country, will give some idea of the magnitude of the trade that it is proposed to capture.

Amongst some of the most important branches may be mentioned agricultural machinery and implements, amounting to 4,344,000 puds* (70,064 English tons) of the value of 11,744,000 roubles (£1,249,362) annually. Of this, from 32 to 85

* The Russian pud = 36·12 English lbs. = about 62 puds to the English ton. Rouble = about 2*s*. 1½*d*., or 9·4 roubles = £1 sterling

per cent. was imported from Germany. Of the 28,450,000 puds (458,871 tons) of phosphates and other fertilisers imported annually by Russia to the value of 9,809,000 roubles (£1,085,639), the percentage from Germany varied from 29 to as much as 96.

Of iron and steel manufactures, of which 11,481,000 puds (185,177 tons) to the value of 21,086,000 roubles (£2,243,191) are imported, the percentage of German make ranged between 43 per cent. and 95 per cent. Of cutlery, needles, locks and other ironmongery goods, of which 786,210 puds (12,680 tons) are imported to the value of 2,833,000 roubles (£301,388), from 71 to 99 per cent. were supplied by Germany.

Of copper and its alloys, amounting to 786,210½puds (12,680 tons), of the value of 11,645,000 roubles (£1,238,830), the percentage ranged between 54 to 90 from Germany.

Of textile materials to the value of 22,407,000 roubles (£2,383,723), 58 to 94 per cent. came from Germany.

Of electrical machinery, etc., 605,700 puds (9,770 tons), to the value of 15,098,000 roubles (£1,606,170), the percentage imported from Germany ranged from 86 to 96 per cent

ARTS AND CRAFTS.

Stained Glass.—Stained glass was one of the earliest crafts to be affected by the renewal of interest in the applied arts. After langu shing for a long period, it awoke to find itself of primary importance in the days of the Gothic Revival. That was, perhaps, an unfortunate moment for its resuscitation, for it was many a long day before anything was commonly expected or even tolerated in stained glass but a rather servile imitation or adaptation of Gothic models. The considerations of archæology rather than of art were regarded as of paramount importance, and what was demanded of the worker in stained glass was, for the most part, not that he should produce work in which there was any life, but that he should conform carefully and rigorously to precedent. He was asked to be content to do what had been done before. The prevailing passion for Gothic had, however, one great advantage, the good results of which have lingered to the present time. It turned the eyes of the artist in stained glass away from the heavy, muddy, and altogether unglasslike painted work of his immediate predecessors, towards the brilliant, jewel-like glass of the Middle Ages, which relied for its beauty on the quality of its pot-metal glass and the skill with which the glazing was designed rather than on the dexterity of the painter. Again, though the greater part of the nineteenth-century glass was perforce produced in strict conformity to tradition, the work of Morris and Burne-Jones and a few less well-known artists accustomed the public in time to the idea that the art of stained-glass making was a living craft with lessons to learn, not only from the past but also from the present. It cannot be said that the old conditions have entirely passed away. There is still a demand for windows "in the style of the church," which, being interpreted, too often means designed on a stereotyped plan; but for all that there is an increasing understanding of the fact that good work must be more or less original, and that it is not necessary that a window, to be in keeping with, say, a fourteenth-century church, must be schemed exactly as a glassworker of that period would have designed it. There is a growing feeling in favour of entrusting the design and execution of stained glass windows to artists rather than to manufacturers, and there are, further, striking instances of firms whose work is, much of it, not only adequate but even distinctive and original. The increase of freedom of design, moreover, has led to greater rather than less appreciation of the qualities of glass, and though at times the stained-glass designer—who, it may be, is a painter as well—is led to try for effects which may perhaps be over-pictorial, he does not even then forget the limitations of his material or think that he is increasing the beauty of his work by obscuring the glass with enamel colour.

Mr. Louis Davis's glass for the great choir windows at Dunblane—portions of which have been on view, together with the cartoons, at the Medici Gallery is perhaps rather on the pictorial side, but it is beautifully glassy for all that. The subject chosen was the Benedicite, and it afforded the artist ample opportunity for showing his real feeling and his love of symbolism—and gave him at the same time scope for a beautiful display of colour. The windows as a whole suffered rather from the fact that, owing to their size, they could only be shown in sections, so that it was difficult to realise what would be their effect in position; and, added to that, there was the usual trouble with the light, which made colour gorgeously strong at one hour look almost thin at another; but in spite of all difficulties of exhibition it was easy to see how carefully the colour had been schemed and how well considered was the design. "The green things upon the earth" and the "whales and all that move in the waters" offered a splendid chance, which had been seized and made the most of, for delicate variations of colour, as did also, in a different key, "the ice and snow" and "frost and cold." The red wings of the Seraphim were a gorgeous medley of pot-metal reds, of which the effect was heightened by the happy device of setting the heads an inch or so further back than the rest of the glass. "The Spirits and Souls of the Righteous" and the "Holy and Humble Men of Heart" were very beautifully rendered, whilst the artist's appreciation of the sacramental import of the canticle is very happily conveyed by the introduction of

the Angel of Bread and Wine and the Angel of Baptism and the bird's-eye view of the Heavenly Jerusalem. There is a sincerity and a reverence about Mr. Louis Davis's symbolism which is always delightful. In the Dunblane windows we find these qualities combined with a very real understanding of the glass and the possibilities in the way of colour which it offers. The result is a set of windows of which the artist has every right to be proud.

Hammersmith Arts and Crafts. — Local patriotism in London is a plant of somewhat recent growth, which even to the present day only flourishes in certain localities and, for the most part, in those farthest removed from the centre of town. The days are past, however, when Hammersmith could be considered as on the outskirts of London, and yet the last year has shown that it has a strong corporate life, whilst the recent exhibition at Hampshire House, in Hampshire Hog Lane, has called attention to the fact that the district has for some time past been the centre of a good deal of artistic industry. Everyone knows, of course, that Morris settled in Hammersmith, and that the Doves Bindery and Press have been for many years housed near by. But for the rest, most people have not realised how many of those concerned in art and artistic industry either live or work (or do both) there An exhibition of Hammersmith work, however, which includes bookbinding by Cobden Saunderson; printing by the Kelmscott and the Doves Presses; wood-engraving by the late W. H. Hooper and by Noel Rooke; collotype and letterpress printing by Emery Walker; embroidery by May Morris and the Misses Wright; as well as woodwork by Charles Spooner and Romney Green; metalwork by Edward Spencer and the Artificers' Guild; enamels by Mr. and Mrs. Stabler; and stained glass by Christopher Whall and George Parlby, certainly proves the neighbourhood's right to be considered an important art centre. Nearly all the artistic crafts were represented, and the majority of them in such fashion as redounded to the credit of the exhibitors. No one could go over the quaint old house and look at the exhibits without being convinced both of the value and of the sincerity of the work shown there. The specimen room, furnished throughout with simple hand productions, was artistic without being in the least affected. The tables, the chairs, and the bookcases all suggested usefulness as well as beauty. The only drawback which occurred to the visitor was the price of the exhibits. They were by no means dear for what they were, but they could not, of course, compete in price with machine-made work. They will probably last longer and be cheaper in the end, but that does not decrease the initial cost to the buyer. Many people to whom hand-made furniture and metalwork make a real appeal cannot afford them. There is, perhaps, a still larger class of persons who frankly like change, and therefore are not attracted by the prospect of belongings which will last for ever.

The Hampshire House Club, however, strong in its belief as to the superiority of handwork and of a workshop system which provides different surroundings from those of the ordinary factory, has established dressmaking and wood workshops, and hopes to increase its activities. The shops have not yet had a very long trial, but some of the woodwork turned out was very creditable. The dressmaking and embroidery was a good deal less satisfactory. In view of the excellent work done nowadays by the students in the London trade schools, it seems a little doubtful how far there is scope for ventures of this kind. The Hammersmith people have at least the courage of their convictions, and their woodwork, at any rate, is of a type which deserves to have some success.

Belgian Work at Hammersmith.— Hammersmith's activities are, however, by no means bounded by the production of English work. Side by side with the establishment of what will, it is hoped, be permanent workshops, temporary accommodation has been provided to allow Belgians in this country to follow their own trades. Seven refugees are engaged in woodwork, seven more in bootmaking, and three in embroidery. There was not very much embroidery on view at Hampshire House, and bootmaking can hardly be classed as an artistic craft in the ordinary sense of the term. The woodwork, however, comes under quite a different category. The idea is that it should be sold to Belgians and the proceeds used for repatriation, a plan which is commendable in every way. Of the work itself it is difficult to speak too highly. It does not, of course, as a whole appeal to the prevailing English taste, though the copy of the bench from the town hall at Furnes is an attractive piece of work, and the reproductions of objects at Ypres and Louvain have a certain pathetic interest (apart from their beauty) for Englishmen and Belgians alike; but as the work of Belgians for Belgians it is altogether admirable. The workmanship is sound, the designs good of their kind, and the prices asked reasonable in view of the quality of the work. It is to be hoped that, so long as the workshops are needed, they may meet with the support which they undoubtedly deserve.

GENERAL NOTES.

"Scientific American" Anniversary Number. – The number of the *Scientific American* published on June 5th is a special one — the seventieth anniversary number, the paper having been founded in June, 1845. It contains an interesting

and well-written account of the progress of invention from that year down to the present date. This is given for the most part in ten-year periods, though there are in addition special articles, amongst which are "Transportation on Land and Sea," "The History of the Automobile," "Seventy Years of Civil Engineering," "The Invention and Development of Photography," "Communicating over Great Distances," and "The Patent Office and Invention since 1845." Naturally enough the history is written from an American point of view, and full stress is laid upon the work of American inventors. In some cases, such, for instance, as the invention of the reaping machine, exception might be taken to some of the historical statements. But on the whole the history is very fairly written. For instance, the great question as to the inventor of the telegraph is put fairly enough from the American point of view by saying, "Europeans are not willing to concede to Morse the credit of having invented the telegraph, and Americans are not willing to concede to Europeans the credit of having anticipated Morse." But if full credit is given to Americans, it would by no means be fair to suggest that the great inventors of other countries have been by any means overlooked—Wheatstone, Kelvin, Parsons, Fox Talbot, Marconi, Daguerre, and very many others have their work duly noticed. And only those who have tried their hands at recording the progress of invention in past years know how very difficult it is to ascertain the truth with regard to the early history of almost any invention.

Differential Resonator.—An American Fellow of the Society, Dr. Edward Hunter Murfee, of Brenau College, Gainesville, Georgia, has sent the Society a description of a Differential Resonator invented by himself. The object of the invention is, by means of a tube of adjustable length, to provide an air column of any desired length which will vibrate to a corresponding musical note. The principle on which the instrument works is familiar enough, and it is a well-known experiment to hold a vibrating tuning-fork over a tall vessel, which can be filled up with water until the length of the air column is such that it will take up and reinforce the note given out by the fork. The apparatus consists of a tube fitted with a piston, adjustable by a rack and pinion device. The piston-rod is hollow and terminates in an ear piece. By altering the position of the piston the length of the air column in the tube can be regulated, and its position read. For such purposes as tuning musical instruments, such for instance as a violin, the resonator is set at the point where it responds to a given note, and when the violin string is tuned to give out this note the resonator responds. For detecting musical notes at a distance, the resonator can be adjusted until it responds to the note. There are various other purposes for which the instrument is considered to be available, and for which no doubt it is perfectly well suited.

Dogfish as Food.—Some years ago an article on "The Commercial Uses of the Dogfish" appeared in the *Journal*,* which described three factories then recently established in the United States for converting dogfish into oil and fertilisers. The American Department of Commerce has for some time been investigating the question of using it as a food, and it contemplates making an experimental station at Maine, where the fish will be properly treated and then sent out to the public for food, to see how it is accepted. The Bureau believes that the portions that are not suitable for food might be used for fertilisers, as are the waste parts of other fish; that the skins might be cured for leather, and that such experiments as are necessary might well be made by the Government, by taking over some canning plant or menhaden factory for that purpose. Experiments similar to those proposed for the dogfish have been tried by the Government in regard to the sea mussel, and in Boston a supply was sent to leading hotels and restaurants, and found to meet with excellent favour as a palatable food. The bureau believes it is practically impossible to reduce the number of dogfish by a bounty and rendering works, but hopes they can be turned to a good purpose for food, just as were the halibut and swordfish, which for a long time were looked upon with disfavour, but at last became a prized article of sea food.

Printing Inks.—A great deal of useful information is to be found in "The Composition, Properties, and Testing of Printing Inks," a circular just issued by the Bureau of Standards of the Department of Commerce at Washington. It deals with various oils, pigments, driers, and formulæ for the manufacture of printing inks. The effect of the paper on the ink is also considered: some papers are highly absorbent, in which case the vehicle may be a non-drying oil; while with the coated and non-absorbent papers, such as are used for illustration work, a quickly drying or hardening medium must be used, though it must not dry on the formes or rollers. Actual printing tests under definite conditions are preferred for practically finding the qualities of various inks, because "if the article does all that is required of it, its composition is of minor importance." At the same time analytical tests are obviously useful for ascertaining the causes of trouble in printing, the permanency of pigments, and so forth, and there is apparently room for a considerable extension of such work.

New Tin Smelter in Chile.—A company is being formed in Santiago for the establishment of a tin smelter that would manipulate the raw material obtained from the Bolivian tin mines. The foundry, says the *Review of the River Plate*, would be situated at either Arica or Mejillones.

NOTICE.

SPECIAL WAR LECTURES.

Wednesday afternoon, July 7th; Sir Boverton Redwood, Bt., D.Sc., F.R.S.E., in the chair. Professor Vivian B. Lewes, F.I.C., F.C.S., delivered the first lecture of his course on "Modern Munitions of War." The subject of the lecture was "Guns and Propellants."

The second lecture, which will deal with "Mines, Shells, and High Explosives," will be delivered on Wednesday, July 14th; and the third, dealing with "Poison Gases and Incendiary Bombs," on Wednesday, July 21st, at 4.30 p.m.

The lectures will be printed in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

FOTHERGILL LECTURES.

MOTOR FUELS.

By Professor Vivian B. Lewes, F.I.C., F.C.S.

Lecture I.—Delivered February 15th, 1915.

Two years ago I gave a course of Cantor Lectures in this room in which I dealt with the subject of oil as a fuel, and the enormous demands made upon the fraction of the crude oil that we use as petrol for fuel in our motor vehicles naturally led to my devoting considerable attention to that portion of the subject and the proposals that had been made from time to time to find substitutes which could be made available in sufficient quantity to check the then rapidly rising price of petrol, which threatened to bring disaster to the motor industry. Since then considerable work has been done, and my excuse for choosing motor fuel as the subject for the present lectures is as far as possible to bring the subject up to date and to discuss the directions in which the greatest progress seems possible.

Great as had been the increase in the quantities of petrol imported annually into the United Kingdom between 1905 and 1912, the average increase was only about half of that for the years 1913 and 1914, last year's imports reaching the enormous volume of 120,000,000 gallons in spite of the disturbing influence of the war—a great tribute to the work done by our Fleet in keeping open the seas, most of our supplies coming from the Dutch East Indies and America.

The rate of increase in the demand for petrol is so true an index to the growth of motor traction that it is interesting to tabulate the amount imported during the last ten years:—

Year.	Gallons.	Year.	Gallons.
1905	18,000,000	1910	55,000,000
1906	25,000,000	1911	70,000,000
1907	34,000,000	1912	80,000,000
1908	40,000,000	1913	101,000,000
1909	53,000,000	1914	120,000,000

It is then seen that in the six years since 1908 the use of petrol has been trebled. Moreover we must remember that in the last two years, which have shown the most rapid increase in the consumption of petrol, there has been also a considerable volume of benzol, shale spirit and other substitutes employed, which would probably bring the consumption for each of these two years to another 10,000,000 gallons.

It might be supposed that the increase in quantity during 1914 was dependent largely on the enormous volumes of petrol used in the war for transport, aviation and other purposes, but

this idea is negatived by the fact that up to the middle of August the imports of petrol were 80,000,000 gallons, and therefore no sudden increase in supply has manifested itself due to war demands: whilst it must be remembered also that these quantities do not include the Government supplies, which in 1914 amounted to 170,000,000 gallons, chiefly no doubt fuel oil, but also probably partly petrol. All the French ports have been open for the importation of petrol; and it is known that in October France imported 2,250,000 gallons as against 800,000 in October, 1913, so that probably most of the spirit used at the front went direct into the country.

The titanic struggle which is convulsing Europe and sending its tremors over the whole world has demonstrated to the utmost the importance of the motor in war as giving mobility to the troops and keeping up communications between the base and the front, and large as were Germany's stores of petrol at the commencement of the war, Russia's conquests in Galicia and the cessation of supplies from Roumania have cut off the chief means of replenishing them; the pinch is beginning to be felt, and may indeed play a by no means unimportant part in bringing the war to a conclusion.

Enough petrol must be kept for aviation, and it must be as light a spirit as possible; benzol is dangerous to use owing to its crystallising at low temperatures, so that at great altitudes any failure in the warming of the whole of the feed system by the exhaust might lead to the stoppage of a feed-pipe and bring down the machine, whilst in any case light spirit is needed for priming in starting. The forced economy of petrol is already hampering the transport work in the enemy's lines, and benzol and alcohol are being used as far as possible, but in the carbonisation of a ton of coal in the Westphalian coke ovens two gallons of benzol purified sufficiently for this use would be a liberal estimate, so that the problem of motor fuel is a very real one to the enemy, whilst England and France can get all they need from overseas, and Russia can get her supplies from Baku and the other oil-fields on the Caspian shipped direct up the Volga, whilst if more is needed Galician and Roumanian supplies probably would be available. Germany has devoted more attention than almost any other country to the use of alcohol as a motor fuel, and we know that for some years her postal vans were run with it; but the German alcohol is made mostly from potatoes, and the immense demand on this crop for food leaves none available for fermentation.

The crude petroleum as it comes from the oil-well is taken to the refinery and then undergoes a process of fractional distillation, the most volatile portion coming over below 150° C. being called benzine; and before the demand for motor fuel reached proportions so great as to tax the efforts of the producer to the utmost this fraction was again divided by distillation into spirit for dry-cleaning, petrol and solvent spirit, the petrol having a specific gravity of 0·68, and being so volatile that starting troubles were unknown. Now to meet the demand practically all the benzine is sold as petrol, the specific gravity being about 0·72, with the result that starting from cold on a frosty morning is by no means a simple performance. The amount of this benzine present in the crude oil varies widely with the oil-field, some, like the oils of Sumatra, Borneo, Roumania, Pennsylvania, Kansas and Illinois, containing percentages of from 14 to over 30, whilst the Californian and Texas oils rarely reach 5 per cent.

The chief sources from which our supply has been obtained during the past two years are shown in the following table: —

IMPORTS OF PETROL IN MILLIONS OF GALLONS.

	1913.	
Dutch East Indies	52	
United States .	24	41
Russia . . .	13	10
Roumania . .	6	6
Mexico . . .	1·5	2·5
Other countries .	4·5	3·5
	101·0	120·0

The interesting point about this table is that it shows the enormous increase during the past year in the importation of petrol from the United States, which has made up for the cutting off of the supply from Russia and Roumania since August last, and also that in spite of this the supply from Roumania was so increased during the early months of the year that her total for 1914 is as high as for 1913.

One of the reasons that put up the price of petrol in 1911–12 was the high freights caused by the number of oil tank steamers engaged in

shipping the spirit being inadequate to meet the rapidly increasing demand, and as a result twenty-eight oil-tankers were launched in 1913 from English yards; six of these were of 15,000 tons capacity each, and the total capacity of the new fleet was 250,000 tons. The number of these vessels was added to largely in 1914, with the result that freights have fallen to a point that offers no excuses for inflated prices, and during the last year a reduction was made in the price of the best petrol by one penny a gallon.

Petrol distilled under ordinary conditions from the crude oil consists of a mixture of the first five liquid members of the paraffin series, all of which boil at or below 150° C., and its specific gravity and volatility depend upon the proportions in which these compounds are present.

THE VOLATILE LIQUID PARAFFIN HYDROCARBONS.

	Formula.	Boiling-point.	Specific gravity.
Pentane . .	C_5H_{12}	37°C	0·628
Hexane .	C_6H_{14}	69	0·664
Heptane .	C_7H_{16}	98	0·700
Octane .	C_8H_{18}	125	0·719
Nonane . .	C_9H_{20}	136	0·741

The petrol which was at first imported had a specific gravity of 0·680, and consisted of a mixture of the first three; octane then began to appear in quantity in the spirit, and the specific gravity rose to 0·700; whilst for the last few years nonane has also been present, and the specific gravity has been 0·72 and over. It must not be assumed that all the petrol at present imported consists of these saturated hydrocarbons only, as when we come to discuss the subject of making petrol substitutes by "cracking" heavier grades of petroleum by heat into more volatile ones, we shall find that some of the paraffins, to which series all the above belong, are changed into unsaturated hydrocarbons which, although as volatile, are of a heavier specific gravity, and the demand for petrol has led to many refineries adopting methods of distillation that increase the normal yield at the expense of the heavier portions of the oil, so that it is quite possible to have a petrol of even higher specific gravity than nonane itself, and it is a mistake to suppose that the specific gravity of a motor fuel is any guide to its value. This will be realised when one considers that benzol, which is an excellent motor fuel, has a specific gravity of 0·886, which in a paraffin hydrocarbon would have meant a heavy residual oil of no use as a motor fuel unless used in a Diesel engine.

There is one point, however, on which specific gravity affords useful information, and that is with regard to the weight per gallon, as specific gravity being a comparison of the weight of the liquid with an equal volume of distilled water taken as unity, and as a gallon of distilled water weighs 10 lb., all that has to be done to obtain the number of pounds that go to a gallon of any liquid is to move the decimal point in the figure for specific gravity one place to the right, and the result is the pounds per gallon.

One of the important considerations in comparing the value of motor fuels is the amount of energy that can be stored in the petrol-tank, of which we know the capacity in gallons. On determining the calorific value of various grades of ordinary petrol, the differences between their thermal units are, as a rule, small, as one would expect from the fact that all the series of paraffin hydrocarbons contain hydrogen and carbon in only slightly varying proportions, and as the experimental determination of the calorific value of such highly volatile liquids as petrol is fraught with considerable difficulty, the variations found often reflect this factor rather than any great difference. The average results of experiments, however, in spite of what one would expect from calculation of them, often show a higher calorific value for the lighter grades of spirit, and average out at such figures as—

Specific gravity.	B.Th.U. per lb. net.
0·680	18,900
0·700	18,700
0·720	18,500

which would represent fairly the general trend of determinations, and at first sight might give the impression that the lighter spirit was the more valuable. As gauged, however, by the capacity of the petrol-tank, it is heat units per gallon that interest us, and our figures become—

Specific gravity.		B.Th.U. net per gallon.
0·680	18,900 × 6·8 =	128,520
0·700	18,700 × 7·0 =	130,900
0·720	18,500 × 7·2 =	133,200

And for all practical purposes we may take the ordinary petrols on the market that have a specific gravity round about 0·720 as having

a thermal value per gallon of 132,500 B.Th.U. net and 144,000 gross.

The gross heating value of a fuel is the total heat evolved by the complete oxidation of its combustible constituents, whilst when hydrogen is one of these it burns to water, the vaporisation of which renders latent a portion of the heat evolved, and if the steam escapes with the other products uncondensed this heat is lost with it, and the net calorific value of the fuel is the total heat of combustion minus the latent heat of the water vapour formed.

In the internal combustion engine the water formed by the combustion of the hydrogen of the petrol all escapes as steam, so that it is the net calorific value that is the important factor.

In forming an estimate as to the value of a motor fuel, calorific value is by no means the most important thing to consider, as often it happens that the efficiency of the engine using it may be so increased, owing to the nature of the fuel allowing of high compression or other factors that tend to the better conversion of the heat units into power, that a fuel relatively poor in calorific value may be nearly equal to one of far higher thermal units in actual use.

There is, however, one point that always must be taken into consideration, and that is the vapour tension of a liquid intended for use as a motor fuel, as this governs its power of evaporation, and upon it depend ease in starting from cold and flexibility in running.

A good motor fuel must give off enough vapour at low temperatures to form an explosive mixture in the cylinders of a car that has been standing all night in a cold garage, as if it does not considerable time and much effort have to be expended in working the starting gear, so as to get a sufficient amount of combustion in the cylinder to raise it to the necessary temperature.

A good deal naturally depends on the form of carburettor used; but with any of fairly modern type a good spirit should give no trouble.

We have seen that when a crude oil is distilled the temperature is raised gradually, and that the fraction which comes over up to 150° C. is called "benzine," and contains the most volatile portions of the oil. The next fraction coming over at from 150° to 300° C. is called "kerosene," and forms the ordinary illuminating oil. The lower fraction can be redistilled, and if the specific gravities and vapour tensions of these fractions be taken it will be found that the vapour tension falls as the specific gravity rises, as is shown in the following table obtained from the fractionation of an American oil:—

Specific gravity.	Vapour tension in mm. water at 15° C.
0·650	2,110
0·680	1,185
0·695	930
0·735	410
0·756	125
0·762	85
0·772	40
0·788	15
0·812	0

These figures make it clear that an oil of this last character, having a specific gravity of 0·812 (which would correspond to kerosene or lamp oil), cannot be used alone as a motor spirit, because on a day when the temperature was 15° C. the engine if cold would never start, as no vapour would be given off to make the explosive mixture with air, and not only must vapour be given off but sufficient vapour to make an explosive mixture with the air in the cylinder.

The scientific methods of determining the vapour tension of a liquid upon which its volatility depends would be far too complicated for use by the ordinary observer; but he can form an equally sound judgment as to how far a motor fuel is likely to be satisfactory in starting and flexibility by means of a simple apparatus devised by Sir Boverton Redwood and Captain Thomson, whereby the relative volatility of various spirits could be determined, the object they had in view being the pressure the spirit might develop in a closed vessel on increase of temperature as bearing upon safety in storage and transport.

The apparatus consists of a thick-walled glass tube of small bore, about 30 in. long. The lower end of the tube is turned up and widens into a cylinder, about 6 in. long and 1 in. in diameter, the upper end of which terminates in a short length of glass tube. The long tube is graduated in inches divided into tenths, and the wide cylinder is provided with two marks, the lower corresponding with the zero of the scale and the upper being placed at nine-tenths of the capacity of the cylinder above the lower mark.

In use a short length of stout rubber tubing is wired to the tube at the top of the cylinder so as to cover it entirely and project about ¾ in. above it. Mercury is poured into the cylinder up to the lower mark, and care is taken that the mercury thread in the capillary tube is not broken. Enough of the liquid under test is

poured into the cylinder to fill it well up to the upper mark, and the apparatus is clamped vertically in a vessel of water at 50° F. After sufficient time has elapsed to allow of this temperature being attained by the apparatus and its contents, the level of the liquid is corrected, if necessary, and the rubber tubing is closed by a pinch cock screwed up very firmly just above the top of the glass tube, the open end of the india-rubber tube being further closed by a glass stopper. The whole apparatus is immersed above the top of the rubber tube in water at 50° F. The temperature of the water is raised very slowly by means of a rose burner, and its temperature read by means of a thermometer immersed in it, unequal heating being avoided as far as possible by any form of mechanical stirrer. As the temperature of the water rises the height of the column of mercury in the capillary tube is read off at every 5° F. rise of temperature in the liquid, the heat being so regulated that this rise takes about ten minutes, and is continued to 100° F.

In this way a comparison can be made between the vapour pressures of various suggested substitutes for petrol as long as they are of the same kind of hydrocarbon, as we know that the best petrols on the market, such as Pratt's "Perfection," give only just the necessary starting power on a cold morning, and that anything that gives a vapour pressure less than that will give rise to trouble in starting, the pressure being a very fair measure of the trouble that would be experienced.

In the following table are given the pressures exercised by Pratt's "Perfection," benzol, alcohol, and pentane:—

VAPOUR PRESSURE IN INCHES IN MERCURY.

Temperature °F.	Pentane	Pratt's spirit.	Benzol.	Alcohol.	A.	B.
55	1·4	0·7	·1	·3	·4	1·0
60	2·0	1·4	·7	1·1	1·1	2 6
65	3·8	2·6	1·5	1·8	1·9	4·2
70	5·8	3·6	2·5	2·7	2·8	6·4
75	8·0	4·8	3·5	3·6	3·8	8·9
80	10·4	5·9	4·5	4·7	4·9	10·9
85	13·1	7·1	5·5	5·75	6·2	13·4
90	15·9	8·2	6·4	6·9	7·1	15·6
95	18·9	9·3	7·3	8·0	8·1	17·6
100	22·3	10·5	8·4	9·2	9·0	20·5

Taking the figures in the table, we know by experience that Pratt's spirit with an air temperature of 60° F. starts from cold without any trouble, and so also would the benzol and the two cracked spirits marked A and B, but nothing one could do would make the alcohol start at that temperature, although it is showing a higher vapour pressure than the benzol, and this is due to the percentage of combustible vapour in the mixture in the cylinder that will explode with electrical ignition. In the case of the benzol it needs only 2·7 per cent. of vapour to give explosion, whilst with alcohol there must be at least 4 per cent., so that although its vapour pressure is higher than that of benzol it does not vaporise sufficiently quickly to reach the larger proportion of vapour needed.

When petrol or other combustible vapours are mixed with air the maximum of chemical action—that is, the complete oxidation of the carbon and hydrogen of the combustible into carbon-dioxide and water vapour gives the greatest energy of explosion. This point is a fixed and unalterable ratio of the vapour to air, and varies only with variation in the composition of the combustible body. On each side, however, of the percentage of vapour that gives the maximum effect there is a range over which the mixture is still explosive, although gradually diminishing in power the further the percentage of vapour is from the correct mixture, until points are reached above and below which the mixture is non-explosive.

The percentage over which the mixture is explosive is called the "explosive range," and varies slightly according to the method of ignition, and figures that have been given for electrical ignition are:—

EXPLOSIVE RANGE OF AIR-VAPOUR MIXTURES WITH ELECTRICAL IGNITION.

Acetylene	3·2 to 52·2	per cent.	range	49	per cent.
Ethylene	4·2 to 14·5	,,	,,	10 3	,,
Alcohol	4·0 to 13·6	,,	,,	9 6	,,
Ether	2·9 to 7·5	,,	,,	4·6	,,
Benzol	2·7 to 6·3	,,	,,	3·6	,,
Petrol	2·5 to 4·8	,,	,,	2·3	,,

although when ignited by a flame a still smaller proportion is combustible with explosion.

It is quite evident that the wider the range over which the spirit employed will form an explosive mixture, the more elastic will be the proportion of air, and we all know the trouble caused when a sudden change in heavy traffic stops the engine by throwing the mixture outside the explosive limits.

Another test which it is essential to make

with a motor spirit is a fractional distillation, in order to ascertain the proportion of hydrocarbons present in it vaporising at a sufficiently low temperature to ensure a complete combustion in the cylinder, and with spirit of the ordinary character 90 per cent. ought to distil over below 150° C.; but it must be remembered that this does not always apply to petrol substitutes.

In carrying out a fractional distillation of this character great care has to be exercised in standardising the method to be employed, as the results found by various observers in a fractionation of the same spirit differ widely, unless the same method of procedure and apparatus are adopted. Probably the most satisfactory method is to take a short-necked Jena glass flask, into the neck of which is fitted a five-bulb Young dephlegmator, in the top of which is placed a thermometer so arranged that the bulb is just below the level of the side tube. A uniform rate of distillation throughout the run must be maintained, and the temperature is noted at which the first drop leaves the end of the side tube. From that moment the volume collected through each 10 cc. should be noted, and the distillation carried up to 150° C., unless the bulk of the liquid has passed over below that temperature.

When distilling mixtures such as are to be found in some petrol substitutes, the distillation results, if plotted out, will generally give a very good idea of what the constituents are, which can be confirmed by taking the specific gravities of the main fractions. In the following table the fractionation of Pratt's spirit is shown as an example of a true petrol:—

FRACTIONATION OF PRATT'S SPIRIT.

Specific gravity	0·7088	
First drop	30°C.	
Below 50°C.	1·50	per cent.
,, 60°	7·25	,,
,, 70°	19·25	,,
,, 80°	28·75	,,
,, 90°	42·25	,,
,, 100°	57·25	,,
,, 110°	70·25	,,
,, 120°	79·50	,,
,, 130°	86·50	,,
,, 140°	91·00	,,

It must, however, be clearly grasped that in many petrol substitutes it is possible to use mixtures in which some fractions distil as high as 250° C. if sufficient spirit distilling below 100° C. is present to give ease in starting and the necessary flexibility in working.

When petrol was first introduced it seemed probable that its high volatility, and the fact that the vapour it gave off was highly inflammable and formed a violently explosive mixture when mixed with air, might threaten its use, but experience has shown that the accidents due to it have not been nearly so numerous as it was feared they might be. One knows from experience that on a warm summer's day the vapour comes off so rapidly that a tin left open soon undergoes a serious diminution in volume, and that the spirit has such a wonderful penetrative power, and is so liable to creep, that the smallest fault in a screw-cap or plug leads to a slight leakage, with the result that in places where the petrol is stored slight leakage and evaporation into the air are constantly occurring, and as 2½ per cent. of the vapour in the air forms an explosive mixture of maximum strength, whilst 1·6 per cent. is still explosive when ignited by flame, strict precautions should be taken to protect such places from becoming an active source of danger. Probably the factor which gives the greatest danger is that the weight of the petrol vapour is so far above that of air that it spreads and flows over a flat surface in much the same way that a liquid would do, and as a pint of it poured on the floor will give sufficient vapour to cover 80 sq. ft. with inflammable vapour to a sufficient thickness if ignited at any point to carry the flame back to the point of leakage, it is clear that the floor level is the one which should be specially considered in precautions to minimise danger, and a strong floor draught is one of the most important factors of safety that can be provided.

The reason why so few accidents happened in the past is due to the high temperature needed to ignite the vapour either alone or mixed with air, and a long series of experiments made by Sir Boverton Redwood, Colonel Majendie, and Dr. Dupré in the early days of the use of petrol showed that the vapour could not be ignited by the glowing spark on a splint of wood, a red-hot piece of coke, or a shower of sparks from a flint and steel; and from experiments which I have made since I think we may safely assume that the ignition point is in the neighbourhood of 1,200° C., and it is this which has safeguarded its use. How often have we seen the careless chauffeur filling the tank of his car with spirit whilst at the same time smoking a cigarette, a proceeding which, had the igniting point been as low as that of any ordinary combustible, such as paper, wood or coal, would have led to disaster.

The necessary temperature to cause ignition,

although never reached by a glowing body, is attained with the smallest of flames, the temperatures of which are practically all higher than 1,200° C., and the throwing down of a lighted match on a surface over which petrol vapour is flowing has caused many serious fires.

The high ignition point of the explosive mixture of petrol and air also explains the necessity for a higher density spark for igniting the mixture in the cylinder.

The volume of vapour yielded by a sample of petrol depends upon its composition, the variation which exists between the various constituents being shown in the following table:—

VOLUME OF VAPOUR FROM PETROL HYDROCARBONS.

	Specific gravity	Boiling-point.	Cubic feet of vapour. Per gall.	Per lb.
Pentane . .	·626	37·6°C	31·2	4·9
Hexane . .	·664	69°	27·7	4·1
Heptane .	·700	98°	25·7	3·7
Octane . .	·719	118°	22·6	3·1
Nonane . .	·741	136	20·8	22·9

So that the higher the specific gravity the lower will be the gas yield.

In considering the price of petrol we must not lose sight of the enormous amount of handling which it has to undergo from its distillation and rectification until it reaches the consumer. It has to be piped down from the refinery to the port, run into the big tank steamers which bring it to the English ports, and there it has to be unloaded into store; all of which operations with a highly volatile liquid like petrol give rise to a certain amount of loss, and the transport is rendered more costly by the regulations laid down to ensure safety, whilst the tank steamers have to be of special type, and its handling from the moment it reaches this country is hedged around with regulations.

The chief distributing ports in England to which petrol is brought are Thames Haven, Bristol (Avonmouth), Barrow, Manchester, Liverpool, Hull, Sunderland, Cardiff, Plymouth and Southampton, the Thames Haven stores being the most important in the world. And it is here that all the petrol for London and the south-east district is landed, as tank steamers are not allowed higher up the Thames.

At Thames Haven the tank steamers come alongside the deep-water wharves, and the cargo is pumped into great storage tanks, of which there are now over 100, many of them holding 4,000 tons each. The ground occupied has a river frontage of over a mile in length, with a varying depth, two-thirds of which is taken up with the storage tanks. The whole is fitted with a unique arrangement of pipes and pumps, by which the discharging of the cargoes into the storage tanks and from the tanks to the barges, and the various canning and barrelling departments, is carried out, all the pipes being led to an exchange building, at which connection to the loading and unloading piers, the tanks and the various departments can be effected, so that the contents of any tank can be transferred to another or to a pier line or canning department at will—an arrangement which gives absolute control over the whole storage, and allows the handling of the oil to be carried out with the minimum of loss and labour.

From Thames Haven the petrol is distributed either by rail in tins or drums or in bulk by barge to the London stores of the various big companies, at which again elaborate precautions have to be made to ensure safety, and here if canned it has to be distributed to the retailer. The cost of storage and distribution from Thames Haven has been given by Sir Marcus Samuel as 5*d*. per gallon, and the tax amounts to another 3*d*.; so that it is seen that the price of the spirit has been inflated largely by these charges, and that its cost at the point of production must be very low in order to admit of the large profits which undoubtedly are made, and it is these extra charges for distribution which are often forgotten or insufficiently allowed for in considering the price at which various motor substitutes can be sold, and also the influence which any large increase in the cost of freight must have upon the price of the spirit, a factor which was undoubtedly an important one in the rises that took place three years ago.

SCIENTIFIC AGRICULTURE IN BENGAL.

Perhaps no province in India is more suitable in every respect for agricultural experiment and research than Bengal, with its great variety of soils, its damp, hot climate, and its rich deltaic areas. The annual reports of the expert officers of the Bengal Department of Agriculture for the year ending June 30th, 1914, testify to this. The chief points are summarised in the *Pioneer Mail*. Three of the most important crops of India are rice, jute, and sugar-cane. All of these flourish in Bengal, and have throughout the year been made the subject of special study by the economic botanist, the fibre expert, the agricultural

chemist, and the Imperial mycologist. In view of the great progress made in recent years in the development of the Agricultural Department, it is curious to recollect that a short decade ago none of the provinces had an Agricultural Department at all. It was in 1904 that Lord Curzon, with the help of Sir Denzil Ibbetson, took up the question of the thorough reorganisation of the department for the whole of India, which resulted in the establishment of the Imperial Agricultural College and Research Institute of Pusa, and later on of special departments and colleges for the Provinces. How necessary this action was the result has proved. Already great benefits have accrued to agriculture, and the opportunities of the future seem almost inexhaustible.

In Bengal there is a system of agricultural stations or demonstration farms, each farm being under a special superintendent of its own, where important experiments are carried out under adequate supervision It is at these agricultural stations that the fibre expert, the agricultural chemist, and the economic botanist are able to test the theories of the laboratory. There are now agricultural stations or farms at Dacca, Chinsura, Rajshahi, Burirhat, Rangpur, Burdwan, Kalimpong, and Chittagong; so that practically all the divisions of Bengal are represented.

The fibre expert has his headquarters at Dacca, the centre of the flourishing jute trade of Eastern Bengal. Very interesting experiments have been made with regard to manures for jute on red acid soils in Bengal. These manurial experiments were begun in 1911, and the results now obtained confirm those of the previous years in a very convincing manner. The lime applied in 1912 gave an increase of 4 maunds per acre of fibre over the unlimed plots: and in 1913 the same plots without any further application of lime yielded nearly 5 maunds per acre more fibre than the unlimed ones. This shows the great value of lime as a manure on such soils. In addition to this, the fibre expert, Mr. Meggitt, is investigating the effects of various forms of phosphoric acid on both limed and unlimed land. "There seems to be no doubt that the action of phosphates benefits jute to a considerable extent; and there is at least some indication that their application actually tends to increase the percentage fibre-content of the plant --a most important matter. There are also indications of their action in other directions; but further work is required, not only on these points, but also as regards the form of phosphates whose application is most advantageous." How important these investigations are likely to be in their effect upon the production of jute may be gauged by the fact that in three years an aggregate expenditure of Rs. 47 per acre on lime and bone has increased the aggregate yield of jute and mustard on the Dacca plots to the value of no less than Rs. 144, representing an increased net return of Rs. 97 per acre. If a more extensive test corroborates the truth of these inferences, the fibre expert will have great cause for congratulation on the results.

Turning to the report of the economic botanist, Mr. G. P. Hector, we find that special attention was paid to the main food crop of Bengal, namely rice. The Ufra paddy disease is very common in Bengal, and very deadly in its effects on the rice crop. Experiments have been made to test the effect of thorough ploughing and stubble-burning during the cold dry months, and these experiments are being carried on in consultation with Dr. Butler, the Pusa expert. There is good ground for hope that they may supply a remedy for Ufra disease, and it is proposed to extend the tests at Comilla under as careful control as possible. With regard to sugar-cane, some valuable work has been done by Mr. Annett, Agricultural Chemist to the Government of Bengal. Five varieties of sugar-cane were tried on the Dacca farm with the object of finding out the most suitable varieties for distribution to cultivators. The results obtained show that the method of sampling recommended by Dr. Leather, Imperial Agricultural Chemist, gives extremely happy results. This method will be followed in future years, and will result in much saving of time in the chemical control of sugar-cane experiments.

GERMANY'S CHIEF COLONY.

Trade of East Africa for 1912-13.

It is early to predict what the future of Germany's colonial possessions may be at the close of the war, but special interest attaches to the report on the trade, commerce, and economic position of German East Africa, which, owing to its peculiarly exposed situation, seems almost to invite annexation at no very distant date. The trade of the colony in 1912 showed an upward tendency in satisfactory proportion to the general improvement in most economic directions. The white population increased by 470, the area under cultivation by Europeans increased from 217,060 acres in 1911 to 312,422 acres in 1912, and to 407,612 acres in 1913, and considerable progress was made in the development of native agriculture. The railway from Tanga on the coast to Moschi at the foot of the mountain peak, Kilimanjaro, was thrown open to general traffic, and the Great Central Railway from Dar-es-Salaam, on the coast south of Zanzibar, to the terminus of Kigoma, on the eastern shore of Lake Tanganyika, was completed on February 2nd, 1914, and great hopes are entertained for the expansion of the Protectorate's trade in the future from the extension of the railways, as there are still large tracts of thickly-populated and fertile land which await opening up by the introduction of adequate means of transport.

The planters complain that there are too many officials, that they are overburdened with troublesome regulations, and that the Government does not supply them with the workpeople they require. The high tariffs on the railways are a source of

constant and loud complaints from planters, merchants, and farmers, and a sympathetic echo is heard in many official quarters. The value of the total imports amounted to £2,515,455 in the year 1912, and shows an increase of 9·6 per cent. over those of the previous year. By far the greater part of these come in through the coast ports, while rather more than a tenth part enter by the overland routes, chiefly *via* the Uganda Railway and the Victoria Nyanza. The total value of the exports in 1912 was £1,570,915, of which 40 per cent. form the increase over the figures for the preceding year.

The principal ports on the coast are the capital, Dar-es-Salaam, and Tanga, and the value of the trade of the first-named was £1,615,000 in 1912, against £1,310,000 in the previous year. The trade of the ports on Lake Victoria Nyanza showed good development, and complaints were heard in 1912 that neither the steamers on the lake nor the Uganda Railway were able to cope with the volume of the traffic. As regards openings for British trade, it is noticeable that the European population increases but slowly, and up to 1914 was largely composed of Germans. It is therefore to be expected that the imports of goods for European consumption will not increase very rapidly, and that they will be for the most part of German origin to suit local tastes. But the trade in articles for the native market is capable of enormous expansion, and there seems no reason why imports of British goods should not increase very considerably. The Indian community, which has increased by some 4,000 in the last six years, is regarded with extreme dislike by the majority of the white population, and, to judge by the attitude of the Indians themselves, is not invariably accorded a sympathetic treatment by the authorities. As a matter of fact, the Indian is a useful, if not an indispensable, member of the community. He is a pioneer of trade, a clever clerk, and a skilled mechanic. He carries on work which the native is incompetent to perform, and he can do so under conditions of life and with an amount of food and capital which would be utterly impossible for a European.

The Central Railway line, which runs from Dar-es-Salaam to Lake Tanganyika, a distance of 780 miles, was begun in 1905, and reached the lake at Kigoma, near Ujiji, in February, 1914. This will become the main artery of traffic, with branch lines to the north-west, and possibly to the south-west (Lake Nyassa region), and will play a most important part in the development of the trade of the Protectorate and in opening up the Tanganyika district. The great lake appears to be regarded as the key to the trade of Central Africa, and the energy with which the rail has been pushed on enables one to travel in two days and two nights from the coast at Dar-es-Salaam to the lake, a journey which the caravans used to take sixty days in accomplishing. When the short stretch of line of about 170 miles, between Lukuga on Tanganyika and Kabola on the Congo, is completed, it will be possible to travel across Africa, from Dar-es-Salaam to Boma, in about three weeks by rail and steamer, if direct connection at each stage is assured. It is also hoped that the Central line will ultimately handle much of the traffic to and from the eastern portion of the Congo and North Rhodesia.

The area under rubber cultivation in German East Africa increased from 81,705 to 112,257 acres in 1912, and the amount of rubber previously exported with a value of £180,000 doubled that quantity in the same year. A large assortment of equatorial products, including among others cotton, sugar, oil-producing plants, wax, cereals, rice, coffee, tobacco, ivory, and reserves of valuable woods, bid fair to develop to a considerable extent.

TIMBER IN BRITISH NORTH BORNEO.

The Government of British North Borneo is taking steps for a general survey of the timber possibilities of the country, and, for the purpose of estimating the amount available and classifying it into the various kinds suitable for export, Mr. D. M. Matthews, an American forestry expert, formerly in the Forestry Service of the Philippines, has been employed.

According to a report by the United States Consul at Sandakan, Mr. Matthews began his duties in December, 1914, and is now proceeding with the work of classification. It may be said that the entire surface of British North Borneo is covered with forests. On account of the dense vegetable growths of all kinds in the tropics, the word "forest" is seldom used; instead, the word "jungle" is commonly applied.

Large Trees—Rare Hardwoods.

In British North Borneo, however, all that part lying back from the coast, except along the rivers, is covered with forest and not jungle. The trees are large, and the undergrowth of vegetation is not so great as in the low-lying country and in the swamps along the coast. The entire coast-line is an unbroken jungle of nipa palms and mangrove trees, but the higher ground is covered with many kinds of forest trees, particularly rare hardwoods, which it is the intention to convert into timber for export. These hardwoods are of many kinds, and can be used for many purposes

A peculiar feature of several best-known woods is the dual formation—a soft outside of a few inches covering a heart of hardwood, usually black. Several trees have sand-coloured and reddish woods—very similar to the so-called California redwood.

The most valuable of all Borneo timber is billian, or ironwood. This is an extremely hard timber, sand-coloured when newly cut, but it darkens with age. It is so heavy that it sinks in water, and for that reason cannot be rafted down the rivers. About 2 inches of the outside of the tree is soft and worthless, but the inside can be used for

almost any practical purpose where a strong, solid, and durable wood is required. It is particularly in request for building purposes in the tropics because it is ant-proof. For all purposes for which heavy hardwood is preferred, such as cabinet or furniture making, dancing-floors, inside finishing of railway carriages, timber for vehicles, etc., billian is admirably adapted. The only objection is its great weight; but that is counterbalanced by its great strength. It takes a fine polish, and is not affected by the elements. It is comparatively plentiful all over Borneo, though the supply immediately around Sandakan is getting short, as many shiploads go to China every year.

Russak and Sirayah.

Another valuable hardwood is russak or selangan batu. This is a dark sand colour and has many of the properties of billian wood, though it is not so heavy nor does it take so high a polish. Billian is more like reddish-brown ebony, if the description may be allowed. Russak is used for general building purposes, but is preferred for posts and piles for wharves, beams for houses, and all kinds of heavy framework. It is an admirable wood for interior finish in halls and churches for wainscoating and panel woodwork. The supply is practically unlimited.

The next common timber is sirayah, or redwood, a comparatively soft wood, very similar to California redwood. Sirayah putch i, a white wood closely resembling American yellow pine. Sirayah proper is so easily worked that it is in very common use. For all building purposes which do not require hardwood sirayah is in great demand: it has even been used for making railway coaches, as several shiploads went to Australia for that purpose. It takes a pretty polish, and is not readily attacked by white ants, though borers seem to thrive on it.

Urat Mata and Greeting.

A very valuable timber is known by the local name of urat mata. It is a dark-red colour, grained, not dissimilar to American mahogany, and much desired for shipbuilding, masts, and planks. It is very durable, and impervious to ants and other insects. The Malays prefer this wood for the bottoms of their boats. It is not so plentiful as billian and sirayah, but can be had in shiploads on a month's notice.

Greeting is a wood closely resembling Indian ebony, though the black inside is sometimes relieved by streaks of brown or red. It grows near the shore and on the edge of swamps, and is very durable both in and out of water. It may be used for all fancy and decorative purposes, including furniture, though it is almost as heavy as billian. Greeting is a good imitation of English black oak, and might even take the place of walnut. In a new country it is the first wood to disappear.

Rungas and other Valuable Timber.

Another wood similar in texture and grain to greeting is rungas, a dark-red wood with a black stain. The heart is a beautiful dark red. Two or three inches of the outside are soft and worthless, but the inside has all the qualities of the most desirable hardwood. It is durable, impregnable to insects or the elements, and takes a high polish. It is not so heavy as billian or urat mata, as it floats. This wood is not found in forests, but grows as isolated trees. It is found all over Borneo.

Other timbers valuable to the export trade are camphor wood, mirabow, and chindana. These woods all have a more or less agreeable scent, and are fine-grained and durable. They are in great demand in Hong-Kong for the inside finish of wardrobes, chests, bureaus, and all wooden furniture intended to contain clothing. These woods are also adapted for fine building purposes and furniture. In the tropics they are used for stairways, doors, window-frames, and finishing work generally.

Imitation Ebony.

The woods described are those in demand for export purposes. There are many other kinds which partake more of the nature of the balsam, white pine, and other softer woods of America. These have not been referred to, with the exception of sirayah, for the reason that they would not be of interest to anyone outside the country. The only other tree that might be mentioned is an imitation ebony. It is another of the woods that has a soft outside and a hard inside. The inside is black, and to all outward appearances is the same as ebony. It is exported to China, where it is used for veneering and inlaying purposes. Sometimes it is made into furniture.

Lumbering Cost.

The cost of procuring timber is not great. The system in vogue near Sandakan is to fell the timber, using Chinese coolies, and raft it down rivers to the bay, where it is loaded into lighters, which go alongside the big steamers and discharge.

It is claimed that the supply of nearly all kinds of timber in British North Borneo will last hundreds of years. Mr. Matthews is not expected to make a report of his investigation for several months; but, as the entire surface of the country is covered with forests, he will no doubt declare the supply practically inexhaustible. At present two companies only are engaged in the export timber trade. The entire supply goes to Hong-Kong.

KAURI GUM IN NEW ZEALAND.

In 1914 a Commission was appointed by the Governor of New Zealand to inspect and classify the kauri gum reserves in the Land District of Auckland, and in particular to ascertain (*a*) which reserves contain or yield sufficient gum to justify their retention as reserves, and (*b*) which reserves are sufficiently exhausted of gum to justify the removal of the reservation

and the opening of the land for settlement purposes.

The report of this Commission has now been issued, and is entitled "Kauri Gum Reserves in the Auckland Land District."

The work of the Commission involved the inspection of 160 reserves, representing a total area of 228,000 acres, scattered over a wide expanse of country extending from Te Kao, near the North Cape, as far south as Katikati, in the Bay of Plenty.

Brief descriptions are given of the kauri gum lands of the northern peninsula, together with a short account of the origin of the reserves.

In the early days of settlement in New Zealand the industry was carried on chiefly by the pioneer settlers and small farmers, and by a steadily-increasing stream of immigrants from South-Eastern Europe. The latter engaged in gum digging as their regular occupation over the vast areas of unoccupied Crown and other lands, which were then of little value. This influx resulted in an over-production of kauri gum, and a slump in the industry followed, which was very keenly felt by the small settlers and original gum diggers. In 1898, in order to protect the interests of the pioneer gum diggers, and to some extent to check this influx, the Kauri Gum Industry Act was passed. As a result, gum reserves were established, and all gum diggers were required to pay an annual licence fee amounting to 5s. in the case of British subjects, and £1 (later increased to £2) in the case of aliens. From the passing of this Act up to the present time a total area of 276,210 acres has been set apart as reserves, of which certain areas, amounting in all to 48,849 acres, have been withdrawn from reservation for various reasons. Most of the land so withdrawn has been selected for settlement.

The total area of the gum-bearing lands (which are all in the Auckland Provincial District) was estimated in 1898 at 814,000 acres. Of this area 435,000 acres were then Crown lands, the balance being represented by privately-owned lands and native lands which had not been adjudicated on by the Native Land Courts. Prior to 1898 there were no restrictions of any kind on the gum diggers. Since that date a certain amount of protective legislation has been introduced, but up to the present time no attempt has been made to prevent gum land from being rendered useless for farming purposes. As a result, the gum diggers have wandered at will over the Crown lands, digging holes varying in depth from 3 ft. to 15 ft., which they are not under any obligation to fill in; in some cases there are as many as two hundred of such holes to the acre. In addition, the vegetation growing on the lands has been fired year by year by the diggers, and at all seasons. The effect of these successive fires has been to destroy the humus and surface soils, together with gum deposits of very considerable value, while in the case of many peat flats and swamps the fires have gutted them almost to the water level. In contrast to this state of affairs instances are given of private owners who have drained their land and let the gum-digging rights at a substantial royalty on condition that any holes made should be filled in, and all roots, stumps, etc., met with should be thrown up on the surface of the ground, leaving the land in a suitable condition for farming purposes. The Commissioners consider that the proper development of the Crown gum lands, under judicious management along the lines above described, would solve the "unemployed" difficulty for many years to come. The work should prove self-supporting, and the land would be left in a condition suitable for farming. Experiments have shown that gum lands, after breaking in, are suitable for general farming, and certain areas are considered to be well adapted for fruit-growing and for afforestation purposes. It is recommended that the lands should be developed by the State before being offered for selection, as the settlement of the gum lands by men possessing little or no capital would probably prove a lengthy process.

The Commissioners recommend that the reservation be removed from various kauri gum reserves of a total area of 71,164 acres. A schedule of the individual reserves is given. They are also of opinion that immediate steps should be taken to check the advance of a sand drift which threatens to overwhelm an area of 300,000 acres on the peninsula north of Ahipara. Of this area 100,000 acres are Crown lands, including gum reserves. A brief account is also given of the importance and value of the kauri gum industry. The Commissioners conclude the report by recommending that a small Department should be created to take charge of the Crown gum lands and the kauri gum industry generally, such a Department to be made self-supporting by imposing an export duty of £1 per ton on kauri gum.

According to the *Chemist and Druggist*, a Bill amending the law in regard to the kauri gum industry in New Zealand was passed in October, 1914. The Prime Minister of New Zealand, in moving the second reading, stated that soon after the outbreak of war gum became unsaleable, and several thousands of men were threatened with unemployment. To obviate this Parliament was asked by the Government for £50,000 to make advances on gum to the extent of not more than 50 per cent. of its value. The kauri would be taken possession of by Government representatives and stored till the market improved. In normal times a large proportion of the gum was exported to Germany for use in the manufacture of varnishes and linoleum. Since the outbreak of war the

demand from the United Kingdom has fallen off, but that of the United States was still being maintained. The Premier also stated that the Government intended to work the gum-bearing lands along the lines suggested in the report of the Commission referred to above, and it was thought that the gum thus obtained would realise more than sufficient to pay the men the current rate of wages.

THE MOLASSES PROBLEM IN CUBA.

An important paper by Mr. Noël Deerr on the Cuban sugar industry is reproduced in the latest issue of the *West Indian Bulletin* (the official organ of the Department of Agriculture of the West Indies), and includes the following observations on the molasses problem in that country. Mr. Deerr argues that the price obtained normally for molasses is not reasonably high enough if one works out the value of molasses on the basis of its industrial potentialities, which include the manufacture of alcohol, potash (both very important just now), and nitrogen. To these might be added the utilisation of molasses directly on a large scale in pig-raising, and its employment in the manufacture of acetone, used in the preparation of explosives. Mr. Deerr says:—

"Connected intimately with the well-being of the cane-sugar industry in Cuba is the molasses problem. At the present moment the molasses production in the 178 factories in Cuba is sold at rates varying from 2½ to 4 cents per gallon, and this may, on an average, be estimated to give the sellers a profit of one cent per gallon. I do not think this profit is reasonable, and I particularly wish to place before you the facts as to the molasses annually produced in Cuba.

"For the crop of 1913–14, the sugar production of Cuba was very nearly 2,600,000 tons: at a low estimate this must have produced 40 gallons of molasses per ton of sugar, or, in all, 100,000,000 gallons of molasses. With the most modern processes of fermenting and distillation, these 100,000,000 gallons of molasses could have produced 40,000,000 gallons of commercial alcohol; in actual practice at the present time, as a source of power, alcohol is worth, bulk for bulk, 60 per cent. of gasoline; these 40,000,000 gallons of alcohol would thus be equivalent to 24,000,000 gallons of gasoline, worth 36 cents per gallon, or a total of $8,640,000. This would give to alcohol a value of 23 cents per gallon, and enable it to compete with gasoline.

"In addition to the sugar in the molasses, a very great proportion of the potash removed from soil by the crop of cane is to be found in the molasses. I have not available any analysis of Cuban molasses showing the percentage of potash, but in all probability this will not be below 3 per cent. The 100,000,000 gallons produced for the crop of 1913–14 in Cuba will weigh in all 600,000 tons, so that this molasses will contain 18,000 tons of potash. The present price of sulphate of potash in Cuba is $55 per ton, which would give to the potash a value of $110 per ton. The 18,000 tons of potash contained in the molasses have, then, a value at the current price of $1,980,000.

"In addition to the potash, molasses contains a small but very appreciable quantity of nitrogen, which I will, in the absence of detailed analysis of Cuban molasses, take as being 0·5 per cent.; then there is contained in the molasses, 3,000 tons of nitrogen, having a market value of $1,200,000 when valued as a commercial fertiliser.

"In addition there is a small quantity of phosphoric acid in molasses, which will not be taken into account.

"The following tabulated statement gives the gross value of the three principal products of the molasses output, based on a production of 2,500,000 tons of sugar:—

Alcohol, 40,000,000 gallons, worth 20 cents a gallon	$8,000,000
Potash, 18,000 tons, worth $110 a ton	1,980,000
Nitrogen, 3,000 tons, worth $400 a ton	1,200,000
	$11,180,000

"It is one thing to make a calculation showing the possible value of the products to be obtained from the molasses produced annually in Cuba, but before these can easily be realised it is necessary to demonstrate the possibility of a market for them. I believe that a very extended use for the alcohol capable of being produced locally can be found within the limits of the sugar plantation in the following cases:—

"(a) Alcohol-burning locomotives;

"(b) Alcohol-burning tractors, to be used in propelling ploughs, cultivators, and other agricultural implements.

"The 18,000 tons of potash contained in the molasses produced annually in Cuba are several times more than the quantity imported annually into Cuba for use as a fertiliser, which amounts at present to about 3,000 tons. I am informed that great difficulty would arise in the marketing of this product, since the world's supply of potash is controlled by a German syndicate prepared to crush any competition; this monopoly of potash is keenly resented in the United States, where any source of supply would be eagerly welcomed, and where we should have to look for a market.

"I would, in addition, point out to you that the recovery of alcohol, potash, and nitrogen from the molasses presents no technical difficulties, as many plants on the Continent of Europe already work up beet molasses. The process is simple, and the plant not expensive; I estimate that ten centralised distilleries,

established at different points in Cuba, could be erected for a capital cost of, say, $1,800,000, and that these would be capable of treating the whole molasses output of Cuba.

"The one outstanding trouble in Cuba is shortage of labour. The increase of the capacity of a limit of labour through the medium of mechanical appliances will always be of great benefit to a community such as exists in Cuba. A cheap source of power, at present almost wholly unutilised, is available, and I believe that it would be greatly to the advantage of the Republic."

COTTON MILLS IN CHINA.

The cotton-manufacturing industry in China did not enjoy the same degree of prosperity in 1914 as in the preceding year. During 1913 the mills ran on full time through the greater part of the year, there was a strong demand for yarn at good prices, and the results of the operation of the mills were highly satisfactory. Some of the foreign-managed mills made net profits of 30 or 40 per cent. of their capital. In the early part of 1914 the prosperity of the preceding year continued; but the stagnation in general trading circles and the curtailment of the country's exports of native produce, following the outbreak of the European war, seriously affected the local mills. The demand for cloth and yarn fell off considerably, and production was somewhat curtailed. At present, however, nearly all the mills are operating their spindles night and day; those that have weaving departments are running their looms in the daytime only.

Fairly Good Year for Mills—Growing Use of Chinese Yarn.

In spite of the adverse conditions in 1914 the mills had a fairly prosperous year, and those under foreign management, with one exception, declared dividends only slightly less than in 1913. According to a report by the United States Commercial Agent at Shanghai, the year 1914 was notable for the degree to which yarn made in Chinese mills displaced Japanese and Indian yarn. For the first time the deliveries of Chinese yarn in Shanghai exceeded those of foreign spinnings. The actual deliveries at Shanghai of Shanghai, Japanese and Indian yarn were as follows: Shanghai, 56,752,000 lb. in 1913 and 77,850,133 lb. in 1914; Japanese, 59,687,066 lb. in 1913 and 66,727,333 lb. in 1914; Indian, 78,902,666 lb. in 1913 and 68,839,600 lb. in 1914.

As Shanghai is the most important market in China for the sale of yarn by importers to dealers in all parts of the country, these figures indicate the extent to which the local mills have been able to compete with yarns purchased abroad. India furnishes counts 10, 12, 16 and 20; Japan, 16 and 20; while the mills in China make mainly 10, 12, 14, and a small quantity of 16 and 20.

Production of Chinese Mills.

The total annual production of the mills in China is 200,000,000 to 250,000,000 lb. of yarn and 40,000,000 to 50,000,000 yards of cloth; during 1915, if the mills operate on full time, the yarn production will doubtless reach 300,000,000 lb., owing to the increase in the number of spindles during the past few months. The weaving industry is still in its infancy, but is gradually being developed. The principal kinds of cloth woven are 36 in., 48.48; 2.50, 2.85 and 3.00 yard grey sheeting, and 30 in., 68.44 or 68.48, 2.85 and 3.00 yard drills. One of the mills in Shanghai has recently begun to weave Canton flannels, and the goods have sold very well in the market.

Cotton Mill Statistics—Raw Cotton—Success of Cotton Mills.

There is no organisation among the Chinese cotton mills and there are no Government industrial statistics; but figures compiled by a Shanghai firm and believed to be approximately correct show that there are thirty-two cotton mills in China with 1,009,856 spindles and 4,610 looms. During 1914 about 100,000 were added to existing mills and several new plants were launched, but are not yet in operation. Although the total number of spindles is not large, it must be remembered that practically all the mills run day and night on a 23-hour schedule.

The bulk of the raw cotton consumed in the mills in the country is Chinese, which is only three-fourths to seven-eighths of an inch in staple and more harsh than American; it is fairly suitable, however, for spinning low counts. For making Nos. 16 and 20, Indian and American cotton is mixed with the locally grown staple. The present price of the best quality of Chinese cotton in Shanghai is 3½*d*. to 4*d*. per lb.

A supply of raw material, an abundance of extremely cheap labour, with no restrictions as to the hours of work or the employment of children, and a large domestic market for yarn and cloth, are the chief factors in the success of the Chinese cotton industry. It has already passed the experimental stage, and all indications point to further development in the next few years.

PANAMA HAT INDUSTRY IN COLOMBIA.

Toquilla straw, from which Panama hats are made, is obtained from five or six species of the palm. The most important of these is known as *Carludovica palmata* and grows in the warm, moist regions of the Pacific coast in Colombia and Ecuador, and also in the forests of Peru

along the headwaters of the Amazon. This palm attains a height of 6 ft. to 10 ft. The leaves are fan-shaped. Toquilla straw is exported to the United States and other countries, where the hats are made by machinery.

It has been suggested to the Colombian Government that the exportation of iraca and toquilla seeds should be prohibited in order to prevent other countries from cultivating those plants. It is also urged that it would be wise to levy a heavy export duty on the exports of toquilla straw, and to enter into an agreement to that effect with Ecuador and Peru.

A Colombian consular officer is authority for the statements that Japan is importing straw to promote the manufacture of Panama hats in that country; that at present there are large palm plantations in Formosa; and that the hats known to the trade as Jipijapas are now made in Japan, and are competing on equal terms with the products of Peru, Ecuador and Colombia.

According to a report recently sent to his Government by the United States Consul at Cartagena, Panama hats are made in Colombia in the following manner. When the palm is about 5 ft. high the most tender leaves are cut and the veins taken out, submerged in boiling water several times, and placed in the sun to dry and whiten. Further, to whiten the straw lime-juice is added to the boiling water. Then the straw is moistened to make it flexible and split with the finger-nail into strips of the required width. A bunch of the straw is tied in the middle and placed in the centre of a wooden mould. The fibres are placed in equidistant pairs, and weaving is begun in the upper part of the cup and continues in circular form until the hat is finished. The addition of fibres while weaving the crown is carefully avoided, and the number of fibres is increased to make the brim and edge. The beauty and durability of the hat depend largely upon the degree of exactness with which the fibres are interwoven. Once completed, the hat is washed in clean cold water, a coat of gum is applied, and the hat is finally polished with dry sulphur.

To weave a fine hat requires three to six months with four to five hours' work daily. Two inferior hats of ordinary straw can be woven in one day. First-quality hats of toquilla are sold in the foreign retail markets at prices varying from £5 to £20 each.

The declared exports of Panama hats from Cartagena to the United States have been steadily increasing. During the past five years the exports were valued as follows: 1910, £38,000; 1911, £43,500; 1912, £45,000; 1913, £52,800; 1914, £52,600.

Practically all the exports from this port go to the United States. During 1914 the only other market was the United Kingdom, which took hats to the value of £1,380.

The grades and current wholesale prices per dozen of Colombian hats (exclusive of commissions, charges and transportation expenses from the interior) are as follows: Electos, £1 17*s.* 6*d.* to £2 5*s.* 10*d.*; selectos, £2 5*s.* 10*d.* to £2 14*s.*; superiores, £2 14*s.* to £3 2*s.*; extrasfinos, £3 2*s.* to £3 10*s.*; finos, £3 10*s.* to £4 1*s.*; extras, £4 1*s.* to £4 7*s.*

EDISWAN ELECTRIC LAMPS.*

Since the amalgamation of the Edison and Swan companies in the year 1883, great progress has been made in electric lamp manufacture. The principal constituent of a lamp is the filament, because on its strength, economy in current consumption, and amount of light given off depends success or failure.

The filament is to-day made principally from pure tungsten wire-drawn, and it has been proved that this form of filament is exceedingly strong, will save 75 per cent. in current consumption against carbon filament lamps, and gives unexcelled brilliancy. Tungsten was at one time only procurable abroad, but can now be prepared from a tungsten concentrate obtainable in Cornwall, which enables the Ediswan company to be absolutely independent of imported raw material. Briefly, the tungsten in a powdered state is compressed under great hydraulic pressure into thin rectangular bars, which are kept at a very high temperature in a hydrogen flame, so that all impurities are removed. Then after electrical treatment, which makes the bars more solid, the material is ready for beating or swaging, which is carried out under great heat, and the finished article is a long thin rod of tungsten, which is gradually "drawn" down to the familiar thread-like wire seen in lamps. After the delicate process of assembling glass foot, stem, leading in wires, and supporting spiders (or arms) is completed and one piece is formed, the filament is wound on the supporting spiders. In bulb lamps the upper supports for the filaments are of strong and rigid nickel wire; the lower ones are of molybdenum which is thinner and more elastic.

The next process is to fix the filament in the form of a "cage" into the bulb, into which it is hermetically sealed. The lamp is then exhausted of air by pumps producing the highest obtainable vacuum. The Ediswan company is exceedingly well supplied with means for glass-making, having three large houses in full working order and a fourth (10-pot house) just being completed. The original small house used many years ago has also been reopened. The ingredients and mixing of the glass are not disclosed to anyone, because it has been the work of highly skilled chemists to produce the present high quality glass for Ediswan bulb-making.

After the preparation of a "batch" it is put into a crucible in the furnace, the glass by this time being known as "molten metal." In making

* From a report of a visit of the Society of Engineers to the works of Messrs. Edison & Swan, Ponder's End.

a bulb, one of the operatives dips his rod (hollow metal tube) in the molten glass and a sufficient quantity is deposited on the end. After a little blowing and motion through the air the partly-blown glass is placed in a mould manipulated usually by a youth, then blown to the shape of a lamp in the mould. It is then knocked off the tube and sent to a sorting department, where all imperfect bulbs are rejected. The Ediswan glass-houses are kept continuously running by eight-hour shifts.

After the exhaustion of the lamps the next procedure is to measure the candle-power and wattage on a photometer, after which the lamp is sent to be capped, the last stage being the etching on the glass bulb of the trade mark, candle-power, etc.

UTILISATION OF WASTE SUBSTANCES IN ITALY.

At a recent meeting of the "Associazione Chimica industriale Italiana," held at Turin, reference was made to the utilisation of certain waste substances and by-products for the manufacture of potash salts. The consumption of these salts in Italy has increased considerably of late years, and up to the present time that country has been dependent on Germany for the supply of this fertiliser.

It was pointed out that three other sources for the supply of these salts are at hand at home, viz.:—

(1) In the mother waters of the evaporating basins at the numerous saltworks (*saline*) along the sea-coast of Italy.

(2) From the *molasses*, or residue of the sugar works, where there is always an abundant supply.

(3) From the black watery liquid which remains in the "marc," or cake, that remains after the oil has been extracted from the olive berries. This liquid is said to contain 3 per cent. of crude potash salts, from which 50 to 60 per cent. of carbonate and from 15 to 20 per cent. of chloride of potassium can be extracted.

The soap-making industry might profit very considerably by the general adoption of the Garelli-Depaoli process, by which common salt can be substituted for soda in the saponification of fats. This might be rendered possible were the present fiscal restrictions removed—salt being a Government monopoly in the Continental part of the kingdom. In the island of Sicily, where such restrictions do not obtain, the process is being worked with satisfactory results. Rock salt is found in abundance in the province of Girgenti.

There should be in Italy, as is the case in France at Cannes and Grasse, a large field for the distillation of essential oils from flowers. This industry, with the exception of the essence of bergamot, a speciality of Reggio Calabria, and the essence of lemon, peppermint and lavender, can scarcely be said to exist in Italy, notwithstanding the large quantities of flowers cultivated on the Italian Riviera. Oil of lavender, which is used in the manufacture of a superior grade of varnish, as well as for perfumery, is made on a small scale in the valley of Susa and in the neighbourhood of the Col di Tonda. There is a great future for Italian chemical industry in the manufacture of dyestuffs, and particularly aniline colours, for which Italy has been, up to now, dependent upon Germany.

GENERAL NOTES.

Indian Wheat Forecast.—The final wheat forecast for 1914-15, covering all the important wheat-growing areas of India, shows the total estimated yield to be a record one, even higher than the heavy crops of 1903-4, 1910-11, and 1912-13. The total area now reported is 32,330,000 acres, being 13 per cent. above the final estimate of the previous year. The yield is estimated at 10,269,000 tons (or 47,923,000 quarters of 480 lbs.), showing a substantial increase of nearly 23 per cent. over the figures of last year. The outturn per acre works out at 714 lbs., or approximately 12 bushels, which is only a fair rate of productivity compared with the figures from 1903 outwards. In the United Provinces it is estimated that 7,303,000 acres are under the crop, an increase of 14 per cent., while a yield of 3,041,000 tons, or 7 per cent. larger than last year's, is anticipated. The corresponding figures in the Punjab for this year are 11,195,000 acres and 3,925,000 tons, being increases of 17 and 23 per cent. respectively. The latest available information regarding the wheat crops of the world shows the following estimates of area: United States, 41,246,000 acres, increase of 11 per cent.; Canada, 1,062,000 acres, increase of 9 per cent.; Italy, 12,350,000 acres, increase of nearly 5 per cent.; Argentina, 15,447,000 acres and 5,176,000 tons yield, increase of 70 per cent.; Australia, 790,000 tons, decrease of 71 per cent.; and Chile, 600,000 tons, increase of 90 per cent.

Glass Factories in the United Provinces.—The United Provinces Government has asked the Government of India to move the Secretary of State to appoint two Belgian or English glass experts with a view to the introduction of improved and up-to-date processes in the glass factories of these provinces. In making this request the United Provinces Government is acting on the recommendation of the committee they appointed at the outbreak of the war to investigate the possibilities of assisting local industries to capture a share of German and Austrian trade. The inquiries of the committee show that one of the most promising openings is to be found in the glass industry, which is carried on in several parts of the United Provinces. "This trade," says the United Provinces Government's letter to the Government of India, "though still in its infancy, offers great

possibilities, for not only are the manufacturers, who have already indulged in various costly experiments, possessed of capital and quite prepared to sink it in improvements, but they are also fully alive to the unique opportunity offered by the present crisis for invading the extensive markets in which German and Austrian firms have hitherto enjoyed the monopoly." The two experts, when appointed, are "to teach the business of glass-making and its methods fully and without reserve to the employés of any factory to which the Local Government may post them."—*The Pioneer Mail.*

The Professional Classes War Relief Council.—A permanent exhibition of pictures and decorative arts, under the auspices of the Professional Classes War Relief Council, is being held at 13, Prince's-gate, S.W. (by kind permission of Mr. J. Pierpont Morgan). The special features of the exhibition are portraits, miniatures, wedding presents, and rolls of honour. The exhibition is open free daily from 10–1 and 3 5 (Saturdays 10–1).

Papyrus for Paper-pulp.—The papyrus grows in great quantities on the Upper Nile, in some places covering an area of a kilometre or more on either side of the river. In 1908 experiments were conducted at the Wellcome Tropical Research Laboratories, Khartoum, with a view to ascertaining whether this could be converted into satisfactory pulp for paper-making. As far as could be ascertained from trials on a small scale, the results appeared promising. Further steps have now been taken, and an account of them is published at Khartoum in a short article by Dr. William Beam, research chemist at the laboratory. Experiments on a larger scale were carried out for the "Sudd Fuel (Suddite)" Company by Messrs. Tullis, Russell and Co., and by Messrs. Thomas and Green, under the auspices of Messrs. Cross and Bevan. These indicated a valuation about equal to esparto, and several very promising features were noted. The colour was approximately up to the standard of ordinary bleached supply, and the pulp could be used as an "entire furnish," *i.e.*, without the admixture of wood or other long fibre The raw material in the shape of air-dried stalks was estimated at about £3 per ton, delivered in England.

The Lighting of Rifle Ranges.—At the annual meeting of the Illuminating Engineering Society a discussion on "The Lighting of Rifle Ranges" was opened by Mr. A. P. Trotter, who ave an interesting account of his experiences in shooting on miniature rifle ranges. Many members of the society, and others associated with volunteer corps and rifle clubs, joined in the discussion. The art of aiming involves problems of vision, and is therefore materially affected by the lighting conditions. Men of advancing years, having defects in eyesight, are subject to certain difficulties in learning to shoot, and are specially sensitive to the defects in lighting. The ordinary method of lighting miniature ranges seems open to criticism from this standpoint, and Mr. Potter described a special system which he had successfully tried in connection with Mr. Brazil. The general impression was that the extreme contrast between the brightness of the target and the dark surroundings commonly met with in rifle ranges was undesirable, and that an attempt should be made to reproduce more closely the actual conditions prevailing in nature. Mr. A. Blok gave an account of a series of tests on various ranges in London. Experiments had been made to ascertain the desirable brightness of illumination for targets. It was agreed by several speakers that excessive illumination gave rise to an impression of "glare," and it even suggested that 15–20-ft. candles would be ample for ordinary purposes. The whole discussion was summarised in the June issue of the *Illuminating Engineer*. It is proposed to form a joint committee in order to study these problems more closely. In view of the large number of rifle ranges springing up over the country, this should be a most useful piece of work.

National Belgian Soldiers Comforts Fund.—An urgent appeal has just been issued on behalf of the above fund, which has for its object the employment of Belgian women refugees in ministering to the needs of their own soldiers. At present there are 130 work-circles scattered throughout Great Britain, and supplied gratis from the headquarters of the fund with materials for the work. The garments made are transmitted to the troops under the auspices of the Belgian Legation and the Admiralty. Letters received from the soldiers testify to the touching gratitude with which these sorely-needed comforts are received, while on the other hand the Belgian women are delighted to have this opportunity of helping their country, and are eager to have further supplies of materials; but, unless contributions are immediately forthcoming, it will be impossible to continue the good work. The committee, which has achieved remarkable results on a very small expenditure, has its headquarters in Cambridge, and contributions should be sent to the Honorary Secretaries of the Fund, 6, Selwyn Gardens, Cambridge.

A New Lubricant from Molasses.—The German press announces the grant of a patent to a Mr. H. Steffens for making a lubricating substance out of beet-sugar molasses. The United States Commercial Attaché at La Hague, in a report on the subject to his Government, states that it is not yet known whether the new lubricant is at all practicable, as it is still in the experimental stage. He adds that the normal production of molasses in Germany is about 450,000 tons a year, but that it would be an easy matter largely to increase this output.

Journal of the Royal Society of Arts.

No. 3,269. VOL. LXIII.

FRIDAY, JULY 16, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

This competition was instituted in 1878 by the Council of the Royal Society of Arts, as trustees of the sum of £400, presented to them by the Committee of the Owen Jones Memorial Fund, being the balance of subscriptions to that fund, upon condition of their spending the interest thereof in prizes to "Students of the Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings. Damask, Chintzes, etc., regulated by the principles laid down by Owen Jones." The prizes are awarded annually on the Report of the Examiners in the National Competition of the Board of Education.

Six prizes were offered for competition in the present year, each prize consisting of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's Bronze Medal.

The following is a list of the successful candidates:—

Buswell, John B., School of Art, Nottingham, for a Design for a Machine-made Lace Curtain.

Howells, Frederick W., Broad Weir School of Art, Bristol, for Designs for Tile Fireplaces.

Wheeldon, William H., School of Art, Morecambe, for Designs for Printed Cottons.

Rowe, John H., School of Art, Dudley, for a Design for a Stencilled Hanging.

Brocklehurst, Harry, School of Art, Macclesfield, for Designs for Furniture Silks.

Grainger, Harold, School of Art, Macclesfield, for a Design for a Printed Linoleum.

The examiners who judged the works submitted for this competition report that "Generally the standard of merit is equal to that of last year, although there is a slight improvement in the treatment of colour.

"Whilst a considerable number of the designs show too close a resemblance to well-known historic examples, which, in some instances, have not been intelligently studied, there are some which are original in treatment and at the same time adhere to the principles laid down by Owen Jones.

"The most successful among the competing works include examples of lace, woven silks, tiles, linoleum, embroidery, and carpets."

SPECIAL WAR LECTURES.

On Wednesday afternoon, July 14th, Professor Vivian B. Lewes, F.I.C., F.C.S., delivered the second lecture of his course on "Modern Munitions of War." The subject of the lecture was "Mines, Shells, and High Explosives."

The third lecture, which will deal with "Poison Gases and Incendiary Bombs," will be delivered on Wednesday, July 21st, at 4.30 p.m.

The lectures will be printed in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

FOTHERGILL LECTURES.

MOTOR FUELS.

By Professor Vivian B. Lewes, F.I.C., F.C.S.

Lecture II.—Delivered February 22nd, 1915.

Petrol Substitutes.

In the last lecture petrol was taken as the standard motor fuel, and the characteristics that fit it for that position were dealt with fully in order that we might have something with which to compare the various substitutes that have been proposed from time to time.

Prior to the demand created for it by the coming of the motor-car, petrol was almost a

waste product; it had to be distilled off from the crude oil before the kerosene, which in those days was the important product, could be obtained of a flash-point to satisfy legislative requirements, and the uses to which it was put were chiefly as a grease solvent for wool and dry cleaning, a little also being used in flare lamps of the Holliday type and for sponge lamps. When the demand for it as fuel in the internal-combustion motor first arose the supply was more than sufficient to meet it, and prices rose but slowly, the bulk of the petrol imported into England coming from America.

Before the price had been seriously inflated the Dutch East Indies came into competition with the American supply, and this tended to keep down the cost, but the use of petrol in America was growing faster than it was here, the quantities used became enormous, and as it was necessary to fill home requirements the amount available for export to England became smaller. The Dutch East Indies then became the chief source of supply, so that in 1912 more than half the motor fuel used in England came from there. The falling-off of the American competition and the freight difficulties already alluded to led to rapid rise in price, but in 1914 the American exports of petrol to England suddenly rose again to 40,000,000 gallons, this being due to three causes—first, the closing of the German market; secondly, the increased shipping facilities; and, lastly, the production of enormous quantities of spirit formed by cracking residues by the Burton process, this, however, being used mostly in America, and so setting free large quantities of ordinary petrol for export.

When the price of petrol threatened serious harm to the motor industry, feverish attempts were made to find substitutes at a lower price, and naturally the body which suggested itself was benzol, the first member of the aromatic hydrocarbon series, which is produced in the tar formed during the destructive distillation of hydrocarbons at a high temperature.

The history of benzol is an eventful one. Discovered by Faraday in the liquid condensed on pressure from oil gas, it had little or no use until the discovery of the aniline dyes by Perkin, who made aniline by nitrating benzol and reducing the nitrate by nascent hydrogen. This at once created a demand for benzol, which rapidly rose in price from that of an almost worthless by-product to the neighbourhood of 15s. a gallon, and led to not only the perfection of the methods of distillation for extracting it from the coal-tar, which up to then had been its only source, but also to many experiments being made to obtain it by the cracking of oil residues and the scrubbing of rich gases.

A little later the Germans introduced recovery plant in their Westphalian coke ovens, in which benzol could be recovered from the gases before they were utilised as fuel for heating the coal charges, and this at once led to such an increase in the supply that the price began to fall almost as rapidly as it had risen. After a lapse of many years English prejudice against recovery oven coke began to be overcome and recovery plant applied to English coking, further largely increasing the yield of benzol. This caused a still further reduction in price, and ten years ago benzol could have been obtained in very large quantities at 6*d*. per gallon. It was under these conditions that it appeared to be not only an ideal motor fuel but, being a native product, one not liable to being interfered with by external complications. Unfortunately, however, the supply, which had been more than ample for all the demands made upon it for artificial colour production and the other uses to which it was put, proved utterly inadequate when it came to entering into competition with petrol as a motor fuel. An immediate rise in the price occurred, and, as must always be the case, its price became only just sufficiently low to give it an advantage in competition, whilst the anticipations formed by certain enthusiastic supporters of benzol and the wild statements made as to the amount produced led to absolutely fallacious expectations as to the position it would take in the market.

The truth about benzol is that if we take the total yield per ton of coal carbonised in the manufacture of coal gas and in coke ovens fitted with recovery plant, the average yield of crude benzol per ton would not exceed 2½ gallons, and in all probability would be nearer 2¼, and before this could be made available for motor-car work it has to be purified and redistilled, not more than 72 per cent. of the original being fitted for use for this purpose. This means a reduction in the yield of motor fuel per ton of coal to 1·8 gallons.

During the year 1912 ten million gallons of crude benzol were produced in this country, of which four millions were exported for the foreign colour trade. Great activity in fitting recovery plant in place of beehive coke ovens so as to recover as much of the benzol as possible then took place, and in 1913 the yield of benzol rose to between fifteen and sixteen million gallons, about five millions of which were

exported. Last year the increase in the coke-oven recovery plant and its extensive working for the purpose of getting the benzol was unfortunately checked by a slump in pig iron, and inasmuch as the demand for metallurgical coke is dependent almost entirely upon the iron and steel production, this led to overstocking in coke and a slackening down of the coke ovens, with the result that the production of benzol will have fallen slightly, but the stoppage of exports of benzol to Germany during the last five months of the year will have probably brought the amount of benzol available for use in this country up to about the same level as in 1913.

Although so much has been done of late years in checking the wilful waste due to carbonisation of coal in beehive ovens and simply burning-off all the valuable by-products so polluting the air for miles around, not very much more than half the total coking of coal is done in recovery plant, and if the whole of the beehive coking ovens were abolished and all metallurgical coke made in recovery ovens, and all the tar made in the gasworks was distilled and the benzol recovered, the total possible output for this country would be thirty-six million gallons, or about one-third of the volume of the motor fuel imported into the country during last year.

It is not likely, however, that we shall ever see the complete abolition of the beehive coke oven with its wastefulness and its pollution of the atmosphere, as there are some classes of coal which swell so much on carbonisation that they do not lend themselves to coking in recovery plant.

At the present moment the overstocking of the metallurgical coke market is leading to several collieries which produce a rich bituminous coal seriously considering the question of adopting a lower temperature of carbonisation than is used either in gasmaking or coke-oven practice, in both of which the temperature is so high that the coke has the last trace of volatile matter driven out of it, and so is difficult to ignite, and requires a strong draught to keep up an active combustion. It has been proved that there is an enormous market for a coke which contains about 6 per cent. of volatile matter, which should be easy of ignition and in the domestic grate burn with a bright clear fire. The market for a gas of good heating value for power purposes is also daily becoming greater for electricity works and commercial purposes, and the demand for aromatic hydrocarbons is becoming insistent, owing to certain of them being required for the preparation of explosives used in the war, whilst others will be needed in large quantities if the much-talked-of attempt to capture the German coal-tar dye industry is to be made, and with carbonisation at 900° C., recovery of crude benzol from the tar, and also by scrubbing the gas with a heavy oil, it would be possible to obtain between 4 and 5 gallons of crude aromatic hydrocarbons per ton.

In speaking of the carbonisation of coal as a source of motor fuel it must be borne in mind that with carbonisation of coal at 450 C., as carried out in the processes described by Dr. Perkin in the course of Cantor Lectures which he has just concluded, aromatic hydrocarbons, benzol, etc., are extremely low, their place being taken by light oils of the paraffin series and naphthenes, so that these would not be a source of benzol, which, with the further members of the aromatic series, is produced in maximum quantities by the carbonisation of coal at about 900° C.

Benzol as sold as a motor fuel contains also toluol and xylol, these three being the first members of the aromatic series, and having the composition and boiling-points:—

	Formula	Boiling-point °C.	Specific gravity
Benzol . .	C_6H_6	80·5	·886
Toluol . .	$C_6H_5.CH_3$	110·0	·865
Xylol . .	$C_6H_4(CH_3)_2$	137–140	about ·87

The general method adopted for separating benzol to be used as a motor fuel from coal tar consists in distilling the tar and subjecting the light oils so obtained to further fractionation, the lower boiling fractions being separated. These fractions are purified by treatment with sulphuric acid, whereby some of the sulphur, certain unsaturated hydrocarbons, etc., are removed. This is followed by treatment with caustic soda, by which tar acids, such as carbolic acid, are eliminated from the spirit, and finally a thorough washing with water is given. The treated and washed spirit is rectified in stills provided with a reflux apparatus, which allows the more volatile portions of the vapours to pass forward for subsequent condensation; but the heavier vapours are condensed and returned to the still. In this way it is possible to collect any distillate of definite boiling-point and specific gravity.

The demand which has now arisen for toluol for the manufacture of trinitrotoluol, or T.N.T., at present largely employed as a bursting charge in the shells which on detonation give the volume of black smoke that

has earned for them the sobriquet of "Black Marias," will undoubtedly lead to further fractionations, and reduce still more the proportion of benzol available as motor fuel.

Pure benzol, generally spoken of as benzene, has the drawback that it crystallises at 6° C., but the other bodies present with it in the commercial 90 per cent. benzol used for motor fuel lower the temperature at which crystallisation takes place, whilst the addition of 10 per cent. of petrol will keep it liquid well below the freezing-point.

For use in an ordinary motor engine it is exchangeable with petrol—*i.e.*, no alterations of carburettor or engine are necessary—and it develops about 12 per cent. more power. Unless properly purified, the smell of the exhaust is objectionable, and if the crude benzol without any purification is used trouble is sometimes found from the formation of resinous bodies, which tend to cause sticking of the valves, etc.

The calorific value of benzol is, per pound, 17,750 B.Th.U. gross and 17,100 B.Th.U. net, which is considerably below that of petrol, but its specific gravity is 0·886, that is, there are 8·8 lbs. to the gallon instead of 7·2 with petrol, with the result that the heat value per gallon is 156,700 B.Th.U. gross and 150,000 B.Th.U. net, which explains the 12 per cent. higher power obtained in use.

We have seen that benzene is a definite compound, and although it contains some toluol and xylol, a far larger proportion fractionates over a narrow range of temperature than we find with an avowed mixture like petrol. Pure benzene distils at 80° C., and the bulk of a commercial benzol distils between 80° C. and 100° C.

Another definite compound usable as a motor fuel, and one which will become of more and more importance as the world's supply of oil becomes depleted by the enormous demands to which it is subjected, is alcohol. The world's stored fuels—coal and oil—represent Nature's method of fixing the sun's energy in days long past by the growth of vegetation and its gradual conversion over long ages into our great solid and liquid combustibles. It was only during a passing phase of the world's history—a few thousand years probably—whilst our atmosphere was being fitted for the coming of the higher forms of animal life, that such accumulations of vegetable matter were possible as gave us our coal-fields and our oil deposits. To-day oxidation and decay would render it impossible, and when a century hence the world finds itself bankrupt in the fuels that have served it for centuries, and searches for others to take their place, it will be realised that the rapid growth in sunny climes of roots and grain that can be fermented into alcohol will be the only method of obtaining a fuel that will be sufficiently rapid to render it available.

Ethyl alcohol, C_2H_6O, is obtained by alcoholic fermentation from almost any material containing cellulose—corn, rice, potatoes, sugar-cane, beet, wood refuse, and even sawdust can be made to yield it—and no country is without material from which it could be produced. It forms in many ways an excellent motor fuel; its limitations are known, and the possibility of using it is purely a question of Government sanction. The great curse of alcohol is that it is an intoxicant, and that Government finds in taxing it and hedging it round with legislative restrictions one of their most fruitful sources of revenue. When it must be used as a fuel it can be made at 6*d.* per gallon, but its manufacture and use are so hampered by grandmotherly precautions and restrictions that the denatured or methylated spirit that is allowed to be sold "duty free" costs 2*s.* 4*d.* to 2*s.* 8*d.* per gallon, and under these circumstances petrol would have to rise to about 3*s.* 6*d.* a gallon before alcohol could compete successfully with it.

The denaturation or methylation of alcohol consists in mixing with it something that cannot be again separated easily, and which will render the mixture so nauseating that the most hardened drunkard cannot drink it in theory. As the law at present stands, only what is termed "mineralised methylated spirit" may be used as a motor spirit; it consists of alcohol (96 per cent. strong) mixed with one-ninth of its volume of wood naphtha and not less than three-eighths of a per cent. by volume of petroleum, which renders it turbid if mixed with water.

The wood naphtha or wood alcohol, CH_4O, used for denaturation is obtained from the pyroligneous tar yielded by the destructive distillation of wood, and its use for denaturing alcohol for motor use is responsible for one of the chief objections urged against the use of alcohol for this purpose, and that was that it caused corrosion of valves and other working parts. This, however, has proved not to be the case when other denaturants have been used; but there is a strong probability that if an engine is running light, and the temperature is low, a partial oxidation might lead to the

formation of an aldehyde, which might be converted into acetic acid.

The fact that the molecule of alcohol contains oxygen affects its calorific value, and if we make a comparison between methylated spirit and a ·722 petrol we find that the B.Th.U.s contained by a pound of alcohol are not very much more than half those of the petrol, so that if merely the thermal values of the two fuels were taken as representing their production of power, alcohol would not have a chance of competing with petrol.

I have already pointed out that the thermal value of a fuel is by no means a safe guide to the work that it will do, and alcohol is an excellent example of this. We have seen that the efficiency of a good form of petrol motor is 22, that is to say, only 22 per cent. of the heat value of the petrol is converted into work, and the loss which takes place is dependent upon a large number of different factors, such as the compression that can be used without fear of premature ignition, the amount of air needed to produce complete combustion, the cylinder temperature, and other points of similar character.

With petrol it is unusual to exceed a compression of more than 70 lb. for fear of pre-ignition, although it is sometimes carried to 90 lb., but with alcohol compressions as high as 200 lb. can be employed. In the next place, a pound of petrol requires 15 lb. of air for its complete combustion, whereas with alcohol only 8·75 lb. are needed, which means that the volume of inert nitrogen in the air which has to be heated to the same temperature as the other cylinder gases, and which acts as a diluent in slowing down combustion, is reduced by nearly one-half in the case of alcohol. Further, we have seen that the explosive range for petrol is extremely low, so that it is difficult to get the exact explosive mixture; but with alcohol the explosive range is more than doubled, whilst the explosion being much cooler than in the case of the petrol the cylinder temperature is not so high, and all these factors being to the advantage of alcohol we find that the efficiency of the engine using it can be increased to as high as 38, and that in trials with properly constructed engines the result given by alcohol, volume for volume, is very nearly equal to that of petrol.

As regards safety alcohol has an advantage over petrol, which is of the greatest possible importance: its flash-point, instead of being below the air temperature, is 58° F., so that instead of a summer's day causing volumes of vapour to be given off, as is the case with petrol, the evaporation is comparatively low; it does not creep in the same way that petrol does, and being much lighter than petrol vapour does not flow over the ground in the same way, whilst, being miscible with water, if it catches fire it can be extinguished readily and easily.

In France considerable attention has been paid to the utilisation of alcohol in motor-cars, and so important was the use of alcohol considered in Germany that the manufacture of alcohol by fermentation from potatoes was State-aided in order to keep labour on the land as far as possible; and alcohol for motor use became a commercial success, the benefits of which are being reaped at the present time when, the petrol supplies having been cut off, a petrol famine exists.

Our interest in petrol substitutes may be summed up as a desire to get a motor fuel cheaper than petrol; but if we desire to have an object-lesson in what we could do if petrol and petroleum products failed, we have only to turn to Germany's plight at the present moment, and there the subject is found to be one of the most serious national importance.

The whole conduct of the war depends on motor traction without it the movement of troops is hampered, the commissariat cannot be carried out properly, the supply of ammunition to the fighting line fails, and the Red Cross Service is rendered inefficient. At the same time, there is practically a petrol famine, and what there still is must be kept for the fighting line and the air service. Under these conditions the experience the Germans have had in using alcohol as a motor spirit is proving of great value in meeting the emergency. Every motor-car in Germany has been adapted to burn alcohol as well as petrol by fitting suitable carburettors that could be adapted to either fuel, and when used with alcohol could be warmed up to give the power of starting. We have seen that the thermal value of alcohol is only a little more than half that of petrol, but that higher compression is possible and makes the efficiency nearly the same; but the compression cannot be altered without serious alterations to the engine which would unfit it for use with petrol, whilst if the alcohol is used in the engine as arranged for petrol the power obtained would follow the ratio of their heating values. Nearly twice as much alcohol as petrol would have to be burnt to give the same power. In order to get away from these troubles

without any more alteration than that of the carburettor, a mixture of alcohol with benzol in which naphthalene has been dissolved to give it higher heating power is used. The favourite formula is :—

95 per cent. alcohol	80 litres.
Benzol with 200 grammes naphthalene dissolved in it	20 ,,
	100

And such a mixture when used without any extra compression gives five-sixths the power of petrol, whilst all the ingredients are made in the country.

It will be interesting to see in this connection how much motor fuel can be possibly made available in Germany.

In 1913 Germany produced 160,000 tons of benzol, of which 50,000 were exported; all exportation will now have ceased, and if we suppose the production to have been maintained and one-third recovered from the crude benzol as toluene, this would leave, allowing for wastage, 100,000 tons of benzene, or a total of 25,000,000 gallons, which, with the amounts used at both fronts and in the towns, would be at most six weeks' supply if used alone.

The production of alcohol in 1913 in Germany was 3,750,000 hectolitres, or 82,500,000 gallons; so that, supposing the whole of the benzol and alcohol made in the country were blended and the naphthalene, of which there is plenty, dissolved in it, the whole production of motor fuel possible would be a little less than the amount we imported last year, and would mean about a five months' supply at the present rate of consumption.

Leaving the simple compound class of motor fuels, we come to a large class of mixtures in which heavier portions of the crude oil are used.

In the distillation of crude oil the second cut consists of kerosene distilling between 150° C. and 300° C., and the volume of this grade is, of course, enormously greater in nearly all crude oils than that of the benzene or first cut. The demand for it also is still very large, the amount imported into England last year being 146,600,000 gallons, or some 26,000,000 gallons more than the petrol spirit.

Five or six years ago oil of this character could be got at 3*d.* to 4*d.* per gallon, whilst petrol was already over 1*s.*, and many attempts were made to form mixtures of it with benzol or petrol in sufficient quantity to allow of starting, and when the temperature of the cylinder and inlet pipe had got sufficiently high, and a good spray carburettor was used, such mixtures, if made in the right proportions, worked perfectly well as long as they were used for steady running without any great fluctuation in speed. Directly, however, one got into heavy traffic troubles began to show themselves, as the range over which the mixture of kerosene spray and air is explosive is even more narrow, indeed not more than one-half of that of petrol-air mixtures.

There must have been twenty or thirty patents taken for mixtures of this character, the nature of which was attempted to be disguised by the introduction of small quantities of other substances, which generally had no effect whatever, or by fantastic methods of treating and purifying the mixture before use. Given, however, the right proportions, the mixtures are of considerable commercial value for steady running on country roads, as, for instance, postal vans from London to the country centres, or the transport of goods over long distances. Even kerosene can be used by itself in a motor engine with an atomising carburettor as long as all the working parts are sufficiently hot when the kerosene is turned on and nothing happens to alter the ratio of oil to air. Several attempts have been made to utilise this fact by fitting double tanks and carburettors to the car, so that it can be started on petrol, and when thoroughly warmed up switched on to the kerosene, when the engine would run perfectly well until on slackening the supply was throttled and the engine would stop dead, owing to the proportion of oil vapour to air being thrown outside the narrow range over which it is explosive.

I have made many experiments on such mixtures, and for anything approaching satisfactory work the petrol has to constitute practically half the mixture before good results are obtained, and when, as at present, the price of kerosene is high very little saving can be secured.

Perhaps the most successful mixture of this class is 50 per cent. of kerosene distilling up to 250° C. with 40 per cent. of ordinary petrol having a specific gravity of about ·720, and 10 per cent. of benzol, the idea of such mixtures being that in a mixture of liquids of different boiling-points the escape of the vapour of the most volatile constituents carries with it considerable proportions of the ingredient of next higher boiling-point, this again helping the volatilisation of the still heavier fractions. Also if a carburettor is used that sprays the mixture as a fine mist into the cylinder, each particle of the mist will be a drop of microscopic size containing the constituents of the mixture,

and as the more volatile portions of each particle evaporate the particle itself is reduced rapidly in size until the last portion of the heaviest oil is so finely divided that its complete combustion is easily brought about. I think, therefore, that for commercial work mixtures of this character might often be employed satisfactorily. The rate of flame propagation in the mixture, however, is a side question that must not be overlooked, as if the rate of burning is made progressive, as it would be in such a case, it is obviously not fitted for very rapidly running engines, as a slow-burning mixture might not have completed its combustion by the time the inlet valve opened, and firing back would take place. It seems probable that the admixture of oxidising agents with heavier oils renders them more easy to burn in the cylinder of the internal-combustion motor, and in France it has been quite a usual practice to mix small quantities of picric acid and other nitrated hydrocarbons with the oil.

It has also been claimed that the admixture of small quantities of hydrogen peroxide to the oils exerts a remarkable influence on the way in which they burn, and enables heavier fractions to be used successfully. With all this class of motor fuels, starting from cold and flexibility in running have been the main troubles to contend with, and excellent results have been attained by the solution of hydrocarbon gases in them, which being readily disengaged have given the necessary ease of starting, and by having a wider range of explosion have endowed the fuel with flexibility. Of all the gases fitted to use in this way acetylene is undoubtedly the best, as it is of high calorific value, and so adds to the power of the fuel; it is also fairly soluble in benzol and alcohol, and so can be made of special value in giving to mixtures of them the desired starting power from cold, whilst having the greatest known explosive range it endows the mixture with flexibility in running. The right way to use it is to make a standard solution of the gas in benzol, one volume of which holds four volumes of acetylene in solution, and in making the motor fuel to add sufficient of this to give the necessary starting power.

I have known a motor spirit containing a mixture of kerosene and petrol touched up with a benzol solution of acetylene, retain its starting power for nine months, showing that when in true solution the tendency to "stale," so common with mixture fuels, does not take place to any large extent. When alcohol comes into use as a motor fuel this property may prove of considerable value, as one volume of alcohol dissolves six volumes of acetylene.

Even hydrogen, the least soluble of all gases, has been used for treating ordinary petrol, and it is claimed to give a 20 per cent. saving in consumption. In this case the escape of the small quantity of hydrogen from the petrol carries with it petrol vapour, and as the igniting point of hydrogen is less than one-half that of petrol vapour, it probably flashes through the gaseous mixture in the cylinder and causes a more rapid and complete combustion — it acts, in fact, like a priming of small grain gunpowder in a heavy charge of prism powder.

I alluded at the commencement of this lecture to the large quantity of residual oil that was being cracked in America for the production of motor fuel, and there is no doubt that whilst the world's production of crude oil remains at its present enormous figure such processes will be able to supply sufficient spirit to enable the petrol to keep up with the demand. The cracking of oil depends on the property which heavy hydrocarbon molecules possess, of dissociating under the influence of heat into simpler groupings of their atoms, so that when a heavy hydrocarbon is heated, instead of breaking up at once to carbon and hydrogen, the decomposition takes place in step with formation of bodies of more and more simple structure, until eventually entire decomposition takes place, whilst at the same time that this is going on the action of heat on the disintegrated groups of hydrocarbons nascent in the solution brings about polymerisation amongst them, and leads to the formation of heavier as well as lighter portions of an asphaltic character. If, however, the right conditions of temperature and pressure are employed, it is possible to convert a large percentage of the heavy residual oil into fractions light enough to be used as motor spirit.

This fact was first noticed in America in 1861, and four years later James Young, the father of the Scotch shale-oil industry, found that in the fractional distillation of the shale oil the volume of light spirits obtained could be largely increased by carrying out the process under pressure, an action which Sir Edward Thorpe and John Young in 1871 explained by means of an exhaustive research in the laboratories of Anderson's University, Glasgow, which was communicated to the Royal Society, and forms the most valuable contribution that we have to a knowledge of the actions taking place.

We have seen that the saturated hydrocarbons form a complete series, of which methane or

marsh gas is the first member, each succeeding member of the group being formed by the addition of one group of CH_2, so that in each member of the series the ratio of carbon to hydrogen may be expressed by the formula C_nH_{2n+2}

The four simplest members of the group are gaseous, and with the fifth commence the liquids, which extend from C_5H_{12} to $C_{14}H_{30}$; the hydrocarbons then become semi-solid, vaseline being a mixture of $C_{15}H_{32}$ and $C_{16}H_{34}$, and still higher we have true solids, such as paraffin wax, the highest member of the group isolated being $C_{35}H_{72}$. In order to work upon as nearly a definite compound as possible, Thorpe and Young took paraffin wax for their experiment, and distilled it in an iron mercury bottle connected with a second by a bent tube carrying a pressure gauge and stopcock. The distillation was carried out over an open coal fire, one bottle containing the paraffin being heated, whilst the other acted as a condenser. In about four or five hours the distillation was completed, the pressure throughout being kept at 25 lb., and a magma of oil and unaltered paraffin resulted, which could be liquefied completely by the warmth of the hand. Four litres of liquid hydrocarbons were obtained from $3\frac{1}{2}$ kilos of paraffin wax, and on a preliminary fractionation gave -

Below 100° C.	0·3 litre
„ 100-200 C.	1·0 „
„ 200-300 C.	2·7 „

Repeated distillations of the portion boiling below 100° C. resolved it almost entirely into three fractions :—

(1) 32-38° C., consisting of pentane and amylene.

(2) 65-70° C., consisting of hexane and hexylene.

(3) 94-97 C., consisting of heptane and heptylene.

Members of the acetylene and benzene series were absent.

Extended experiments with portions distilling from 100° C. up to 300° C. and the solid hydrocarbon left above 300° C. showed them to be mixtures of saturated hydrocarbons and olefines.

In the fractions distilling below 100° C. these two classes of bodies were in nearly equal proportions, but above that temperature the proportion of paraffin hydrocarbon to olefine became gradually larger as the molecular weight increased, and from this it appears that the primary action in "cracking" is a resolution of the heavier paraffin hydrocarbons into simpler members of the paraffin and olefine series.

ABOLITION OF LEVEL CROSSINGS ON AMERICAN RAILWAYS.

The following particulars respecting the abolition of level crossings on railways in America were given recently in an interesting article entitled "Eliminating Grade Crossings" published by the *New York Times*. From this we learn that much has been done in the States during the last few years for safeguarding the public at dangerous crossings by causing the roads to pass either below or above the railway lines.

Although the English standard of safety cannot yet be said to have been reached, it should be remembered that the conditions which obtained in the two countries when railways were first made were completely different. In England, for instance, the first lines were built through a well-populated country, in the face of considerable opposition from public and private landowners. In consequence a high standard of safety was insisted on at places where the lines crossed private roads and public highways.

In America, on the contrary, the construction of the railroads went ahead of the settlers free from such restrictions, the main object being to open up the country by getting the lines made as quickly as possible. Every road crossing was at the level of the rails. In many of the Western cities the lines were laid through the main streets. Now that the country has grown up to the railways, and the highway traffic become more dense, each unprotected crossing becomes a danger to the public.

In the State of New York alone it is estimated that out of upwards of 10,000 railway crossings no fewer than 6,800, or about one for every $1\frac{1}{4}$ mile of railway, are entirely unprotected, except for a simple notice board. In the other States of the Union conditions are probably less satisfactory.

A report issued by the National Highway Protection Society for 1914 states that 199 persons were killed at level crossings that year in the State of New York alone, as compared with 124 and 107 respectively during the two preceding years. Of these 66 per cent. were pedestrians.

No fatal accidents to tramcar passengers appear to have occurred during the last two years at railway crossings. This is evidently due to the existing law in this State, which requires all tramcars to stop and the driver to be assured that the way is clear before proceeding on his journey. Had such regulations been in force also for motor-cars, the lives of 64 persons who were killed last year might probably have been saved.

The abolition of level crossings in the State of New York, and especially on Long Island, has made considerable headway during the last ten

years. There are on Long Island about 960 crossings, protected and unprotected, to about 400 miles of railroad. That is to say, on Long Island there are about 9 per cent. of the entire number of crossings in the whole State of New York, while the area of the island is but 2 per cent. that of the State, and the railway mileage about 4½ per cent. When to this is added that 20 per cent. of the population of the State live on Long Island, it will be readily seen that the problem is more acute there than in any other section of the country. It was especially for the relief of this territory that a comprehensive scheme was elaborated for the elimination of practically every level crossing within the limits of towns.

A beginning was made some years ago, and work is still in progress, whereby the lines are in some places raised and in others lowered, in order to suit the particular requirements of each locality.

The Long Island railroad is but an example of what the railways are doing throughout the country, according to their ability and as conditions warrant. The New York Central has within a few years elevated its lines through the City of Yonkers, and is conducting considerable elimination work throughout its network, and many other railway corporations are following its example at a cost of many millions of dollars.

In New York State and in several others the abolition of level crossings has been hastened and encouraged by the wise policy of the State and local authorities in contributing to the expenses of such work.

To get rid of approximately 9,000 level crossings in New York State, at a moderate average of 20 thousand dollars (£4,000) each, will necessitate a total expenditure of 180 million dollars (£36 millions sterling). This is a large sum to be spent for an object not directly remunerative to the owners of the railways; but by the method of co-operation, which has been so successful in New York State, it is hoped that in ten years' time only a few level crossings will be in existence, and these only on the unfrequented branches of the main arteries of commerce

PRECIOUS OPAL DISCOVERY IN SOUTH AUSTRALIA.

Although the present conditions in the less-known portions of South Australia are by no means favourable to systematic prospecting, several additions have of late been made to the known mineral wealth of the State. Recently the Government Geologist inspected, in Adelaide, a number of precious opal specimens which are reported to have been obtained in the neighbourhood of Stuart Range, to the westward of Anna Creek Station, by a party of prospectors who were in search of gold. Reporting to the Minister of Mines on these, the Government Geologist states: "The specimens were evidently secured from veins in the desert sandstone formation, and are quite the best obtained in South Australia. The general characteristics of the samples are in all respects similar to those exhibited by material obtained at White Cliffs, in New South Wales, where also the desert sandstone is the formation containing the opal. This new discovery in South Australia is a highly encouraging one, inasmuch as it has been made within the limits of a formation which occupies an immense area in the north-eastern quadrant of the State. This desert sandstone formation, which is of upper cretaceous age, has not hitherto contributed to the mineral production of South Australia, and the new discovery therefore adds another geological horizon to the list of those which are worthy of the attention of prospectors. Precious opal is always associated with opal possessing no commercial value. But the samples which I have just inspected contain a proportion of the precious variety that is more than sufficient to justify careful and systematic prospecting. It is reported that the deposits extend over a very large tract of country, some thirty square miles having been taken up under search licence.

DETERMINING TOTAL SULPHUR IN RUBBER.

In order to learn whether or not the methods recently published for the determination of sulphur in rubber were any improvement over the Waters and Tuttle method, now in use at the Bureau of Standards, United States Department of Commerce, that Bureau has made a study of the methods, and has recently published the results of the study in a technological paper.

The methods investigated were those of Spence and Young, Deussen, Alexander, the Joint Rubber Insulation Committee, Kaye and Sharp, Frank and Marckwald, and Waters and Tuttle. These were subdivided, according to the method of attack, into three classes direct solution, direct fusion, and solution and fusion methods. A large number of determinations were made on a number of samples, two of the latter being of known composition which were specially prepared at the Bureau of Standards.

The methods which have been compared may be divided into two classes, viz., those for the determination of the total sulphur and those for the determination of sulphur other than that present in the insoluble sulphates. It was found that the methods of the second class could not be relied upon to give accurate results.

The direct solution methods, those of Spence and Young and Deussen, involve the use of concentrated nitric acid. This was first suggested by Henriques, but is objectionable because it gives rise to low results.

In direct fusion methods, those of Alexander, the Joint Rubber Insulation Committee, and Kaye and Sharp, are reliable only when the free sulphur content is low, and are therefore not applicable to routine analysis.

The solution and fusion method of Frank and Marckwald was found to be unreliable when the free sulphur was high. The Waters and Tuttle method was found to give satisfactory results and recommended for general use.

A new suggestion is offered, namely, to determine separately the free sulphur and the sulphur remaining after the extraction, reporting the sum of the two quantities as the total sulphur. This procedure eliminates the troublesome effect of the free sulphur upon the determination of the total sulphur.

RESOURCES OF THE CHENGTU DISTRICT.

The Chengtu district of the Province of Szechwan (China) comprises an area of approximately one hundred square miles, and includes such cities and market towns as Kien Yang, Lochi, Chiaokiatu, Kwaichow, Sison, Shi Chiao, Lungchuanyi, and others of less importance. The population of the city of Chengtu, the capital of Szechwan Province, is about 500,000, while the population of the Chengtu district above described is 2,000,000.

The Chengtu district imports a larger quantity and a better class of foreign goods than any other part of Szechwan Province. There are many large shops at Chengtu that handle foreign groceries of all kinds, clothing, shoes, hats, toys, medicines, toilet articles, hardware, and various other household supplies. Foreign wines, cigars, and cigarettes are sold in considerable quantities. Small sewing machines, as well as large ones for manufacturing purposes, are readily disposed of, and cotton gins and several lighting plants have also been sold there recently.

The chief exports of the Chengtu district are hides, silk, herbs for medicine, sugar, salt, bamboo, cotton, and rice. New industries also are starting and are making considerable headway. Cotton cloth is being manufactured to a greater extent, as well as ready-made clothing, hats, shoes, and leather goods of a general character. Many of these exports are sent direct to Japan, but most of them are sold to merchants in Chungking or Shanghai, who export a certain amount.

Shi Chiao is noted for sugar, while cotton and rice are shipped largely from Lochi. Rice is grown throughout much of the Chengtu district; the same may be said of sweet potatoes, peanuts, and maize. Oranges, peaches, persimmons, pears, and other fruits are largely grown—oranges chiefly in the vicinity of Chiaokiatu. As the Chengtu plain is watered by an extensive irrigation system, it can always be depended upon to supply regular and abundant crops. Wheat, rape, beans, peas, and millet are also grown as staple crops, especially on the plain, oats and buckwheat being likewise cultivated to a certain extent. Enormous quantities of vegetables are produced, chief among which are the turnip, carrot, cabbage, onion, and lettuce. Pepper, ginger, and mustard are largely used as relishes. Tobacco is extensively grown in this district, and is now being employed by a foreign company in the manufacture of cigarettes for local consumption.

While there are several small waterways traversing the region, they are navigable for large boats only during a certain part of the year. Rail transportation is much needed, and electric lines would probably be best at the present time. American engineers who have recently visited this district state that electric railways could not only be constructed with comparative ease, but would prove highly profitable from the very beginning. Cheap water-power could be obtained from the rivers, and the level character of the country would make construction extremely simple. A system of railways would stimulate industry and business to a wonderful degree, and would greatly reduce the cost of transportation.

As the district about Chengtu develops there will be an increasing demand for foreign machinery, says the United States Consul at Chungking in a recent report. Mining machinery is needed in the development of the region west of Kwanhsien, where lead, coal, silver, and copper deposits are said to be extensive. There is also a demand for machinery for the scientific refining of salt and sugar, and for the manufacture of paper, shoes, soap, candles, and many other articles. Modern sawmill machinery will eventually be introduced. Machinery for silk and cotton weaving could be used to advantage; much of the Tibetan wool that comes from Tachienlu to Chengtu could be made into fabrics at the latter city, where labour is cheap and water-power available.

A tannery with modern methods has already been established at Chengtu, but a larger plant is needed, and a considerable amount of foreign machinery will, no doubt, be added to the present equipment.

ITALIAN PIUMA-GRASS BROOMS.

Piuma grass is a tough grass used in Italy in the manufacture of brooms for sweeping highly-polished floors, for which purpose they are very satisfactory. It is a product of swampy regions, particularly in South-eastern Lombardy, Southern Venetia, and Northern Emilia, in which places it is said to grow abundantly. Mantua in Lombardy, according to the American Consul at Milan, is the centre of the trade in piuma grass. Peasants around Mantua gather it during the first three weeks in September, about two weeks before it begins to blossom. Soon after it is gathered it is spread on dry ground, and turned over frequently with wooden pitchforks until almost all the moisture has disappeared. It is then put up in packages of 22 lb. each, which in

turn are bound together so as to form bales of 220 lb. each.

Brooms of this grass are manufactured in Mantua and Cremona, and there are also a few factories in Milan. They are made in four sizes for the trade in Milan. The largest size is used for sweeping highly-polished floors, and is formed of three small bunches of the grass, each tightly bound at the stems, generally by means of a vegetable binder, such as raffia. These bunches are placed side by side in a fanlike arrangement, and are tightly secured in that position by a wire near the handle, and by strong vegetable fibre just above the stems. The brush thus formed is compact but soft, and does not scratch the floors upon which it is used.

The three smallest sizes of the brooms are made up of one single round bunch of grass, tightly bound with raffia to a handle. In making the largest brooms about a pound and a quarter of dry grass is used, and for the other sizes about three-fourths, one-half, and one-third of a pound respectively are required. Both the raw grass and the manufactured brooms must be kept in dark and very dry storehouses, as they are liable to blossom if left in a damp place. This is one of the great drawbacks of the article.

IRON-ORE SURVEYS IN THE PHILIPPINES.

The party sent out by the United States Bureau of Science, consisting of the Chief of the Division of Mines, one mining engineer, and one assistant, which has been engaged during the early part of this year upon a survey of the recently discovered iron ores in Surigao Province, has returned to Manila, and as soon as analyses of the samples taken can be completed a statement will be published as to the quality and extent of the Surigao iron ores.

The examination just completed involved the drilling of a total of about 650 metres (1 metre = 3·28 feet) of test-holes, distributed over an area of about 100 square kilometres (1 square kilometre = 0·3861 square mile). In this manner some 250 samples of the iron ore were obtained, from the analyses of which it will be possible to judge whether the ore is generally of good quality and whether the deposit is uniform in character.

According to a despatch received by the United States Department of Commerce from a correspondent at Manila, the findings of the engineer who first reported the existence of this deposit were confirmed in that the deposit was found to be singularly like the famous Mayari iron ores near Nipe Bay, Cuba, in its occurrence—that is, it is a great surface blanket of iron-bearing clay, which has resulted from the weathering and decomposition of the original rock. In the case of the Surigao deposit the parent rock is made up principally of the mineral serpentine.

The territory covered by the iron ore is almost barren when compared with the tropical country surrounding it, and consists of low mountains or hills, with precipitous slopes draining into canyon-like valleys. Although the hills reach an extreme elevation of only 300 to 400 metres, and most of them are less than 200 metres high, yet the vegetation is of the stunted and brushlike varieties common to extreme altitudes in the Philippines.

Huckleberries, for instance, which are found most commonly in the highlands of northern Luzon, grow profusely over the iron-ore deposit at elevations as low as 150 metres. According to the geologists of the Bureau of Science, this condition is probably due to the character of the soil and the abundance of rainfall of the ore deposit.

While the limits of the iron-ore deposits include more than 100 square kilometres and the ore is at places 30 metres thick, a considerable portion of the area is so eroded that the barren underlying parent rock is exposed. Over a still larger portion the iron-ore blanket is too thin to be of value. This condition, which will make necessary a reduction of the estimates of tonnage that were given out with the announcement of the discovery, is due to the precipitous character of the region, and to the excessive rainfall which prevails there. Had this portion of Surigao Province maintained itself as a plain or a level plateau, the iron-ore blanket covering it would have been less readily carried away by erosion and there would be present to-day a much greater tonnage of ore.

There are natural harbour facilities near parts of the deposit where safe ports could be established, and two river systems which afford water power possibilities.

INDIAN AGRICULTURE.

A volume summarising the multitudinous agricultural returns collected by local governments of India, and including the results of the periodical cattle censuses and crop reports for the whole of British India, has been issued by the Director of Statistics. It contains charts, diagrams, and a *resume* showing the strength and progress of Indian agriculture during the present Viceroyalty The number of cattle (bulls, bullocks, cows, buffaloes, and young stock) in India amounts to the enormous total of 130 millions, an increase as compared with the number a decade ago. The United Provinces account for 22 per cent. of the total numbers; Bengal, 19 per cent; Madras, 14 per cent.; Bihar and Orissa, 12 per cent.: the Central Provinces and Berar, 9 per cent.; the Bombay Presidency, including Sind, only 7 per cent. In the case of ploughs also the United Provinces come first, with 28 per cent. of the total (excluding Bengal, for which figures are not available), followed by Madras with 22 per cent.; Bihar and Orissa, 17 per cent.: and the Punjab, 11 per cent. respectively.

The total revenue from land, excluding cesses for British India, amounted in 1913 to over Rs. 32½ crores. The revenue per head was 7 annas in Bihar

and Orissa, 10 annas in Bengal, as against 33 annas in Bombay and 77 annas in Lower Burma. The area under crops in 1913 was 255 million acres, or an increase as against the previous year of 2½ per cent. of this total cropped area.

Food crops occupy 83 per cent., and non-food crops the surprisingly low figure of 17 per cent. Of the percentage under food crops (83) 80 per cent. is food grains; fruits and vegetables 2 per cent., and sugar only over 1 per cent. Of non-food crops (17 per cent.), 7 per cent. is under fibres, *e.g.*, cotton and jute, and 6 per cent. under oil-seed. Of the gross area of British India nearly 617 million acres (36 per cent.) is the net area cropped, 8 per cent fallows, 19 per cent. culturable waste other than fallows. The area not available for cultivation is only 24 per cent., and forests are 13 per cent. The proportion of cropped to total area is highest in the United Provinces (53 per cent.) and lowest in Sind and Burma (13 per cent each). The percentage for Bengal, Bombay, and Bihar and Orissa is 51 per cent.; for the Punjab, 40 per cent.; and for Madras, 38 per cent.

The total area irrigated is the large figure of 15½ million acres, and while the proportion of irrigated to total cropped area is as high as 82 per cent. in Sind, 47 per cent. in the Punjab, the percentage in Bombay, Central Provinces, and Berar is as low as 4 per cent.

RUSSIAN EXPLORATION IN THE ARCTIC SEA NORTH OF SIBERIA.

The two Russian ice-breakers, the "Vaigatch" and "Taimyr," to which vessels was due the discovery in 1913 of the previously unknown islands to the north of the Cape Chelyuskin, the northernmost promontory of Asia, succeeded in the course of last summer in carrying out a fresh voyage of discovery under the command of Captain Vilkitsky. Starting from Vladivostok the vessels made for the north-eastern passage, which had not been traversed since Professor Nordenskiold's notable journey in 1878 79 on board the "Vega." The telegrams handed in at the wireless station erected at the Yugor Shahr gave a clear description of Vilkitsky's cruise. During the course of their trip the "Vaigatch" and the "Taimyr" discovered a new island S E. of Bennett Island in 76° 10′ lat. N. and 153° long. E. The two islands proved to be much the same size and appearance, and it is curious that the crew of the "Jeannette," during their unfortunate expedition, failed to perceive the island which has just come to light, as they must have passed within thirty miles thereof in clear weather. After that the Russian expedition proceeded westward and explored the new land named after the Emperor, Nicholas II. land, situated north of Cape Chelyuskin and lying off the southern part of the coast, and discovered four small islands. On August 23rd the northernmost point of Asia was passed, and on the further side a dozen or so islets were discovered, some of which had been already visited and examined by Nansen. Further west vast fields of ice were encountered, and the two Russian vessels found themselves imprisoned in the pack west of the Taimyr peninsula. At the time of writing the expedition was not in any danger, being sheltered from the pressure of the ice; unfortunately they were running rather short of fuel, and had only about three weeks' supply left. Captain Vilkitsky had accordingly wired for 400 tons of coal to be forwarded to Port Dickson, at the estuary of the Yenisei, and if this supply could not be arranged for, communications would be opened up with the "Eclipse," commanded by Captain Sverdrup, and wintering in that part of the Polar regions.

At the beginning of the year 1914 the Russian Government bought two Norwegian whalers, the "Hertha" and "Eclipse," for the purpose of instituting a search for the three expeditions of Sedof, Broussilof and Roussanof, which had set out for the northern island of Novaya-Zemlya in 1912, and whose fate was causing some anxiety The two whalers, commanded by Captains Johannof and Sverdrup, set out for the Arctic from Christiania on July 13th, 1914. Both were provided with apparatus for wireless telegraphy. From a wireless message received in Petrograd it appears that the "Eclipse" wintered on the north-west coast of the Taimyr peninsula, not very far from the spot where the "Baron von Toll" wintered in 1900 01. No mention was made by Sverdrup in his brief message of the Broussilof and Roussanof expeditions, from which it was inferred that no signs or traces of the vessels were apparent, and that these two explorers had perished like the first.

CACAO IN THE DOMINICAN REPUBLIC.

Cacao-growing has proved to be a most profitable form of agriculture in the Dominican Republic, and its cultivation has steadily increased during recent years. It is now the second crop in importance in the Republic, and in 1913, when low prices for sugar prevailed, it held the first place in the value of exports. New acreage is constantly being planted, and there is every reason to think that the increase shown in past years will continue.

According to a recent report by the United States Consul at Puerta Plata, most of the cacao grown in the Republic is produced in the Puerta Plata district, and it is expected that the 1915 crop in this district will be at least as large as that of 1914, which was approximately 37,121,000 lbs., valued at £684,580. At the commencement of the year everything pointed towards a record crop, but a prolonged dry spell coming at a critical time checked the development of the young pods, causing them to dry up. It is estimated that a loss of 20 to 25 per cent. has been sustained in this way.

The prices during the current year have been very satisfactory. Dominican cacao, which is

known to the trade as Sanchez, has fetched as much as 74*s.* per 100 lb. in New York this year, although at present the price is somewhat lower. Growers have received from 5*d.* to 7*d.* per lb. for their crop.

The principal harvest occurs in the months of April, May, and June. There is also a lesser harvest from November to February. The crop season varies somewhat with the location of the plantations. The greater part of the exports go to New York, and it is estimated that the exporter incurs expenses of 6*s.* 3*d.* per 100 lbs. in delivering the product in that city. The prospect of a good average crop commanding a high price is one of the most encouraging features of the general commercial situation in the northern half of the country.

THE MAHUA OR ILLUPEI TREE OF INDIA.

The mahua, malwa, mowha, mowa, or mowra tree of India is a large deciduous tree throughout the forests of Dekkan, Carnatic, West Coast and Central India, and Guzerat, stretching north as far as Oudh and Kumaun, and eastward across to Orissa, according to the American Consul-General at Calcutta. Though found in a purely wild state in many parts of India, the value of the flowers and fruit has caused it to be brought under more or less cultivation. The economic value of the tree lies in its edible flowers and oil-yielding seeds, although the gum or gutta that flows from incisions or abrasions on the stems shows an average of 48·9 per cent. gutta, 38·8 per cent. resin, and 12·3 per cent. ash. The bark also is used as a dye, while many of the properties of the tree are used to some extent medicinally. The mahua puts forth its leaves from February to April. Cream-coloured flowers appear in great clusters of thirty to fifty near the ends of the branches from March to April. About the end of March the flowers begin to arrive at maturity, and every morning about sunrise the succulent corolla tubes fall in great showers to the ground, which has been cleared of grass and underbrush and prepared for the harvest. This continues to the end of April, but usually the fall from a single tree is complete in seven to ten days. The flowers are then spread out and left to dry in the sun; in a few days they shrink in size, change in colour to a reddish brown, and their peculiar sweet odour becomes more apparent. These flowers are eaten extensively while fresh, but generally speaking they are dried thoroughly and cooked with rice and other grains. Sometimes they are completely dried and reduced to a powder, and in this condition are cooked in round cakes and mixed with a variety of food stuffs. Mahua is extremely sweet, and the ability to eat and digest it must be acquired. Few Europeans are able to eat more than one flower on a single occasion without having disagreeable after-effects. Sugar and molasses of a good quality are also made of mahua.

The art of distilling these flowers is a very ancient one. For the manufacture of spirits the flowers, when dried, are sold to village distillers or Government distilleries. The flowers are immersed in water for about four days; they are then fermented and thereafter distilled. The spirit produced has at first a strong, smoky flavour, but age remedies this. The seeds of the mahua, which succeed the flower from which the spirit is made, are extensively used for the manufacture of mahua butter, which is employed in the adulteration of ghee, for lubricating and illuminating purposes, and for eating by the native people. The method of expression is crude. The kernels are taken from the smooth, chestnut-coloured pericarp by being bruised, rubbed, and subjected to a moderate pressure. In the Central Provinces the kernels are pounded, boiled, wrapped in several folds of cloth, and the oil thereafter expressed.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

War Conditions.—Some twelve months of familiarity with warfare have bred nothing recognisably like contempt of its varied possibilities. Perhaps even more than was the case ten or eleven months ago, the war remains the universal explanation of the things that happen within the industry and the ready apology for all that does not happen. It encompasses all things about as effectually as ever it did, but a progress not easily measurable in exact terms is perceptible. The wonderment and the particular anxieties of the early days have departed. Problems which seemed only doubtfully soluble have been solved. A basis upon which both warfare and business proceed has been found, and, when seen in a perspective which assigns small things to their proper proportions, the industrial year may appear almost incredibly marvellous. At any rate, given a due appreciation of the complexity of the general industrial, commercial and financial arrangements, and of the weight of the blow that was delivered to them, astonishment must be felt that within so brief a time from August last textile industry should find its functions so near the normal. Allowing every credit to the extraneous assistance which supported the money market through its troubles, it is justifiable to infer that the crisis caught textile affairs in general in a strong and healthy state. Assuredly the recovery would not have been facilitated by the existence of an artificial or unduly extended position of private commitments. It cannot be professed that everyone has now all that he wants, but most people have more business upon hand than they would have dared to expect either from an *exposé* of the conditions beforehand or during the conditions of bewilderment obtaining in the early days of the war.

Wool Movements.—The most strikingly lucrative effects of warfare have been seen in connection with wool, and only partly because of the pressing

demand for army clothing. It is due to consumption for that purpose that British farmers are receiving about 50 per cent. more for their wool this year than they received last; but, for the present, values for their sorts of wool may have reached the zenith. There is a very perceptible slackening of demand for clothing for the British and Allied armies, and it is conceivable that no important further purchases upon their account will be made this year. Present interest centres rather in the fine merino wools ineligible for army clothing, such as have been used mainly upon the Continent. The production of these wools has remained practically constant, the consumption demand has doubtless lessened as a whole; but whereas users had formerly to look to the Continent for the main part of the manufactures they have now to turn to England, where there are not machines enough to satisfy the demand. The result is that, while merino wools in the raw state have advanced by a trifle of $7\frac{1}{2}$ per cent. or less between May and July, the same material in its first intermediate state has appreciated about 35 per cent. The price is 45*d.* for combed wool tops which fetched 27*d.* last December, and no abatements that can be made from this comparison of prices kill the suggestion of money for somebody, although the possibility of eventual losses from so extreme a fluctuation cannot be ignored. The experience of the wool manufacturing trade is unique, but neither its gains nor those of the jute and heavy linen trades can offset the misfortunes of the greater cotton and the much smaller silk trades. There have occurred cases in which men about equally deeply concerned in two branches of the industry have lost in unrealised profits as much with one hand as they have gained with the other. The effect is to stimulate their apprehension of what may follow from a decision to tax war profits at some exceptional rate.

Dearer Money.—Manufacturing concerns have not all large unemployed resources for investment, but it is known that many have taken their opportunity to invest in War Loan, as have textile operatives, through their unions and otherwise. The rate of interest is the same, or more than, manufacturing companies return upon their debenture capital, and is equal to that which cotton-spinning companies have been accustomed to give local depositors of money upon loan. The latter, of course, have had forthwith to raise their interest, usually to 5 per cent. People seeking accommodation from their bankers have had to pay 6 per cent. and upwards, and if this increase is to be as permanent as may be thought likely it marks a highly important change in the conditions under which business can be done. The hope must be that the heavier cost of finance is not to be singular to this country alone. So much of the export trade in textile goods and the import trade in raw materials has been done by virtue of the more favourable terms prevailing in this than in some other countries that a standing addition to the cost of money becomes an anxious matter.

German Patterns.—Conditions do not favour schemes for capturing German trade by making radical departures in methods of manufacture. The machine makers are busied in military engineering, labour is short, building is forbiddingly dear, so that the replacement of German goods has to proceed by way of substitution. In consequence, displays of patterns of German-made fabrics are robbed of direct value, and made into affairs of chiefly academic interest. The analysis of a variety of saleable German cloths used by ladies' tailors has been conducted at the Bradford Technical College, and the results put on view by the Textile Institute have attracted a certain amount of attention. The exhibits inevitably reflect the characteristics of the spinning machinery that has found most favour in Germany, and the analysis reveals the combinations that have been used to produce marketable enough fabrics. The patterns cater successfully for one branch of demand, and English patterns for another. Something to admire has been discovered in the German adaptation of the means to the end, just as Germans and others have found plenty to admire and to envy in British successes in making the most of the alternative materials and machinery employed. Like cannot profitably be compared with unlike; but at all events it does not appear that any higher order of ability or ingenuity has been at work than may be seen in English-made wool goods of several kinds. The Germans have been at least as far from success in duplicating English worsted goods as have English manufacturers from making such costume cloths as have been shown, and there is more reason to think that German makers have tried harder to imitate our methods than ever British manufacturers attempted to emulate methods which have been continually regarded as foreign to their aim. What German designers of costume cloths will do when it is no longer allowed to them to go to Scotland for their inspiration is unimaginable.

Cotton Explosives.—The idea that cotton rags cannot be used in substitution for "linters" and raw cotton in making smokeless powder receives some damage from the news that the German war raw material department has requisitioned the stock of rags throughout the country. As raw cotton in Germany has advanced to fully twice the price of the coarsest cotton yarns, it is by no means inconceivable that imported yarn should have been employed for nitration, and the order forbidding the manufacture of piece goods from yarns coarser than 16's English is not inconsistent with that probability. Soft cotton waste deprived of its grease is used in explosive manufactures upon a considerable scale, and there is nothing surprising in the fact that German stocks of that

article have also been commandeered. There are guns in action that are said to shatter the equivalent of three-fifths of a bale of cotton at every round. An American estimate, which cannot be guaranteed free of defects, assesses the current consumption of cotton in the manufacture of propulsive explosives at three million bales a year, or, say, 1,500,000,000 lbs. Of the quantity so used waste cotton must form a considerable proportion. Some 13 per cent. of by-product is made in carding cotton, and the waste is, of course, cheaper than the raw material from which it is extracted. Allowing even handsomely for errors, the contrast between the estimated normal consumption for explosives with that assumed to be going on at present is an imposing one — 123,000 bales as against the reputed three millions.

Domestic Rags.—The great public is more conscious of the advance in the cost of new clothes than of the much higher prices that ought to be procurable for any discarded woollen clothing. As these relics are given away, or bartered more commonly than they are sold, owners of them are not in the best position to seize such opportunities of real household economy as the state of the rag market should afford. Taking one grade of rags with another, the price can safely be said to have doubled since the opening of the war. It may be mere trifling with hope to mention the £100 or so that might be fetched by one ton of selected stockings; but not much less than £40 a ton can be got in the best market for a fairly homogeneous lot of domestic woollens. The dustman's occupation must have been singularly golden, although the more valuable rags hardly come his way. Doubtless the itinerants who exchange crockery and trumpery for cast-off clothing have had their share of a prosperity that has surged over the marine-store dealing, rag merchanting, and rag manufacturing trades. There is quite enough to suggest that capable management would make family rag bags and old clothes cupboards as remunerative at least as some kitchen by-products to which especial attention has been directed. High prices are perhaps more effective than a sense of public duty in provoking the dispersal of private effects, but sellers of accumulated rags may enjoy both. The liberation of the supply does something to cheapen new clothing, and in no case should the act involve a sacrifice.

OBITUARY.

Evan Arthur Leigh.—Amongst the passengers of the "Lusitania" upon her last ill-fated voyage was Mr. Evan Arthur Leigh, of Yewbarrow Hall, Grange-over-Sands. Owing to his splendid health and capabilities as a swimmer, it was for many days hoped that he had survived the disaster.

Mr. Leigh in his younger days was a keen cricket player, and considered the best amateur middleweight boxer of his time. He was fond of shooting and a great believer in all sports and athletics.

His father, the late Evan Leigh, C.E., of Manchester, will be remembered as the inventor of twin-screws and detached paddles for steamships. He also designed a complete and carefully worked out scheme for conveying railway trains across the Straits of Dover and other narrow seaways, etc. In addition to being the inventor of "coupled mules with putting-up motion," "self-stripping cards," "loose boss-top roller," etc., he was the author of "The Science of Modern Cotton-spinning."

It is a matter of some interest to note that, in his early days, Mr. Leigh was intimately associated with General Ricciotti Garibaldi (now so prominent a figure in the European conflict), who was partially indebted to Mr. Leigh's father—the late Evan Leigh—for his education, and from whom he also received his first sword.

Mr. Evan A. Leigh was born in Lancashire, and inherited his father's technical abilities, being himself the inventor of many improvements in the details of textile machinery in particular, and noted for his practical knowledge of the textile trades. His business houses are Evan A. Leigh & Co., Import and Export Merchants and Engineers, Manchester, and also Leigh and Butler, Boston, Mass., where he was recognised as a model employer.

He was among the originators of the Victorian Club of Boston, a member of the Boston Athletic Association, the County Club, the Exchange Club, Boston, the National Association of Cotton Manufacturers, and of the American Cotton Manufacturers' Association He was well known in Manchester business circles, and a member of the Manchester Constitutional Club. He belonged to the National Service League, being an ardent believer in the principles laid down by Lord Roberts, and was interested in the Navy League. He was elected a member of the Royal Society of Arts in 1908.

GENERAL NOTES.

Victoria and Albert Museum.—Two important loans have recently been placed on exhibition in the Ceramic Department of the Victoria and Albert Museum. The first of these is a large collection of European porcelain, chiefly English, lent by Mr. Herbert Allen and exhibited in Room 135. This collection includes, in addition to about 170 pieces of miscellaneous Continental pottery and porcelain, upwards of 900 specimens of English porcelain. Every English factory of the eighteenth century of which the productions can be identified is represented, as well as all those of any importance of the earlier part of the nineteenth century. A few outstanding pieces may be instanced as an indication of the character of this

splendid accession to the porcelain exhibits of the Museum. A set of three vases of Chelsea porcelain decorated in the Sèvres manner with subjects after Boucher on a claret-coloured ground, a rare mirror and stand with relief scrollwork, two peacock-feather plates, and two large tureens testify to the pre-eminence of this the most sumptuous of all English wares of the eighteenth century. Biscuit groups after Angelica Kauffmann and a set of gold-striped blue vases of Chelsea-Derby porcelain symbolise the more sober taste which came into fashion towards the close of the century. Two hexagonal vases with Japan patterns and salmon-coloured ground and three tea-services from the Worcester factory are typical of the good workmanship which is so praiseworthy a feature of its productions. A number of Bristol vases acquired from the Trapnell and other collections are interesting illustrations of the short-lived attempt to manufacture hard porcelain of the Chinese and German type in this country. Mr. Allen's collection is certainly one of the most important of English porcelain formed in recent years. It is hoped that a catalogue will be ready shortly. In the windows of the adjoining room (No. 136) may be seen the second of the two loans now under notice—a series of small medallions and panels of English stained glass lent by Mr. A. L. Radford, F.S.A. The majority of these are of a heraldic character and date from the Tudor period. The blazoury and badges of Henry VIII. and his family are exemplified in great variety. Certain of the panels are believed to have come from the palace of Nonsuch, built by that king near Ewell, which was demolished in the seventeenth century; others were formerly at Cowick Priory, near Exeter. It would be difficult to find in the whole history of stained glass anything to surpass in ordered balance of design and harmony and splendour of colouring some of these small armorial medallions.

The Unsinkable "Delmira."—The *Shipbuilding and Shipping Record* gives an interesting account of the remarkable fortunes of the ss. "Delmira," which was attacked by a German submarine in the Channel on March 24th. After eluding the enemy for nearly an hour, the captain and crew were forced to abandon her. The Germans then went on board the vessel and placed a bomb under the forecastle, which set the forward end of the vessel on fire. The submarine then discharged a torpedo, which struck the vessel in the engine-room on the starboard side, blowing a big hole in the shell and seriously damaging the machinery, but still the vessel did not sink. The Germans then left the "Delmira" and towed the three boats containing the crew towards the English coast for an hour and a half, until they sighted the ss. "Lizzie," when the submarine left, and the crew were taken on board the "Lizzie" and landed at Sandown Bay, in the Isle of Wight. meanwhile, the "Delmira" was drifting helplessly in the Channel, the fore-end burning furiously, and in this condition was sighted by a British destroyer, which came up with her, and, considering her a danger to navigation, put some shots into her with the intention of sinking the vessel. The ship still remained afloat, and she eventually drifted ashore on the French coast about ten miles from Cherbourg and sustained heavy bottom damage. The French naval authorities extinguished the fire and towed the "Delmira" to Cherbourg, where she was dry-docked and a large shield fitted over the hole in the engine-room made by the torpedo. After this was completed the vessel was then towed to Sunderland, all the machinery was removed to be reconstructed by the engine builders —Messrs. George Clark (Limited)—and the ship herself was towed round to the Tyne to have the other repairs executed at the dry docks department at the Wallsend shipyard. The "Delmira" was built by Messrs. Short Brothers, Sunderland, in 1905.

Wheat Supplies.—Some interesting figures are given by Mr. Alfred Akers, in a couple of articles reprinted from the *Outlook*, on "The World's Wheat and the Risk of Shortage." A very serious risk run by this country, and one which is especially dangerous in time of war, is our partial dependence on erratic foreign yields. Practically the whole of the world's exportable surplus comes from seven countries, in these proportions. Russia, 19·4 per cent., Rumania, 8·1 per cent.; United States, 20 per cent.; Argentina, 16 per cent.; Canada, 19·4 per cent.; India, 9·2 per cent., and Australia, 7·2 per cent. A few others combined contribute the small remainder. The annual variability of the yield in many of these countries is apt to be overlooked. For instance, the Canadian wheat crop for 1914 is estimated at nearly one-third less than that for 1913, showing a deficiency of more than one-half in the average Canadian exportable surplus. The Australian crop is not expected to provide more than enough for local consumption and seed; the Argentina crop of 1913 14 was only up to 50 per cent. of expectation in many provinces; while Indian yields of corn are always precarious, though, fortunately, they are becoming less so. On the other hand, the British yield of wheat per acre is remarkably regular, and in view of this fact Mr. Akers pleads for a substantial increase in the British area under this crop. At present, out of 47,000,000 acres of cultivated land in the kingdom, only 1,800,000 grow wheat. 8,500,000 acres would, at the present average yield, produce all the breadstuffs which we at present require.

Correction.—In the table of "Volumes of Vapour from Petrol Hydrocarbons," in Professor Vivian B. Lewes's Fothergill Lecture on "Motor Fuels" (*Journal* of July 9th, 1915, p. 763, col. 1), the cubic feet of vapour per lb. of nonane were given as 22·9 instead of 2·29.

Journal of the Royal Society of Arts.

No. 3,270. VOL. LXIII.

FRIDAY, JULY 23, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

CHAIRMANSHIP OF COUNCIL.

On Monday, the 19th inst., at their first meeting in the new session, the Council elected Mr. Dugald Clerk, D.Sc., F.R.S., Chairman for the ensuing year.

SPECIAL WAR LECTURE ON "FIELD TELEPHONES."

The Council have arranged with Mr. Charles R. Darling, A.R.C.Sc.I., F.I.C., Lecturer in Physics at the City and Guilds Technical College, Finsbury, to give a special lecture on "Field Telephones," with experimental illustrations, at 4.30 p.m. on Wednesday afternoon, July 28th.

The lecture will be open to all Fellows of the Society, who can admit their friends personally, or by the usual tickets. Any Fellows requiring further tickets can apply to the Secretary, who will furnish them with any number they may desire for distribution. Tickets will also be issued gratuitously to any persons interested in the subject who may apply to the Secretary.

LECTURES ON "MODERN MUNITIONS OF WAR."

On Wednesday afternoon, July 21st, Professor Vivian B. Lewes, F.I.C., F.C.S., delivered the third and final lecture of his course on "Modern Munitions of War." The subject of the lecture was "Poison Gases and Incendiary Bombs."

On the motion of the Chairman, the Hon. Richard Clere Parsons, a vote of thanks was accorded to Professor Lewes for his interesting course.

The lectures will be printed in the *Journal* during the summer recess.

EXAMINATIONS.

The results of the Intermediate Examinations (Stage II.) held in May were sent to the centres on the 16th inst. The results of the Elementary Examinations (Stage I.) will be published next week.

The time-tables for the 1916 Examinations are printed on pages 790 and 791. The first examination will be held before Easter, commencing on April 10th and finishing on April 19th. The second examination will be held before Whitsuntide, commencing on May 29th and finishing on June 7th. The time-tables have been rearranged, and the subjects taken on the first four days of the Easter examination will be taken on the last four days at Whitsuntide, and *vice versâ*.

It will be seen that the following languages, Portuguese, Russian, Swedish, Chinese, Japanese, Hindustani, Dutch, Arabic, and Danish and Norwegian, appear in the Whitsuntide examination time-table only.

The total number of candidates examined in all these languages during the past six years amounts to 400; of these 185 were in Portuguese, 72 in Russian, 64 in Danish and Norwegian, and 44 in Swedish, while none of the other languages attracted more than ten candidates. So far as can be estimated, the cost to the Society for Examiners' fees, printing, etc., for the examinations in these languages for the years 1909 to 1914 inclusive, amounted to something like £450, while the amount received in fees was £50. It is therefore evident that each candidate costs the Society something over £1, and whether the value of the work done is equivalent to the expenditure is certainly doubtful. The old regulation, which has never been carried into effect of recent years, that no examination shall be held in a subject for which less than 25 candidates present themselves will, therefore, in future be enforced. Even under these circumstances the Society will suffer a loss, but at all events the loss will be lessened.

EXAMINATION TIME TABLE FOR APRIL, 1916.

	Monday, April 10. (7–10 p.m.)	Tuesday, April 11. (7–10 p.m.)	Wednesday, April 12 (7–10 p.m.)	Thursday, April 13 (7–10 p.m.)	Friday, April 14. (7–10 p.m.)	Monday, April 17. (7–10 p.m.)	Tuesday, April 18. (7–10 p.m.)	Wednesday, April 19. (7–10 p.m.)
Advanced Stage	Book-keeping. Précis-writing.	German. Commercial Law.	Accounting. English. Typewriting. (7.30 to 10 p.m.)	Shorthand (140 and 120 words per minute). (7.15 to 10 p.m.)	French. Company Law. Economic Geography.	Theory and Practice of Commerce. Spanish.	Banking. Economic History.	Economic Theory. Arithmetic.
Intermediate Stage	Typewriting. (7.30 to 10 p.m.) Economic Geography.	Book-keeping.	French. Economic Theory.	English.	Commercial Correspondence and Business Training. Spanish.	Arithmetic. Economic History.	Shorthand (100 and 80 words per minute). (7.15 to 10 p.m.)	German. Theory and Practice of Commerce. Précis-writing.
Elementary Stage	French.	Typewriting. (7.30 to 10 p.m.)	Spanish. German.	Shorthand (50 words per minute). (7.15 to 10 p.m.)	Arithmetic.	Book-keeping.	Economic Geography. English.	Handwriting and Correspondence.
Music			Harmony.					Rudiments of Music.

EXAMINATION TIME TABLE FOR MAY AND JUNE, 1916.

	Monday May 29. (7–10 p.m.)	Tuesday, May 30 (7–10 p.m.)	Wednesday, May 31 (7–10 p.m.)	Thursday, June 1 (7–10 p.m.)	Friday, June 2. (7–10 p.m.)	Monday, June 5. (7–10 p.m.)	Tuesday, June 6. (7–10 p.m.)	Wednesday, June 7. (7–10 p.m.)
Advanced Stage	French. Company Law. Economic Geography.	Theory and Practice of Commerce. Italian. Spanish.	Banking. Economic History.	Economic Theory. Arithmetic. Portuguese. Russian. Swedish. Chinese. Japanese. Hindustani. Dutch. Danish and Norwegian.	Book-keeping. Précis-writing.	German. Commercial Law.	Accounting. English. Typewriting. (7.30 to 10 p.m.)	Shorthand (140 and 120 words per minute). (7.15 to 10 p.m.)
Intermediate Stage	Commercial Correspondence and Business Training. Spanish.	Arithmetic. Economic History.	Shorthand (100 and 80 words per minute). (7.15 to 10 p.m.)	German. Theory and Practice of Commerce. Précis-writing.	Typewriting. (7.30 to 10 p.m.) Economic Geography.	Book-keeping.	French. Italian. Economic Theory.	English. Portuguese. Russian. Chinese. Swedish. Japanese. Hindustani. Dutch. Danish and Norwegian. Arabic.

PROCEEDINGS OF THE SOCIETY.

FOTHERGILL LECTURES.

MOTOR FUELS.

By Professor Vivian B. Lewes, F.I.C., F.C.S.

Lecture III.—Delivered March 1st, 1915.

"Cracked" Spirits.

Thorpe and Young showed that by "cracking" a definite hydrocarbon belonging to the higher members of the paraffin series under a pressure of 25 lb., and at a temperature that could only have been as much above its boiling-point as was represented by the increase caused by the pressure employed, it was possible to split it up into the whole series of paraffins and olefines containing a less number of carbon atoms in the molecule than the body taken. Further, they showed that the two series of hydrocarbons were present in the portion of the resulting oil boiling below 100° C. in nearly equal proportions, but that in the higher fractions the amount of saturated to unsaturated hydrocarbon became higher and higher.

Important as these conclusions are, a study of the original memoir shows other deductions that may be made from the results of their experiments of quite as great value.

In the formation of simpler hydrocarbons from more complex, the important factor which governs the course of the reaction and the nature of the new compounds is the degree of temperature employed. This is not given in Thorpe and Young's paper; but the specific gravity of the paraffin-wax and also its melting point were carefully determined, and the pressure under which it was distilled was 25 lb., and from these we know that the temperature used in the action could not have been much over 300° C., and it would be quite safe to say between 300° C. and 400° C. At this temperature the reaction would be a dissociation, not a decomposition, the difference between the two being that in the former case, under favourable conditions, recombination would take place between the products to form the original body, whilst in a decomposition the products remain separate.

That it is dissociation acting in this case is shown by the fact that if the paraffin-wax was heated in a straight sealed tube for twelve hours no change in melting-point or composition ensued, but when transferred to a bent tube and distilled backwards and forwards six times it became completely liquid.

In the straight tube, all at the same temperature, there was no separation by condensation of the dissociated parts of the molecule in the vapours, and they recombined, but in the bent tube each distillation and separation built up lighter compounds, which were not dissociated again at the temperature and pressure capable of divorcing the groups of the heavier molecules. The fact that a temperature that will dissociate a heavy molecule is insufficient to break up lighter ones is made clear by the authors, who took the fraction of oil boiling at about 255° C. from a previous make of cracked hydrocarbons and distilled it backwards and forwards in the bent tube twenty-one times without altering its boiling-point or bromine absorption. Indeed, they went so far as to say: "It appears that only paraffins boiling at an extremely high temperature and those usually solid under ordinary conditions are thus susceptible of decomposition. The readiness with which they yield liquid hydrocarbons appears to depend upon the complexity of their constitution."

They were undoubtedly right *for the temperatures they employed*, but neither they nor the many who have devised cracking processes since have grasped fully the fact that every simplification of the hydrocarbon molecule requires a higher temperature for its further dissociation, and that where an oil is cracked, the largest portion of which distils at 200° C., one must use a temperature liable to overcrack, *i.e.*, decompose the fractions of oil distilling at 300° C., with the resulting formation of tar, gas, and choking with carbon.

Starting with the assumption that Thorpe and Young's experiments were carried out at a temperature probably about 300° C. to 400° C. and under a pressure of 25 lb., we have the conditions under which a heavy paraffin hydrocarbon of uniform or nearly uniform composition could be cracked into liquid hydrocarbons with but little gas and no residue of carbon, and as at the present time the great interest of such processes is in the percentage of motor spirit boiling below 150° C. that can be obtained from the original material, it is important to note that from the figures given there must have been a conversion of 19 per cent. of the wax into spirit—an excellent result even as compared with what can be done in one cracking by some of the modern processes.

It seems from the memoir that neither the separation of carbon nor formation of tarry residues took place, as preliminary experiments

are described in which paraffin-wax in a bent tube was distilled in a gas-combustion furnace from the end containing the wax to the cooled end; then the tube was reversed and the distillation repeated, and after a dozen distillations the distillate remained perfectly liquid, and consisted of a mixture of saturated hydrocarbons and olefines. This is evidently the primary action that takes place, and in the commercial application of the process complications in the results are introduced at once by the use of a mixture of hydrocarbons instead of a simple compound, so that to get dissociation of the main fractions decomposition of the higher ones has to be faced.

Directly decomposition begins to take the place of dissociation the fact is made manifest by the evolution of gas—one cannot have satisfactory conversion unless some gas is being evolved. That is to say, the temperature must be high enough to bring about incipient decomposition in the heaviest molecules in order to ensure dissociation in the most abundant and lighter compounds; but excessive gas means not only heavy waste of hydrocarbons, but thickening of residue by tar and deposition of carbon.

The amount of gas evolved, when it can be measured, is as good an indicator of the correctness of the temperature as an analysis of the gas is of the character of the conversion. The quantity and character of the gas evolved, of course, will vary with the oil used, but as long as it is a mineral-oil residue the results are fairly concordant for the same temperatures.

The class of oil most often employed for cracking work is the fairly cheap grade after the benzene and lighting oil cuts have been taken off, such as "solar distillate," and an experiment that affords a good deal of information is the simple cracking and decomposing of such oil by dropping it into an iron retort heated to definite and carefully maintained temperatures, in much the same way as if the object was to make oil gas. Under these conditions the volume of gas evolved indicates when decomposition commences and its degree, whilst an analysis of the gas shows the ratio of saturated to unsaturated hydrocarbons.

Thorpe and Young showed that when the action was dissociation only, *i.e.*, the perfect condition we desire to aim at, the proportions of the saturated and unsaturated hydrocarbons boiling below 100° C. were nearly equal; and I find that when decomposition has just started the same thing is noticed in the gas, whilst as decomposition increases with temperature, more rapidly with unsaturated than with saturated hydrocarbons, the ratio of these to the unsaturated rapidly increases as decomposition becomes excessive.

Taking a "solar distillate" oil with a gravity of 0·865 and a flash-point of 149° F., and allowing it to drip slowly into a retort heated to a known temperature, no decomposition will show until about 400° C., when gas will begin to be evolved, and will increase in quantity rapidly with rise of temperature until about 1000° C. is reached, when it is loaded with soot, and all the hydrocarbons are undergoing rapid decomposition. The volume of gas evolved per gallon of oil treated is shown by the following table:—

Temperature of retort—	500° C.	700° C.	900° C.	1000° C.
Cubic ft. of gas per gallon—	12	60	72	84

The analyses of the hydrocarbons in the gas given off at various temperatures are:—

	500° C.	700° C.	900° C.	1000° C.
Unsaturated hydrocarbons .	39·13	36·56	36·55	22·04
Saturated hydrocarbons .	42·41	49·45	49·45	54·83
Acetylene . . .	0·05	0·08	0·38	0·46

For such an oil cracked without pressure 500° C. would be the temperature likely to give the best results, as we see from the table that only 12 cubic feet of gas per gallon are being formed, so that the wastage of oil is small, whilst the proportions of saturated and unsaturated hydrocarbons are near together, and reflect the proportions in which they would be formed in the liquid residuals.

Having thus fixed the best temperature under ordinary pressure for the particular oil with which we have to deal, the next point to consider is how far pressure will aid us in carrying out the process on a commercial scale.

Cracking under pressure acts advantageously in two ways. In the first place, it increases the boiling-point and the temperature of decomposition, so that a temperature of 600° C. might be employed without any more wastage than at 500° C., and with a considerable increase in the conversion; whilst, in the second place, it causes the absorption and polymerisation of some of the nascent fragments of heavy molecules, and so adds to the volume recovered, giving a total conversion on the first cracking of 20 to 30 per cent.

It must not be supposed for a moment that because Thorpe and Young found the products

of cracking a simple paraffin hydrocarbon at a suitable temperature to be only olefines and simpler members of the paraffin series, the same easily traced compounds constitute a modern cracked spirit. We have been forced by commercial considerations to deal with a residue oil containing nearly all the members of the paraffin series from nonane upwards, and whilst we have been regulating our conditions of working to suit the largest fraction of the oil, we have been decomposing the higher fractions and undercracking the lower, with the result that the spirit obtained contains not only the primary products of dissociation, but also the secondary products of their further decomposition and interactions.

In the residues we find not only all the analytic products of the dissociation boiling above 150° C., but also the synthetic results of many polymerisations and secondary reactions that yield heavy compounds, asphaltic bodies, and, if decomposition has gone too far, tar pitch, and carbon.

The interesting class of hydrocarbons known as naphthenes is largely represented both in the spirit and residues, and as these on decomposition break up into hydrocarbons of the aromatic series, if the temperatures used have been excessive, traces of these are also found, and the "cracked spirit" is a mixture of far greater complexity than the ordinary petrol.

So far I have dealt with the cracking of oil by heat aided by pressure, and before passing on to consider the many attempts that have been made to obtain improved results by modifications of the process, it will be well to see what has been done by "cracking" alone.

The earlier attempts to crack the heavier fractions of oil took the form of distilling under pressure, and by the use of a relief valve condensing at ordinary pressures, but in 1889 Sir James Dewar and Sir Boverton Redwood patented an apparatus for conducting both operations under pressure, so doing away with the objectionable feature of checking the passage of the vapour to the condenser, which must of necessity cause irregularity in the distillation, whilst condensation under pressure gives the enormous advantage that the lighter vapours, such as pentane, come down with the spirit instead of to a large extent escaping, which must always be the case with condensation at ordinary pressure and temperature. Unfortunately, the process was twenty years before its time, light spirit was a drug in the market, and commercial failure was the result; but what the success would have been had the patent been taken in 1909 is shown by the enormous amount of cracked spirit being made in America by the servile imitation of Dewar and Redwood's process employed by the Standard Oil Company. This fact emphasises the mysteries of patent law and the importance of a huge capital.

In a process which has been exploited here recently, and plant to carry out which is being erected, the oil is forced under pressure through a coil of heated tube, the pressure being kept sufficiently high to prevent the separation of any gas, and the diameter of the tube being so arranged in relation to its length that every part of the oil is subjected for a considerable time to the superheating. The tube is continuous, and after the cracking coil is formed into a second coil, water-cooled, in which the oil now containing the fractions of lowered boiling-point and dissolved vapours is brought back to a low temperature, and finally escapes through a loaded valve into the receiver, the light fractions being separated by subsequent distillation and the residual oil returned for further cracking. In this way, the first run through gives a conversion of about 22 per cent. of the original oil into fractions boiling below 150° C., whilst running through five times with removal of the light fractions after each run is claimed to give over 80 per cent. conversion.

In considering the commercial aspect of such processes the point that has to be watched the most carefully is the cost of handling, fuel, and power. At the oil-fields, where residual oils cost a penny or less per gallon, it may pay handsomely so to treat the oil as to get the highest possible conversion; but over here, with the oil costing at its cheapest 2½*d.* or 3*d.* per gallon, and the spirit having to be produced at the works at 8*d.* in order to give it a chance of competing successfully with petrol, it is clear that unless the process is carried out on a very large scale, establishment costs, labour, fuel, etc., will soon eat into the profits, and as each run with residues shows a smaller and smaller conversion, not to mention the increased tendency of choking the coils, there is an economic limit to the recovery that is quickly reached.

A very interesting phase of the motor-fuel question is the combination of cracking with the recovery of very light spirits from the gases escaping from the oil-wells. For some years past "wet" gases, *i.e.*, natural or well gas containing the vapours of pentane and

hexane, have been cooled and compressed in order to condense the highly volatile hydrocarbons, and these in turn dissolve propane and butane, which are gaseous under atmospheric conditions; this gives a liquid of very low specific gravity which is too "wild," *i.e.*, evaporates too quickly, for motor work, but which, mixed with grades of spirit too heavy to work well as a motor fuel alone, gives the necessary vapour pressure and elasticity in running, whilst the heavy spirit retains the more volatile portions and prevents over-evaporation. In the States the residue oils are largely cracked to a heavy grade of spirit, and this, when touched up with the lighter spirit, makes an excellent motor fuel that can be sold cheaply, and is used extensively for agricultural work in the West.

Very much on these lines, but elaborated in a beautiful way, is one of the most interesting and successful processes that have been brought forward for the manufacture of motor fuel from heavier grades of oil. At a meeting of the Petroleum Technologists, held on February 18th last, Mr. W. A. Hall gave a full description of his process, and I would recommend those interested in the subject to consult the original paper. In brief outline the system adopted is as follows:—

"The oil is fed, at a rate exceeding seventy gallons per hour, through inch tubes of not more than 300 ft. in length, under 50 lb. to 75 lb. pressure, and so throttled that the speed of the vapour through the tubes exceeds 5,000 ft. per minute. The oil is first vaporised in a coil, preheated in the flue by the waste heat of the products of combustion from the furnace, so that it enters the cracking tubes at a high rate of speed. The speed is so great that very little deposit can be formed in these tubes to choke them and interfere with the cracking action; but, as the passage of the vapours through the tubes occupies only about three seconds, no very extensive cracking occurs, as is proved by samples extracted at these points. The temperature read on a pyrometer, its thermo-couple being located in the centre of the tubular nest, is about 550° C.

"The vapours issuing pass into a vertical pipe of twelve or more inches internal diameter, and about 12 ft. high, entering it through a very confined space acting as a throttle, and preferably impinging against a baffle in the large pipe, so that the speed of flow is instantly reduced from about 6,000 ft. per minute to a very nominal rate. This converts the energy of speed into that of heat, a sort of degrading action, much the same as takes place in a throttling calorimeter, the temperature actually increasing some 30 C., notwithstanding the expansion due to a reduction of pressure from 50 lb. or 75 lb. to about atmospheric. Hence we have in this large pipe, which is well insulated, a temperature well above that existing in the inch tubes of the cracker, and as the speed through this large pipe is comparatively slow, a large amount of cracking therein takes place with no extraneous application of heat, affording no chance for a superheating of the vapours to a temperature higher than that at which cracking takes place.

"By this method the interior of the mass is hotter than the exterior wall of the container, and all the vapours in their upward passage are working towards a cooler condition, thus preventing local superheating, which has always produced the largest amounts of fixed gas from what would otherwise have been condensable product of the character most desired in motor spirit.

"The pipe is filled with small pieces of thin tubing, which present an enormous surface and are found to collect any carbonaceous deposit.

"One might think that this very large chamber with all its surfaces, and with the slow passage of vapours through it, would act as a dephlegmator rather than a cracker, but in actual practice, even with oils of a gravity exceeding 0·960, and some very high-boiling fractions, no liquid condensate has ever been collected from the bottom and the higher the rate of feed of oil, at the same temperature in the cracker, the higher is the temperature in this secondary cracker.

"The actual temperature of the vapour in the lower portion of this receptacle may exceed the external temperature of the tube near its exit, but inside the furnace by about 30 C.

"From this receptacle the vapours pass through dephlegmators that separate all fractions boiling below the chosen point of cut, and the vapours and gases passing on are conducted without further condensation, and at a depression, into a mechanical compressor working under 70 lb. to 100 lb. per square inch, and then condensed through a cooler under that pressure. The object of the compressor is two-fold. Firstly, and of least importance, it is a means of drawing these vapours at substantially atmospheric pressure through the secondary cracker and the dephlegmators; and, secondly, it is a means of chemically attaching to the

condensable liquid the gases that would otherwise be permanent.

"That any chemical combination between such gases and liquids could thus take place has provoked much question and scepticism, and has led to very extensive tests. It was generally contended that its function could be only that of creating a solution of a gas in a liquid. That an actual and important chemical reaction does take place has now been established to the satisfaction of some of our best experts."

So far I have dealt with the cracking of oil alone, but during the past ten years several processes have been devised in which steam or water has been introduced with the oil into the cracking ducts, the idea being that hydrogen from the water would affix itself to the heavy hydrocarbons and hydrogenate them into lighter hydrocarbons. To aid this action catalysts have been frequently used, nickel being the most popular.

The idea of the use of nickel as a catalyst is twenty-seven years old, as in 1888 Ludwig Mond took an English patent (12,608 of that year) in which he mentions the treatment of hydrocarbons together with steam by passing them through heated vessels containing firebrick or iron oxide, and he states that if metallic *nickel is used in place of the iron oxide, then only a moderate temperature is required.*

About 1900 Sabatier and Senderens studied the action of nickel and other metallic catalysts on the hydrogenation of oils, and in the following years there were many more patents taken covering its use. Still later there were a large number of patents taken in America by Dr. Day, Ellis, Kayser and others dealing with the use of nickel as a catalyst.

Mond, Sabatier, and Senderens all recognised that such surface action as the nickel exercised took place only at temperatures below, at any rate, 300° C., but the more recent exploiters of the idea have drifted back to the heats one would use for cracking, not for hydrogenation. It may have been my ill-fortune, but in such experiments as I have made I have got just as much and sometimes more conversion when using the oil alone as I obtained by using water or steam and nickel surfaces at the temperature prescribed (about 600° C.).

I strongly suspect that at the temperatures employed the steam and water play a purely mechanical part, and simply break up the oil volume and hurry the cracking liquid through the hot zones, incidentally forming magnetic oxide with the iron of the ducts, whilst the hydrogen so liberated does not hydrogenate the oil, and is found in the gas. The nickel seems only to act at this temperature in reducing the volume of flowing oil into thin streams, and by its conductivity helping the transmission of heat to the oil.

All cracked spirits differ from petrol in the sickly alliaceous odour they possess; which is the more disagreeable is purely a matter of taste. This smell is due to certain unsaturated hydrocarbons, and to remove it by acid treatment would not be commercially possible owing to the loss in volume that would be incurred: but there is one advantage that may be placed to the credit of the "cracked" fuel, and that is that you nearly always find it 10 to 20 per cent. more powerful than petrol, as its specific gravity for a given range of fractionation is always higher, and so there is a greater weight to the gallon.

One of the troubles of the maker of cracked spirit is that it often has a yellowish colour that is difficult to get rid of; this is due to a naphthene hydrocarbon "cyclopentadiene"—which polymerises on standing for some time in light, forming resinous bodies, and causing sticking of valves in use. Indeed, the presence of very high percentages of unsaturated hydrocarbons (shown by bromination) frequently gives rise to this trouble.

I have already pointed out the great complexity of the mixture of hydrocarbons in such spirits, and it is often found that amongst the residues, especially when water or steam has been used in the cracking, there are oils that have distinct drying properties, and if used fresh make quite decent varnishes and vehicles for colours. Indeed, a patent was applied for in 1912 for converting heavy non-drying hydrocarbon oils into drying oils. As far as I have been able to trace the action that gives rise to this it is that some of the higher members of the acetylene series, such as isoprene, C_5H_8 (hemiterpene), are formed and then polymerise to terpenes, $C_{10}H_{16}$, which on standing, especially in light, gradually absorb oxygen and become converted into resinous bodies, the drying power being then reduced and the colour of the oil darkening. There is very little doubt but that some isoprene is formed, and as this is an excellent starting-point for the synthesis of artificial rubber, we may some day see the cracking of oils providing tyres as well as fuel to the motor-car!

The chemistry of the tars and residues from cracked oils offers a field for research every whit

as fascinating as coal-tar, and as the residues contain not only naphthenes but also heavy hydrocarbon molecules capable of being broken up into naphthenes by further and higher temperatures, it is worth consideration as to whether they could not be used profitably for the production of aromatic hydrocarbons, which are formed by the shedding off of hydrogen by the naphthene molecule. At the present time the demand for toluene is increased enormously for the manufacture of trinitrotoluene for explosive purposes, whilst if a State-aided attempt is to be made to capture the dye industry the demand for aromatic hydrocarbons—benzene, toluene, xylene, naphthalene and anthracene—will for some years be far in excess of the supply.

It will be remembered by many that in 1885, when the demand for benzol was high, Nobel Brothers, Liebermann, Burg, Salzmann and Wichelhaus investigated the possibility of obtaining aromatic hydrocarbons from petroleum residues, and obtained excellent results. The slump in the price during the past twenty-five years, which at one time brought benzol and toluol down to something like 6*d*. a gallon, led to these processes being abandoned, although I believe the preparation of aromatic hydrocarbons on a small scale is still practised from Russian petroleum.

Although the usage of the last fifteen years causes us instinctively to think of a motor-bus or trolly as a vehicle driven by an internal-combustion motor, everything points to steam-driven engines shortly challenging their supremacy, and probably ousting petrol for commercial haulage.

The opening years of the last century saw the inception of the mechanically propelled carriage running on the public roads, and about 1825 steam-driven stage-coaches were actually at work. Prejudice and legislative restrictions, however, offered but little encouragement, and in 1865 the Locomotives on Highways Act prescribed that the maximum limit of speed should be four miles an hour, with a man in front bearing a red flag; and although this was evidently intended to apply only to heavy traction, an appeal to the Court of Queen's Bench in 1881 placed every type of self-propelled vehicle under its restrictions, and killed all attempts at development until the repeal of the Act in 1896, by which time Germany and France, free from grandmotherly care, had got a lead in the development of the motor industry that took this country fifteen years to overtake. This forms an excellent example of the sort of "State-aid" our industries receive.

It was the invention by Daimler in 1885 of a motor using petroleum spirit and the perfection and application of it to vehicles by the French firm of Panhard and Levassor, who purchased Daimler's patents, that led to the remarkable developments that have revolutionised entirely our ideas on travel and traction and made the motor-car a necessity to civilised life. Great as has been the growth of the motor industry in the last ten years, its advance will be even more rapid in the next ten, but the most marked increase will be for what may be called commercial vehicles. Many large firms have already replaced horse haulage by the motor lorry and van, but the smaller traders, although they have realised the importance to them of following suit, have held back not so much from a desire to avoid the initial cost as from a fear of what the working expenses might increase to. They have noted the rapid advance in the price of petrol, and have listened to the prognostications of further rises in price to come, and have decided not to sell their horses and scrap their carts and vans until some guarantee was forthcoming that in the future their running costs would not be millstones round the neck of their business. The proposed substitutes for petrol have not yet made any great show on the market, with the exception of benzol, and its price is following perilously close in the wake of petrol, whilst the supply in the early future seems far from certain.

During the eighteen years that the motor-car industry has been advancing with such enormous strides, attention has been concentrated almost entirely on perfecting the internal-combustion engine for use with petrol, but steam-driven vehicles, especially for traction, have always had supporters who laboured to bring them to a degree of perfection that would enable them to compete economically with petrol for heavy work, and in this they were successful, but the first idea of steam ever entering into competition with the petrol-driven passenger vehicle came when, in 1903, the Clarkson steam buses appeared on the road. With the earlier steam-driven locomotives for traction, coke or other solid fuel was employed with hand-stoking, fire clearing, etc., and when automatic firing was attempted, jamming in the fuel feed, clinker and other troubles made their appearance, the result being that in the steam-driven motor-bus oil fuel burnt in suitable burners was

employed, and we all know how satisfactory the result has been.

During the past year, however, a further development has been introduced by the successful adoption of a new form of coke-fired boiler and fuel feed, designed by Mr. Thomas Clarkson, the managing director of the National Steam Car Co., in a motor-bus fitted with it, which has been running for some months past in regular work with the other vehicles belonging to the line, and has given perfect satisfaction.

Another similar boiler was fitted to a motor lorry and submitted to the Royal Automobile Club, who ran it under their open competition rules to Brighton and back on two consecutive days and on the results of the trial the firm was awarded the Dewar Trophy for the most meritorious performance in automobile engineering during the year ended October 15th, 1914, Mr. Clarkson having earlier in the year been awarded a silver cup by the Commercial Motor Users' Association. The fuel used was broken coke passing through a 2-in. mesh and held by a 1-in. mesh, and on the first day the consumption worked out at 0·62 lb. per ton mile gross, and on the second day 0·56 lb. per ton mile, or an average of 0·59 lb. With coke at 18s. per ton, a price at which the Gas Light and Coke Co. will supply any quantity carefully graded, this works out at about 17 ton miles gross for 1*d*. as the fuel cost.

In a trial of this sort, with the speed kept at an average of twelve miles an hour, and the road stoppages amounting only to thirty-two minutes on one day and twenty-four minutes on the second for a run each day of 109½ miles, the fuel consumption per mile is, of course, less than with a motor-bus in heavy traffic and with constant stops, but even under these conditions it would be safe to take ten ton miles per penny as the fuel cost.

Petrol of the grade used in a motor-bus would be contracted for in enormous quantities by the big companies at about 10*d*. per gallon, and 50 ton miles per gallon would be a good duty to obtain, so that the petrol-driven motor-bus would obtain only 5 ton miles per penny, and the fuel cost, therefore, would be double that of the steam-driven vehicle, whilst the small trader, paying 1*s*. 4*d*. per gallon for petrol, would obtain only 3·1 ton miles a penny, or less than one-third the power.

Gas coke is a home production the price of which is not likely to be affected in the same way as the price of petrol, the supply of which is in the hands of a few powerful and wealthy corporations. The price of all fuel must slowly rise as gradual depletion and increased consumption render the needed supplies more difficult to obtain, but the small trader will feel that he need fear no sudden rise in fuel cost of the character that for the past few years has prevented him adopting motor vehicles.

The newest type of boiler consists of a forged steel cylinder or drum, closed at the lower end, and fitted with a cover which may be removed for cleaning purposes. The cylinder is placed practically within a firebrick casing, and on the outside of the cylinder a large number of generating tubes project, the tubes being relatively short and of larger diameter.

This form of generating tube has superseded the horseshoe pattern which was formerly employed on the Clarkson steam motors as being easier to clean and repair.

It was first thought that no proper circulation of water could take place in these tubes, as only one end is open, but tests conducted with a glass tube prove that there is a good circulation. The circulation occurs in two phases. Below the boiling-point there are two currents in each tube, a lower current from the drum into the tube. As the water becomes heated it rises into the upper stratum and returns to the drum. The two currents in opposite directions may be clearly demonstrated by the addition of fine sawdust to the water. After the water has been raised to boiling-point a different circulation occurs. The tube being full of water at boiling-point, a further absorption of heat causes a copious stream of bubbles to flow back to the drum, thereby preventing further admission of water into the tube until the ebullition abates, owing to the water in the tube becoming used up. The tube never becomes dry, but is about one-third full at the lowest point when steaming rapidly at atmospheric pressure. The water in the boiler then rushes in and completely fills the tube, and the same cycle of operations is repeated. At atmospheric pressure the cycle occupies from three to five seconds. It is in the nature of pulsating circulation, and, incidentally, this is useful in assisting to keep the tubes clean. It has been observed that when a quantity of sawdust is placed in the far end of a tube it is rapidly dispersed by this action, and although it was anticipated that this might give rise to irregular steaming, and possibly cause priming in the boiler, no trace of this has been observed. The boiler steams remarkably well, and, if anything, better than the generator fitted with horseshoe tubes.

The firebrick casing which surrounds the boiler is enclosed in a sheet steel case, which in turn is surrounded by coke bunkers. There is a large shute on opposite sides of the grate, but although the base of the shute slopes at an angle of 30°, this is insufficient to convey the coke on to the grate, so push-rods or pokers are used, which slowly reciprocate and advance the coke into the combustion area *pro rata* with the combustion of the coke on the grate.

With regard to draught, where a chimney is permissible this is by far the best arrangement, and the natural draught is usually sufficient. For increasing the rate of steam an induced draught is provided by a steam jet in the base of the funnel. The use of a funnel is permissible on practically all classes of motors for the conveyance of merchandise, and also for single-deck omnibuses, but when passengers are carried on the roof a funnel cannot be employed. In this case the products of combustion are drawn underneath by a steam injector, and discharged at the rear of the vehicle on the offside, which, in the same way, has the exhaust of an internal-combustion chassis.

In conclusion, it seems a reasonable inference that the increasing activity in the production of petrol substitutes, with the use of benzol for motor-car work and the advent of new forms of steam-driven motors for commercial traction, will so ease the demand for petrol as to prevent any further rise in the price, whilst as soon as the depletion in the production of crude oil becomes a serious factor, alcohol will be ready to take its place and be available in any desired quantity to the end of time.

MUNITION METALS.

An interesting article is contributed to *Nature* by Professor H. C. H. Carpenter, in which he compares the resources of the Allies and the enemy countries in respect of metals which are regarded as essential for war purposes. The position is finally summed up as follows:

Of the ten munition metals the enemy countries can certainly produce five without having recourse to imports, viz., iron (the basis of the various steels used for war purposes), manganese, chromium, zinc, and lead; on the other hand it is doubtful whether they can produce sufficient nickel, copper, aluminium, tin, and antimony from domestic ores. In view of the fact, however, that they prepared for this war with extreme care and foresight, it may safely be concluded that large stocks, either of ores or the corresponding metals, or both, will have been accumulated in those countries. However confident the Higher German Command may ostensibly have been of a rapid victory, they will quite certainly have laid their plans to wage a prolonged war if it should prove to be necessary, and such plans will have included the accumulation of munition ores and metals of which their countries produced an insufficient amount. There is, accordingly, no adequate reason for concluding that the enemy countries are likely—in spite of the prodigious scale upon which the war is being conducted — to run short of metals which are essential for war purposes for some time to come. Moreover, it may safely be concluded that their technical metallurgists will have been mobilised in the direction of discovering substitutes for any of the above metals of which a shortage is liable to occur in a long war.

The Allies for their part can produce from their own resources all the iron, manganese, nickel, chromium, tin, and most of the aluminium they require, their command of the seas enables them to obtain, principally from the United States, their deficiencies in aluminium, copper, and lead. China furnishes the requisite antimony. Zinc is the only important munition metal of which there is a shortage, in spite of the great speed with which the American furnaces are being operated. Wherever it is possible to substitute another metal for zinc, it is of national importance that it should be done.

MARINE MOTORS FOR CHINA

Some information concerning the demand for marine motors in China is afforded by a recent report by the United States Consul at Swatow. He points out that although this part of Kwangtung Province is not so liberally favoured with natural waterways as some other sections nevertheless most of the chief centres of its more populous districts are accessible by water, and it is to this fact that Swatow owes its position among the ports of China. The streams afford the cheapest and most convenient means of transportation, available for both cargo and passengers. Boating for pleasure is not indulged in, and consequently when a Chinese buys a motor or a motor-boat it is with the intention of putting it to commercial use. For this market therefore, all engines should be of the heavy-duty type; they must burn kerosene or fuel oil, as gasolene is often difficult to procure and is very expensive; and they should have few moving parts and should be simple to operate.

There are no facilities for building modern water craft of any kind here, the power launches in use at Swatow having been constructed at Hong-Kong. Chinese buyers have no knowledge of internal-combustion engines, and consequently the selection of the motor is usually left to the builders of the boat. This condition of affairs would indicate that for such craft as are constructed at Hong-Kong manufacturers will have to get in touch with builders at that place if they desire to share in this market. The Consul states that for the present there are no schemes under contemplation for

increasing the fleet of motor launches in this district to his knowledge, but he is of opinion that it is only a matter of time until most of the steam launches will be replaced by motor ones, and also that new services will be established. Further, it will be in motor craft, constructed in accordance with local requirements, that extension will largely take place. The cost of operation, and even the initial cost, of a motor launch is less than that of a steam launch of equal capacity. As the Chinese become fully cognisant of these conditions, and as knowledge of the usefulness of motors increases, so proportionately will the demand increase.

The view is held by many that China, with its network of waterways, is bound to become a large market for marine motors, and is a field well worth cultivating. For manufacturers to gain a fair share of this trade it is necessary that they should acquaint themselves with its conditions and requirements. It must be remembered that boats to find a sale must conform to local requirements, and motors to find buyers must be suited to the uses for which they are intended.

In conclusion, it may be pointed out that the importance of manufacturers having their own representatives in some of the principal ship-building centres cannot be overestimated. If this method is not feasible, probably a plan of co-operation between manufacturers would lead to the formation of a scheme of joint representation and the establishment of their representatives at such important points as Shanghai and Hong-Kong. Were such a step to be taken, manufacturers could not only keep in touch with the development in construction of motor craft in China, but also would be in the position to offer guidance and instruction to their distributors at the smaller ports, which would prove no mean factor in developing business in a line wherein technical knowledge is required. The importance of assisting the Chinese in obtaining the requisite technical knowledge should not be disregarded.

A NEW OIL-BEARING NUT IN THE PHILIPPINES.

The Philippine Bureau of Science has recently been investigating a newly-discovered oil-bearing seed found abundantly in the Island of Catanduanes. It grows on a large tree and comes from a brown pear-shaped fruit that opens not unlike a cotton boll when ripe and emits the seeds. The seeds are rough of surface and of a dark brownish colour, about the size of a large dried prune and slightly kidney-shaped. The tree has not yet been fully identified, according to a correspondent of the American Bureau of Foreign and Domestic Commerce in Manila, but is thought to belong to the genus *Amoora* or *Dysoxylum*. Seeds belonging to other plants of that family are known to bear oil, at least of commercial value. The oil from the nuts under discussion has been tried in the manufacture of soap, and has been found to make a good commercial article. The nut or seed bears about 45 per cent. of oil, dark and fatty. This oil does not dry well, and is therefore not serviceable for paints and varnishes. It is not edible, having a bitter taste. Tradition shows that before the advent of petroleum the inhabitants of Catanduanes Island used the oil from this seed as a luminant. Since the importation of coal oil the local oil has fallen into disuse, and with no demand for it none is now expressed. In every part of the island old implements with which it was formerly manufactured for domestic use are to be found among the people. The method was to grind the seeds to a fine consistency in crude hand-mills of stone, or to grate it on rough surfaces. The resulting grindings or gratings were cooked and then put in a sack and subjected to pressure. In view of the increased use of the oil of the coconut in the manufacture of edibles, considerable interest is being taken in the new oil in the hope that it may be substituted for coconut oil in the manufacture of soap and for similar uses. The abundance of the seed from which it is expressed promises a valuable industry for the islands, in case the further experiments with the oil bear out those already made.

THE COOKING OF HAMS AND OTHER MEATS IN TINS.

Writing in the *Meat Trades' Journal*, Mr. Loudon M. Douglas, F.R.S.E., describes a new process of preserving meats — the vacuum process — which maintains the total weight of the meats, as well as preserving the flavour.

The preservation of whole hams, principally for export to tropical countries, has become quite a large industry of late, and looks like assuming larger dimensions in the future, and the new process can undoubtedly be applied to this purpose with immense advantage.

The process is in itself very simple, and can be very briefly described.

Each ham is boned out, and placed in a pear shaped tin, of a size suitable to the size and weight of the ham. The original shape is maintained, and when the boning out process has been completed some flavouring substances are lightly sprinkled over the cut surfaces of the meat, which is then pressed together, and placed in the pear-shaped tin, which it should fill tightly. The top of the tin is securely soldered on, and a small aperture, beside which a blob of solder has been placed, is left towards the narrow end of the cover of the tin The tin is now ready for treatment. It is placed in a vacuum apparatus consisting of a circular chamber, in which is a rotating platform actuated from the outside. This chamber will hold some twenty ham tins, and it is charged through a door in the side. When the chamber is fully charged this door is closed tightly, and the air of the chamber is exhausted by means of an oil-sealed pump. Obviously, in exhausting the air of the
